As you make the sweeping statement that our answer to Mr. Jones' letter (Number 543, January 24, 1907) is *entirely* wrong, we take it that this means that every statement made therein is erroneous. We are anxious to be set right and have no doubt that Mr. Jones would also appreciate further light on the subject. Accordingly, we should like to hear from you more definitely, taking up our answer point by point and demonstrating wherein it is not correct, particularly with regard to the experiments you mention having made. We should be pleased to learn the data you have been able to collect on this point by reason of your experience, as well as from the tests you have made.

Official Rating of Motors in Germany.

Editor THE AUTOMOBILE:

[581.]—In your issue of January 31, 1907, page 233, under the head of "German Motors Officially Rated," you give a formula for horsepower rating: N equals $.3 I D^2 S$, in which all the terms are metric and based on 900 r.p.m., with a mean pressure of 3.8 K-g. per square C-m., or 54 pounds per square inch. I believe this formula is incorrect as above printed. Are the cylinder and stroke expressed in millimeters, as is usually the case; if not, in what terms? Kindly explain by a concrete example with a four-cylinder Packard 5 x 5 1-2, and state the facts in horsepower, either in French or English terms.

E. J. COOK.

Cleveland, O.

The item you refer to in your letter was taken from a foreign exchange verbatim. We presume that as it is stated therein that all dimensions are metric, the bore and stroke are expressed in millimeters as you surmise, but cannot throw any light on the question. Nor can we say whether the formula is correct as set forth there or not. As a matter of fact, this phase of the question was not given any consideration in connection with the insertion of the item, but upon referring to it again cannot recall that we have ever seen a horsepower formula expressed in exactly that way. It is possible that it may have suffered in the translation. Not being sufficiently familiar with it we cannot accede to your last request, but if you wish to point out the error as it appears to you, giving a concrete instance from American practise such as you mention, we will be pleased to hear from you.

A Loose Steering Wheel and Some Other Questions.

Editor THE AUTOMOBILE:

[582.]—Will you kindly answer the following through the columns of your journal? (1) The steering wheel on our automobile is quite loose, having considerable play, so that it requires a movement of four or five inches before the wheels commence to turn. We have been informed that this is proper, but would like to have you tell us if it should be that way. (2) Would you please explain the proper way to connect up the circulation system on a two-cylinder opposed motor. There is a tank on top of radiator, and the pump is located between the motor and radiator. Should the cold water enter the top or bottom of cylinders? (3) What is the cause of a motor running fast and then slow, then gaining speed again without advancing spark or opening throttle? (4) We have had trouble from flashes of fire coming from carbureter when motor is running. This would occur when motor was running unsteadily, as suggested in question 3. The flashes would appear the same as a large spark, and would occur about every half-minute. Can you give us the cause of this?

Boyer City, Mich.

WENZEL BROTHERS & CO.

The steering wheel should not be as loose as you say it is, though it is less harmful to have it so than is commonly imagined. If the steering gear is of the irreversible type, as we assume is the case, the road wheels are rigidly locked in any position, irrespective of the movement permitted the steering wheel. Of course, with an inexperienced operator, or in any case at high speeds, the amount of manipulation required to start the change in direction might prove awkward, and thus cause an accident. It is practically impossible to make an irreversible steering device without some lost motion, because a very small movement in the gear itself will permit the wheel to move considerably. Most irreversible steering gears are of the worm-and-sector or the screw-and-nut type, and in many cases of the former they are not provided with any ready means of readjustment to take out wear. If the gear on your car is adjustable, you should adjust it; if not, it will be necessary to replace the worn parts. It is just possible that the looseness may be in the connecting-rod or drag-link joints, in which case there is no excuse for its existence, besides which it is apt to be materially more dangerous than lost motion from the other cause. Concerning the circulating system for the two-cylinder motor, it is impossible to

lay down any definite plan that will apply invariably, the variety of systems being almost as great as the variety of engines. As a general rule, however, the cold water should enter the bottom of the cylinders, preferably beneath the exhaust valves, so that it will exercise the maximum cooling effect at the hottest point of the motor and rise through the waterjackets through thermosyphon action as it is heated. The water should enter the top of the radiator, so that it will pass down as it is cooled, and the pump certainly should be located between the bottom of the radiator and the inlet to the waterjackets, for the simple reason that it is easier to pump cool water than hot. A motor that runs fast and then slow, fluctuating without spark movement or throttle manipulation may be suffering from an obstructed lead into the carbureter float chamber, so that the float chamber fills up slowly, permitting the motor to run under full power until the chamber is emptied again. The backfiring into the carbureter is due either to wrong timing of the valves, so that the inlets open before the exhaust, or else it is due to pitted valve seats, making tight closure impossible.

Lighting the Lamps by Electricity.

Editor THE AUTOMOBILE:

[583.]—Will you kindly describe in your columns how I can ignite the gas in my headlight by pressing a button near the gas generator, to save the inconvenience of getting out of machine to light up? They tell me one needs a coil, etc. Why can't I use the battery and coil plant I have on my auto for this purpose? I am a subscriber to your valuable journal.
W. L. K.
Pittston, Pa.

There is no reason why the headlights cannot be lighted without the necessity of using another coil, or for that matter without any coil, though the latter would probably not be found very practical. It would involve the use of a very fine piece of platinum wire placed across the tips of the burners, so that the gas would come in contact with it. The ordinary six-volt accumulator as used for ignition purposes will doubtless be found sufficient to bring a half inch or one-inch piece of platinum wire of about twenty-eight or thirty B. & S. gauge to incandescence, which will ignite the acetylene. A better way would be to cause the secondary current from one of the induction coils on the dash to leap a gap in the path of the gas from the burners; by connecting the gap in each headlight in series both could be lighted at once. Or, again, something on the style of what is known as an automatic gas-lighting burner could be employed; that is, one using an electromagnet to vibrate an armature, making and breaking contact and producing a spark in the path of the gas; this does not require an induction coil. In any case, there would be no necessity for a separate battery or coil where it is desired to use the latter, which would be by far the simplest method.

Some Interesting Dry-Cell Problems.

Editor THE AUTOMOBILE:

[584.]—One of my cars, a four-cylinder, air-cooled, came from the factory equipped with a battery of twenty No. 6 Columbia dry cells, wired according to a diagram sent with them, and showing the cells ranged in four rows of five in a row. Of course the cells were wedged tightly in place in the box. According to the makers of the car, this battery should have given the voltage of five cells and the amperage of ten on either side of the switch of the Splittdorf coil. I have found the dry cells used in this way very irregular, though I carefully test each new cell and always see that the sets are correctly wired. One lot will last for 500 or 600 miles, while the next, of the same amperage, will run out within a third of the distance. A neighbor of mine, who has a single-cylinder stationary gasoline engine, which he uses to saw cord wood, told me recently that at first he used No. 6 cells—in sets of eight, I think. He found them very unsatisfactory and short-lived, and now is using four very much larger dry cells. He declares that a set of the latter will last me nearly a year. Do you think I would get better service by using larger dry cells, and, if so, how many should I use? Do you think I am using too many of the No. 6? I will admit that those I use do pit or

corrode the platinum points of the tremblers very frequently. I tried a storage battery, out of which the makers said I would get at least 700 miles on a charge. As it petered out in exactly 75 miles, I went back to dry cells.
C. F. M. STARK.
Concord, N. H.

From the sketch you submit it appears that one of your sets of five cells is not connected in the circuits at all, so that on one side of the switch you get the voltage of five and the amperage of ten cells and on the other side get the voltage of five and the amperage of five cells. This, however, may be an error in your diagram, and in any case cannot have much to do with the troubles you describe. Judging from the lack of any invariable result, it would seem that something might be wrong with the wiring system, possibly a short circuit that sometimes causes the cells to run down rapidly. We assume, of course, that the switch is in good order and that you always switch off the current when you stop the motor. Stopping by the throttle, without cutting off the ignition, is a practise sometimes indulged in by the inexperienced, and if the engine happens to stop with the commutator making a contact the current supply will be run down very rapidly. The voltage of five cells is rather high for the ordinary coil, and eight cells, as used by your friend, if connected in series would quickly ruin the coils of most ignition systems, besides sending through enough current to pit the contact points. The advantage of large cells is that they have large current capacity without any higher voltage than smaller cells, so the use of four large cells might prove very successful. If the storage battery you use was discharged in traveling seventy-five miles, there was something too radically wrong for reasonable existence as a defect in a storage battery of even the poorest quality. In fact, your experience in this direction rather bears out the theory of some sort of a short circuit.

A Twenty-five Per Cent. Grade About the Limit.

Editor THE AUTOMOBILE:

[585.]—Will you kindly let me know what is the steepest grade an automobile can climb; also what is the grade percentage of the following hills: Fort Lee Hill, Eagle Rock and Jacob's Ladder?
Stamford, Conn.
SUBSCRIBER.

To our knowledge there is no data extant as to the steepest grade that an automobile can propel itself up, and, as a matter of fact, this depends so very largely on surface conditions that no general statement regarding it could be of value, for it must be evident that the vehicle's power to move forward on an incline is not limited by the angle of the latter alone, but by the hold the driving wheels are able to get of the road. Bearing in mind the fact that a 45 per cent. grade represents a vertical line, it is easy to see that no matter how much power can be concentrated at the rear wheels, a point is reached on grades ranging from 25 per cent. upward, where the force of gravity becomes superior to the maximum tractive effort. The average car has more than sufficient power to lift itself vertically at a fair rate of speed, if positive means for doing this, such as a drum and cable, were provided, so that it is not so much a question of horsepower as it is of holding power. To the average man a 25 per cent. grade appears to be a perilous approach to the perpendicular. Apart from mountain trails, there are probably few, if any, traveled roads in this country having such a grade. The possibilities of the automobile as a hill climber have been most surprisingly demonstrated in its ability, and remarkable climbs up wooden inclines have also been made to mount long flights of stairs. There is no definite data available as to the grade percentages of the hills you mention. Fort Lee Hill rises something like 300 feet in a little more than half a mile, or putting it roughly, one in nine, which gives it an average grade of 10 to 11 per cent. Eagle Rock is considered to range from about 6 to 12 or 13 per cent., and the same is true of Jacob's Ladder, except that in the latter case, the surface is nothing like as good, which is an important difference.

Trouble From Unusual Location of Carbureter.

Editor THE AUTOMOBILE:

[586.]—I would like your opinion on the following: I have a light touring car containing a 16-horsepower, double-opposed motor. Bought it new August 27, 1906, and have always had more or less trouble with front cylinder; it has not as much power as rear cylinder, does not seem to burn the mixture thoroughly, emits black smoke, and soots spark plug so that it is necessary to clean it every three or four miles since it has been cold weather—it was not so bad during warm weather. The intake valves are on opposite sides of motor. It is about two feet from carbureter to front intake valve, where intake pipe divides within about six inches of front intake valve. The intake piping for rear cylinder extends from this division along side of motor and around the rear end to intake on opposite side. The rear intake pipe is about four feet long from division, as against six inches for front intake pipe.

The rear cylinder apparently works perfectly, and always has. So far as I can see the valves of front cylinder work and fit perfectly. I have transferred spark plug and wiring and coil from rear cylinder to front one, with no better results.

Do you think it is possible to get the proper mixture to both cylinders with such a difference in the length of intake pipes? It is my opinion that the front cylinder gets too rich a mixture, and that if I change the carbureter to that end, the rear one will get too weak a mixture. I am going to make the experiment as soon as weather will permit.

C. A. KINSEY.

Adrian, Minn.

Such an excessive difference in the distance of the two inlet valves from the carbureter, *i.e.*, six inches to the forward cylinder and four feet to the rear cylinder, would appear to be something that no amount of adjustment of the carbureter itself could possibly compensate for, and there seems to be little question but that it is responsible for the trouble you have experienced. With few, if any exceptions, it is customary with designers to make the inlet manifold of such a shape that the distance from the carbureter to each of the inlet valves will be approximately, if not exactly, equal, whether the engine have two or four cylinders. It is evident that if the carbureter be adjusted so as to produce a good mixture for the forward cylinder, the rear one will be starved, and if the latter be the one in view when making the adjustment the forward one will be choked, which seems to be the case. At least one well-known designer attempted to overcome this by the use of two independent carbureters placed directly at the inlet valves of the two-cylinder engine, but it was found difficult to synchronize them, and, after two years' use, the usual method of placing the carbureter equidistant between the two valves was adopted. We should be pleased to hear the outcome of your experiments.

Is Skidding Lessened by a Front Drive?

Editor THE AUTOMOBILE:

[587.]—Would a car driven through its front wheels be as liable to skid as one of ordinary design, both being operated under like circumstances?

Your articles on "The Question of Sideslip" in the issue of "The Automobile" for November 15 and 22 discussed the matter with regard to machines of ordinary construction, but I would like to know how these same forces would affect a car built on the plan of Christie's racer.

H. W. HAMMOND.

Ludington, Mich.

While there is no definite data available on the subject, we think it has been noticed that at ordinary speeds cars using a front drive are not given to skidding to the same extent as those of the ordinary type, when, by skidding, a slewing round of the rear half of the car in turning corners is meant. If, on the other hand, by skidding is meant that manifestation of centrifugal force that causes a whole car to travel sidewise, or, in other words, to attempt to continue traveling in the same direction when a curve is rounded at excessive speed, it is at least questionable whether the fact that the front or rear wheels are driven has any bearing on the matter. It is thought by those who have given the subject any attention that the matter of braking has a great deal to do with it; that if the front and rear wheels were retarded simultaneously the tendency to skid would be minimized. We have never seen the question treated at any length solely from the point of which pair of wheels was driven; the differential is an important factor.

Combination Air and Water Cooling of Motors.

Editor THE AUTOMOBILE:

[588.]—Is there now on the market a combination air and water-cooled motor? Kindly give objections to it, and also the advantages, if any. Could it be perfected, and is it worth while to attempt it?

A SUBSCRIBER.

Your idea amounts substantially to a simplification of the present systems of water cooling, since even with water cooling systems the real cooling is done by air, and the water simply serves as a means of conveying the heat units from the cylinder walls to the radiating surfaces. You eliminate, of course, the piping, the pump, etc., but largely offset these advantages by reducing the cooling surface unless you use an extraordinary large jacket. Also, the idea is not new, since the Dufaux cars, made in Switzerland, were made in one or two models of a year or so ago with small, "ear-like" honeycomb radiators built directly upon the cylinder jackets.

ANOTHER SOLUTION OF "550," WITH MANY "IFS."

Editor THE AUTOMOBILE:

[589.]—Relative to Letter No. 550, in the January 31 issue, by "Subscriber, Chicago, Ill.," I have no doubt the machine referred to has been made by the Maxwell-Briscoe Co., Tarrytown, N. Y. If "Subscriber" is absolutely certain there is a positive contact on each pole of the commutator consecutively at the same point on the perimeter of the flywheel, and that the brushes have an equal pressure on the cam—no guessing—that the air adjustment gives all the air necessary; that the needle valve is not open two and one-half turns, when one-quarter turn is all he needs to run the engine, that the carbureter is not half full of mud and water; that he has taken the spark plugs supplied by the factory and thrown them into the nearest river, or placed them in the furnace to help heat his home; that the plugs he now uses are not worse than the others—are perfectly clean, not smeared with oil or carbon; that they fire on the points, not in the chamber; that his secondary wires do not short-circuit on the frame or hood; that his commutator wires are not broken and make an occasional contact as vibration impels them; that he has gasoline in his gas tank, not in the condenser; that all his connections are tight; that his valve plugs, relief cocks, spark plugs, etc., do not lose all his compressed gas on both or one cylinder; that there are no holes in his inlet pipe, or a pound of waste on the valve seats, causing the valves to leak or remain open; that his valve springs are not weak or broken; that the pins holding the cams in position on the camshaft are not broken or loosened and dropped out, causing the valves not to open and close at the right moment; that the valve stems are of equal length with regard to their release by the tappet rods; *i.e.*, that the valves of one cylinder do not open sooner and remain open longer than those of the opposing cylinder. Assuming the above to be O. K., I would say look to your coil; you will find a stiff or rigid armature on one unit, a flexible armature on the other, possibly the contact points burned away on one or both. It is like throwing good money after bad to send to the factory for two armatures of equal flexibility. They don't know the difference between "hard" and "soft," or "rigid" and "flexible." Take the coil and do with it as you did with the plugs; it will be the cheapest method in the end. I have had success with the Spiltdorf latest make, and also the Connecticut coils. I am not biased in favor of or against any of the above coils.

F. J. P. FITZGERALD.

Englewood, N. J.

IN SUPPORT OF THE HIGH-POWERED RUNABOUT.

Editor THE AUTOMOBILE:

[590.]—Unlike Demarest Lloyd, of Cambridge, Mass., I don't want to get mixed up in a controversy between two magazines covering the same field, and, on account of that position, more or less antagonistic. Over ten years' experience in newspaper work has, I think, taught me the futility of such contests. It is so in the newspaper field, and I'm sure Mr. Lloyd will find it no better in the realm of the magazine. I do, however, want to say my little say about this cry of "wolf" about the "high-powered runabout." What is really the matter with the runabout as made and sold by the manufacturer of almost every representative automobile to-day? It is not because they are in themselves infractions of rules of the road, rules of society, rules of symmetry, or any other which does not apply to any other high-powered machine. It cannot be that the only fault found with it is its excessive speed, for what car of note to-day is not capable of fracturing every speed law devised by legislatures? I have before me a small folder received from a manufacturer yesterday. It describes a 1907 product, and says "seats five, powerful, capable of from 21-2 to 60 miles on the high gear per hour." This with a regular body. Now, by converting this same chassis into one of the much-

despised (?) runabouts probably five more miles an hour could be secured, but is that so much greater a crime than the bare 60 miles, which in itself is three times the legal limit of speed in almost, if not all, the States? It is a question, if taking vibration, traction at the rear wheels, and smoothness in riding, whether the temptation to run 50 to 60 miles an hour, with five passengers, is not greater than to go a few miles faster with only "two up?" I think so.

For touring purposes, where only two people are concerned, as is the fact in my case and hundreds of others, there is nothing better than the runabout of high power. For then hills of the steepest nature and roads of the deepest sand can be negotiated at an unvarying speed. Whoever has tried to carry the necessary articles for the bare necessities on a trip in the tonneau and then used the "beetle-back" knows the difference. Those persons who are legitimate lovers of the sport, and not simply "speed fiends," need and desire just such a car, and because it looks like a racing car, should not outlaw it from the auto ranks. The great fault is not in the high power of the runabout any more than the high power of the touring car. It has its place—just as has the touring car, the limousine, the electric, and the commercial vehicle.

Middletown, Pa.

JOHN W. FEW, JR.

A METHOD OF COMPUTING COMPRESSION.

Editor THE AUTOMOBILE:

[591.]—Referring to letter No. 490, in issue of December 6, on "Compression Space and Compression Pressure," I herewith give my method of computing the same, since I note that you ask for the opinion of readers on different subjects.

First, let the compression required in pounds to the square inch, gage, equal CP. Second, assume the temperature of the cylinder volume in operation, or take the computed temperature of same, to equal Vt, when compressing. Third, regard as constants the range of 460 from vacuum to OF and the 0.002 increase in volume of pressure for each degree rise in temperature—14.7 pounds to the square inch equalling 1 atmosphere. Then,

x equals $(Vt \text{ plus } 460 \text{ times } 0.002 \text{ times } 14.7 \text{ minus } 14.7)$ equals x equals increase in pressure;

CP minus x equals y and y divided by 14.7 equals total volume to one volume of compression space,

v equals total volume. V equals volume compressed.

Example:

Vt equals 840 plus 450 equals 1300. X 0.002 equals 2.5 times 14.7 equals 38.22 minus 14.7 equals 23.52.

23.52 equals x , CP equals 65 pounds minus 23.52 equals 41.48 equals y equals compression pressure without heat of cylinder volume, y divided by 14.7 equals 2.822 equals v to 1 volume;

Therefore total volume equals 28.22 to compressed volume of 10.00

Compression pressure equals $\frac{v}{V} \times X \text{ times } 14.7$, not including heat, or

A equals atmospheres and A equals 1 atmosphere equals 14.7

P equals $\frac{a \ v}{v}$ and A equals $\frac{v}{V}$ and $\frac{v}{A}$ equals V as before

v equals total volume and V equals compressed volume.

Sixty-five pounds compression when the engine is in operation—or at time of explosion—equals a compression pressure of 41.48 pounds compression when not in operation, which is the basis of calculated compression space to obtain an equal compressure pressure of 65 pounds. I hope this is not too much in the way of figures on the compression problem.

Chicago, Ill.

R. C. MATLAC.

TWO-CYCLE MOTORS AND DAIMLER'S SUCCESS.

Editor THE AUTOMOBILE:

[592.]—C. P. Malcolm, in your February 7 issue, while commenting upon the troubles abounding in two-cycle motors as a type, puts forth the claim that the original Daimler motor was sent to this country to revolutionize the gas engine industry. Mr. Malcolm says: "The Daimler people found out that without real merit no amount of business ability, all of the push, all the pull that could be brought into use would not build up a reputation; would not make a great and permanent business success of a mechanical mediocrity of achievement." If Mr. Malcolm had been talking about two-cycle motors instead of the Daimler, then it would be possible to take some stock in his statement, but no amount of ill-conceived talk will ever be equal to the task of reducing the value of the Daimler achievement.

True, Daimler advanced, but the original Daimler motor was an advance, and the success of the Daimler project is more plain than Mr. Malcolm's failure to make two-cycle motors mote.

Whether or not the two-cycle motor will ultimately grow up and be somebody—so to speak—is quite another matter, a question, in fact, that will probably be settled along lines suggested by Mr.

Lougheed, i.e., "Improvements are not bound up in mere adaptations of present constructions and ill-advised applications."

In any case, no amount of effort to erase the work of Daimler will make the two-cycle project any more a success than it is. It is not the purpose here to decry the two-cycle motor; indeed, the writer is trying to make a success of it; but if failure results, it will not be the writer's plan to try to pull the Daimler effort down to the level of a two-cycle failure.

THOS. J. FAY.

Brooklyn, N. Y.

AUTOS A REASON FOR RIVER IMPROVEMENT.

Editor THE AUTOMOBILE:

[593.]—We have data to show that a larger number of autos in proportion to the population are used in and around Stockton than in any part of the West, and possibly than in any part of the United States where agriculture is the chief industry of the people. This is the natural result, for the great San Joaquin Valley, which at this point is over 40 miles wide, and stretches for over 300 miles southward, is so perfectly level that the automobile has become the vehicle of daily use for extensive journeys and for the expedition of business as well as for pleasure. In this county alone are over 1,200 miles of rural roadways which are daily traversed during seasonable weather by automobiles, many of which are owned by the prosperous farmers.

I mention this fact as introductory to the subject of developing this valley by an improvement of the San Joaquin river, which is the great natural highway of traffic that permits the producers of this region to cheaply reach the markets of the world. Any movement therefore to advance this development is directly in the interests of the automobile trade, and I call your attention to the illustrations and texts of the memorial adopted by the Stockton Chamber of Commerce, asking Congress for a survey of the river, with a view to its ultimate improvement.

Stockton, Cal.

J. M. EDDY,
Secretary, Chamber of Commerce.

A CASE EXACTLY IN POINT.

Editor THE AUTOMOBILE:

[594.]—Letter No. 550, signed "A Subscriber, Chicago, Ill.," in the issue of January 31, excites my sympathy, because I have had exactly the same trouble, and have cured it completely. I had a double-opposed cylinder runabout, which performed the exact tricks described by the correspondent mentioned above. I made up my mind that the trouble was either in the mixture or ignition, and doctored both as follows:

I got a larger auxiliary air valve for the carbureter (twice the opening of the old one), and I cut out just one-third of the voltage of my batteries by connecting them in multiple. One or the other of the improvements, or both, cured my trouble completely. My runabout has been about 1,500 miles since the change, without a stop or trick, while before it never ran 100 miles without trouble. I advise "Subscriber" to try dry batteries—starting with four ordinary Columbias, then trying five, which ought to be all right. After he determines the best voltage he can work his storage battery accordingly.

If this does not cure his trouble, I advise him to get the air through the carbureter quicker, either by changing carbureters, or by getting a large air valve made to fit his carbureter.

New York City.

STEADY READER.

A POINTER FOR "SUBSCRIBER"—No. 550.

Editor THE AUTOMOBILE:

[595.]—I have read over the letter of "Subscriber," No. 550, which is headed "A Trouble With Peculiar Symptoms," and also your answer thereto, and the only thing that strikes me as having been omitted from the latter is the fact that the cylinders of the engine on his car may have become carbonized, or the flywheel may have worked a bit loose, which would account for the pounding. I think if he will look over these two points and also reduce the range of movement of the timer, as you suggest, that he will not have any further difficulty from this cause.

Boston, Mass.

D. F. M.

THE SIMPLEST REMEDY FOR KNOCKING.

Editor THE AUTOMOBILE:

[596.]—I would like to venture an opinion in regard to letter No. 550, in which the writer complains of knocking when spark is even slightly advanced under load. The symptoms sound to me like a deposit of carbon in the cylinders. At least, the same troubles developed in a car of mine, and were cured by cleaning out the cylinders. This explanation sounds ridiculously simple, perhaps, but, in view of my almost identical experience and that of others, it seems plausible.

Cambridge, Mass.

PLAUSIBLE.

POWERFUL SIX-CYLINDER NATIONAL RUNABOUT WHOSE 75-HORSEPOWER ENGINE SHOULD MAKE IT A SPEED WONDER.

PROBABLY there is nothing that typifies speed and power so forcibly as the modern high-powered runabout, and this is very much heightened when the power plant is of the six-cylinder type, as is the case with the National 75-horsepower runabout illustrated at the head of this page, and which will form one of the strongest numbers in the National line of cars for the coming season. The colors in which the representative of this type exhibited at the recent Chicago show was finished made an attraction of it that the visitor could not overlook, regardless of whether he happened to take any particular interest in that type of vehicle or not. The body and fenders were painted an apple green with white striping, while the chassis was painted a bright red, set off in the same manner, the bucket seats being upholstered in leather of the same brilliant hue as the chassis. It was equipped with 36 by 4½ wheels and tires, the latter being Diamond flat treads, and was indeed an impressive example of the extent to which manufacturers have lent ear to the popular demand for this semi-racing type of two-seated vehicles.

In striking contrast with it was a nine-seated limousine body on the same type of six-cylinder chassis, so that so far as its power plant was concerned this car was a counterpart of the

racy-looking monster. Apart from this, however, the keynote of its construction and finish were to be found in everything that lent themselves to the comfort and luxury of the occupants. The body of this car was painted black, with the interior finished in mahogany and upholstered in black goatskin. The chassis was also painted black, giving the whole that appearance of staid dignity and respectability that is one of the chief attributes of this most luxurious of cars. Its seating capacity of nine adults is something quite unusual and on that account was the subject of not a little comment. Beside the two bucket seats in front, there is accommodation for seven people in the enclosed portion of the body. It is equipped with two revolving chairs, in addition to the regular limousine seats, and its fittings include besides the usual toilet articles, a buffet, ice chest, writing table, mirrors and the like. It is lighted by electricity and communication is had with the driver through a speaking tube.

Another six-cylinder of the National line is the Model L touring car. The chassis and motive power are practically the same as used in the above-mentioned runabout and limousine, the body being very capacious and provided with extra seats in the tonneau.

The National four-cylinder cars embrace the National Model 11, 50 horsepower, and Model F, 40 horsepower, in limousine, touring car and runabout types, and all are the products of the National Motor Vehicle Company, of Indianapolis, Ind., and bear the distinguishing mark of the round radiator. With all these models a very complete equipment is included, comprising searchlights, lamps, tools, aprons, horn, etc.

SIX-CYLINDER NATIONAL LIMOUSINE THAT WILL SEAT NINE ADULT PASSENGERS

PREFERS TAR TO OIL AS A ROAD SURFACER

BY way of experiment, State Highway Commissioner James H. Macdonald of Connecticut has been treating a stretch of highway near Hartford with a coating of tar as a top dressing, and as the result appears to have been satisfactory the Commissioner in his recent report expresses some decided views upon the comparative merits of tar and crude oil treatments of highway surfaces, to the advantage of the former, at the same time admitting that the present method of spreading the tar is crude and must be perfected to obtain the desired lasting results. Mr. Macdonald says:

"The treatment of a highway with a tar compound is, of course, primarily to make upon its surface a coating which will withstand traffic whether of teams or automobiles. To succeed perfectly in this matter the method of applying the tar must be improved upon. At present it is primitive. A barrel or so of tar is heated in a jacketed boiler and run out upon the surface of the highway from a two-inch pipe, the flow being controlled by a valve. When once on the surface of the highway the hot tar is spread by means of brooms or a squeegee, the distribution being uneven as a result. Now, some means must be devised of getting this tar or tar product upon the surface of the road in an even coating, and some invention to this end must be discovered. A second thing which must be regarded is the weather. The tar must be applied when the weather is dry and hot, the dryer and hotter the better, if the surface of the road thus treated is to stand against the force of the automobile. The experience of the past warrants the belief that the method of applying tar will be so perfected that the treatment will prove successful. The end is, of course, to secure a road surface that will withstand all the strain of traffic, and to this end experiments with crude oil or some tar product are being made. There are advocates of both fluids and it will take time to tell which is the better.

"Heat is essential in the application of either tar or oil, heat being necessary to bring out the efficiency of the valuable elements. From my experience with tar I should say that the degree of heat necessary in applying it successfully is about the same as that needed in repairing concrete sidewalks. The road surface should be dry and the application made during a prolonged dry season at that. The tar should be heated to about 300 degrees and should be applied evenly, so as to form a complete veil over the surface of the road. The ordinary tar as produced as a by-product of the gas house is not calculated for the work, being too thin and containing elements not desirable for the work. The compound used should be thicker, certain volatile elements having been driven out of it. After the compound has been applied it should be followed by a coating of fresh stone no larger than will run through a half-inch screen.

The stone should be thoroughly clean and free from dust and should also be heated when put upon the tar compound. The road, for that matter, should have been cleared of dust before the application of the tar. After the stone has been applied the road should be rolled and then kept free from traffic until thoroughly cool, in order that the coating upon the surface may not be torn up by any vehicle.

"The use of crude oil has been more extensive, probably, than the use of the tar products, but in some respects it must be treated in a different manner. It is desired, however, to attain the same end, that of forming an elastic, dust-proof cushion upon the surface of the road. The use of crude oil is attended with less expense than tar, but it is just as desirable to apply it hot and when the road is dry. If the oil is heated it penetrates the roadbed more easily, but it is not so necessary that the surface of the road shall be clear of dust. There is very little wearing ability inherent in oil, and the dust or detritus absorbed into the oil combines to form the wearing surface of the road. The oil repels moisture better than tar. Water can be mixed to a certain extent with tar, but it is hard work to mix oil with water. On account of its lack of body oil should be applied two or three times at intervals of a month or so. Oil has been used considerably in the West on gravel roads, where it has been found to combine with the gravel so as to form a wearing surface of considerable durability. Its use should not be attempted on roads in which loam or clay predominate, and in all cases the surface of the road should be dry."

TREASURY SURPLUS FOR GOOD ROADS.

WASHINGTON, D. C., Feb. 18.—A unique good roads bill has been introduced in Congress by Representative John Sharp Williams of Mississippi. Its object is to distribute the surplus in the Treasury of the United States to the several States and Territories for the sole purpose of improving the roads therein.

The bill provides in effect that it shall be the duty of the Secretary of the Treasury at the end of each fiscal year to take an account of all the funds in the Treasury and after deducting from said sum the amounts required by law to be kept in the Treasury, the remainder, if any, shall be declared a surplus. The Secretary of the Treasury must then immediately provide for the distribution of this surplus, not exceeding \$25,000,000 annually during the continuance of the proposed law, on a per capita basis to the States and Territories, to be computed for the last general census, and shall prorate the same accordingly, for the sole purpose of improving the postal roads in said States and Territories, under such rules and regulations as the States and Territories may provide.

IMPROVING A ROAD IN SANTA CLARA COUNTY, CALIFORNIA, WHERE GRAVEL BEDS PREDOMINATE.

A. A. A. PROPOSES FEDERAL AUTOMOBILE BILL

AT the first meeting of the Executive Committee of the American Automobile Association, held Thursday, February 14, in New York City, Charles Thaddeus Terry, chairman of the Legislative Board, presented the proposed A. A. A. federal automobile bill, which will be introduced in Congress before the close of the present session. Recognizing that there exists throughout the country a general demand for uniform automobile legislation, President William H. Hotchkiss lost no time in appointing a legislative board, and Chairman Terry prepared at once, after consulting with his associates and others, the proposed bill, which unquestionably will serve to get the subject before those vitally interested, even though it may require some time to transform the measure into a law. It will be introduced before the close of the present session of Congress and again at the new session after March 4 if lack of time prevents its early consideration. The State bodies throughout the country will be called upon to lend all possible aid in calling the attention of their congressmen to the bill.

Annual A. A. A. Tour May Start in West.

Chairman F. B. Hower, of the Touring Board, was the only national chairman unable to be present at the meeting, he being at the time in California. Nevertheless, the Executive Committee voted that in its opinion the annual A. A. A. tour for the Glidden and other trophies should start from Chicago or some other Western city. This, however, is contingent upon the guaranteeing of a sufficient number of entries by the Westerners. It has been suggested that there might be a Western and Eastern division which would meet somewhere in Pennsylvania and continue to Washington. From that city there might be a supplemental tour through Virginia, the Shenandoah Valley, the

Jamestown Exposition being a possible destination. The Touring Board will at once get to work on rules, for it is desired that the conditions be enumerated at the earliest possible moment.

Racing Board Membership to Be Increased.

In line with the policy of the administration in making the various boards representative of the entire country, the Racing Board will be increased in numbers, and Chairman Jefferson DeMont Thompson at once will prepare the added names and submit them to President Hotchkiss for approval. Members will be named for all parts of the country in which racing events are likely to take place, including the Pacific and Western States, Florida, and Several Eastern States. It may become necessary to designate executive committees for the several boards.

Good Roads Board Wants National Aid in Road Building.

Chairman Robert P. Hooper, of the Good Roads Board, reported that his board will be completed in the near future, when a session will be held, at which the matter of government aid in road-building will receive attention, it being his idea, as well as that of several of his associates, that something along this line can be accomplished in view of the present universal agitation for the construction of improved highways.

Present at the Executive Committee meeting were: President, W. H. Hotchkiss; first vice-president, Lewis R. Speare; Jefferson DeMont Thompson; treasurer, George E. Farrington; Sidney S. Gorham, and A. G. Batchelder. A. R. Pardington attended as representing William K. Vanderbilt, Jr., who is at present in Europe. Robert P. Hooper, chairman Good Roads Board, and Charles Thaddeus Terry, chairman Legislative Board, were present upon invitation.

AUTO'S PRACTICAL VALUE THOROUGHLY DEMONSTRATED

WASHINGTON, D. C., Feb. 18.—“In five years the manufacture of automobiles in the United States has grown from an industry so unimportant that it was not reported separately at the census of 1900 to one with products valued at \$26,645,064 at the census of 1905, which covered the calendar year 1904,” says George E. Oller, in an elaborate report prepared for the Census Bureau. The author says this remarkable growth is not, like that of the bicycle, based on a fad, and so liable to as sudden a decline. Unlike the bicycle, the automobile is not essentially a new vehicle, but merely a carriage or truck with a new means of propulsion, possessing many advantages over a vehicle drawn by horses. As a means of amusement its popularity may fluctuate or decline, but its practical value has been so thoroughly demonstrated that its use will doubtless become more general each succeeding year, until it is displaced by some vehicle as much its superior as the automobile is the superior of the horse and wagon.

Though not yet perfected, says the report, the automobile has become at least reliable. Models and parts are being standardized, thus rendering it possible to replace broken or worn out parts without delay. In the United States many express and transfer companies, department stores and fire departments have abandoned the horse-drawn vehicle for the automobile. In New Mexico it has supplanted the stage coach between Roswell and Torrance, a distance of 101 miles. It has worked a revolution in Nevada, where the means of local transportation have heretofore been confined to the mule. Liverymen acknowledge the passing of the horse by operating automobiles in connection

with their stables. In many of the larger cities the automobile has been introduced for public transportation. Although it is as yet unsuited for general transportation in the field, yet the utility and advisability of the self-propelled vehicle for military purposes have been amply demonstrated. In Germany armored automobiles are being constructed for use in the army.

In the United States the use of automobiles will be limited only by their cost and the condition of the highways. The cost is gradually becoming less and the automobile itself is already felt as a factor in the movement for good roads.

The report gives a detailed historical and descriptive sketch of the automobile, which is entirely familiar to most automobile users. The report says the relatively small increase in number of establishments is due to the fact that the 57 reported in 1900 were engaged largely in experimental work, with little capital invested, and employing few workmen. Growth has been along the line of extending the capacity of the old plant, or abandoning them for new and much larger ones, rather than in increasing the number of establishments.

In 1904 the manufacture of automobiles was carried on by 121 concerns in seventeen States, while in 1900 thirteen States had automobile factories. At the census of 1904 Michigan, with 22 establishments, ranked first; New York stood second, with 21, and Ohio third, with 14. Massachusetts, with 11 establishments; Illinois and Indiana, with 8 each; Connecticut, with 7; California, Pennsylvania and Wisconsin, with 6 each, and New Jersey, with 5, followed in the order named.

PROPOSED PENNSY LAW HAS GOOD POINTS.

PHILADELPHIA, Feb. 18.—Many prominent local automobilists are in favor of the proposed Woodward bill, now before the State Legislature. One great point in its favor is the elimination of all local automobile legislation, Section 13 of the proposed new law killing all city, town and borough ordinances governing the operation of motor vehicles. Section 11 would sound the death-knell of the road hog who takes a fiendish delight in blocking an automobile on a narrow road; it would cost him \$10 for the first indulgence and \$25 for a second and subsequent, or 10 and 20 days respectively in jail. There are several other good points on the bill, and it is admittedly an improvement over the present law.

Motorcyclists, however, are not so liberal in their praise of the proposed new law. It would continue the present legal status of a motorcycle as an automobile, with the single exception that a red tail lamp need not be carried. This the riders of the motorcycle claim as an unjust discrimination, and the Federation of American Motorcyclists will send a delegation to Harrisburg to ask that some modification of the measure be made that will relieve them of the necessity of carrying two tags and wearing a 2 1-2-inch breast-plate bearing the legend "Pennsylvania Licensed Driver."

MINNESOTA'S PROPOSED NEW LAW.

ST. PAUL, MINN., Feb. 18.—A complete new automobile law for Minnesota is proposed in a bill introduced recently in the Minnesota legislature. It establishes a maximum speed of eighteen miles for country roads and for all highways not otherwise specified in the bill. For cities and for dangerous pieces of roadway, as before school houses and churches, and at cross roads, the speed is limited to eight miles. Cities and towns are also given full authority to pass local ordinances and regulations.

The proposed law provides that certificates shall be issued by the Secretary of State upon payment of a license fee of \$2. No provision is made for establishing the identity of a car, as to its county or city, however, and some automobile owners of Minneapolis and St. Paul have already protested. The numbering system in the two adjoining cities is badly snarled, as the result of conflicting laws passed within the last two years, and it is expected that an attempt will be made to straighten the tangle, through another law, to be offered later.

INDIANA LAW TO REMAIN SAME.

INDIANAPOLIS, IND., Feb. 18.—It has been practically decided by the Indiana Legislature that no legislation affecting automobiles will be enacted at this session. This was demonstrated a few days ago when, without debate, all automobile bills except one were postponed indefinitely on the recommendation of the Roads Committee of the House of Representatives. A decision that the law enacted two years ago covers the ground in a satisfactory manner is given as a reason for no further legislation.

CONFERENCE NEW YORK STATE AUTOISTS.

ALBANY, N. Y., Feb. 19.—The Legislative Committee of the New York State Automobile Association, with President Oliver A. Quayle presiding, held a conference to-day at which were discussed the various automobile bills that have been introduced at the present session of the State legislature. The situation was thoroughly discussed and a policy for future action decided upon. Delegates were present from nearly a score of clubs.

COULD ALSO DISCUSS UNIFORM AUTO LAW.

ALBANY, N. Y., Feb. 18.—Assemblyman Edwin A. Merritt has introduced a bill calling for a convention of delegates from the different States for the purpose of discussing uniform laws for the control of public service corporations. It has been suggested that the measure can be amended so as to include uniform automobile legislation.

NEW CHAUFFEURS' LEAGUE IN KENTUCKY.

LOUISVILLE, KY., Feb. 18.—The chauffeurs of this town have banded themselves together by the formation of the Chauffeurs' League of Louisville. A constitution and by-laws have been adopted and the following officers elected: President, James B. South; first vice-president, Chas. C. Morat; second vice-president, James Reister; secretary, W. C. Baker; treasurer, Roscoe Hogle. The most important feature of the League will be the College of Automobile Engineering, of which the officers of the League are directors. By means of demonstration and lectures it is expected to considerably raise the mechanical ability and professional status of the chauffeurs. The League protests against the whim of automobile owners in making their chauffeurs wear a uniform. In consequence of the increase in stone throwing at autos by rowdies the league has offered a reward for the arrest and conviction of offenders.

THIS AUTO IS INDUSTRIOUSLY VERSATILE.

ELKHORN, WIS., Feb. 11.—A Walworth county farmer who last summer caught the auto fever and bought a machine has it stored to-day where very few people would find it when out of motion. It is perched up somewhere near the ridge pole of the barn. It is resting on beams and is there stoutly bolted. All of the wheels have been removed, but on one end of the rear axle is a big flywheel and on the other a driver. Below on the barn floor something like a dozen different grinding, sawing, and chopping machines are belted at different times. The auto that is up in the air in winter quarters works every day at one stunt or another and has never laid off for repairs. The engine is worked on the two lower speeds, so that the machine is not wearing itself out by its unusual line of winter work.

WHERE AUTO IS POPULAR WITH THE FARMER.

GORDON, NEB., Feb. 15.—That the automobile is cutting considerable figure in farming matters nowadays is evidenced by the photograph taken last fall during the potato harvest. The party in the car is on an inspection tour over one of the largest potato patches in the great West. It is located near Gordon, on the Black Hills line of the Chicago and Northwestern Railroad, and in Sheridan county. This farm is so extensive that it requires all of the most modern potato raising machinery to handle the crop. A good many Sioux Indians are employed.

Some of the land agents who are in the new farming countries of the West and Northwest say that the automobile has made more rapid progress into the domain and the uses of the soil tillers than in the localities near the large cities of the Middle West. One feature of their adoption by farmers is the great variety of uses to which the cars and their power is put. In making fast time over the big ranches the automobile has laid the fast-flying broncho in the shade.

INSPECTING A NEBRASKA POTATO FARM BY AUTOMOBILE.

AUTO CLUBS PREPARE FOR SPRING WORK

Jersey Autoists Alive to Legislative Necessities.

NEWARK, N. J., Feb. 18.—At its meeting last week the New Jersey Automobile and Motor Club gave consideration to important legislative matters that have arisen in this State within the past six months. The sense of the meeting was that the present law provides entirely too many loopholes for motorists who are reckless and who do not propose to obey the law if they can avoid doing so. One of the most important of the resolutions passed was in favor of having all license pads issued by the State, thus attaining the uniformity of design that has been such a successful feature of the Pennsylvania law.

Another resolution of vast importance was that which calls for the carrying of lights at nights by all vehicles, whether horse-drawn or propelled by motors. There has already been introduced into the legislature a bill calling for the carrying of two lights on all vehicles.

The New Jersey Automobile Club has decided not to support this, however, for the reason that in many cases it would work a hardship to owners of horse vehicles, although it is practically a necessity in the case of automobiles. The motor club's resolution calls for only one light. It was stipulated that this provision go as an amendment to the general road laws and not to the Frelinghuysen automobile act.

Other resolutions having to do with the increasing of the force of motor vehicle inspectors with power to arrest without war-

rant, and to require motorists to show licenses; the throwing of glass and nails upon highways, and the establishment of a permanent legal committee by the club were passed, as was a resolution to the effect that all automobilists who are regularly registered in their native States shall have the right, by application to the Federal Government, to a certificate that will give them the right to pass through any State in the Union.

Aero Club Banquet at Hotel St. Regis, March 14.

NEW YORK CITY, Feb. 18.—The first banquet of the Aero Club of America will be held at the Hotel St. Regis, March 14, and the quick response to the suggestion makes it probable that the seating capacity of 150 will be severely taxed. It is among the probabilities that the Wright Brothers will be guests of the occasion, with representatives of the St. Louis Aero Club.

F. S. Lahm, J. C. McCoy and A. R. Hawley have been selected to represent America in the Gordon Bennett contest at St. Louis in October next. Three alternates will be announced later. Capt. Charles deF. Chandler, of the Telegraphic Division of the Signal Corps, U. S. A., has charge of the arrangements for the Washington's Birthday balloon ascension, to take place at Washington, D. C., on Friday of this week. The club's headquarters will be at the New Willard Hotel.

Quaker Yorkites Will Entertain A. A. A. Tourists.

YORK, PA., Feb. 18.—Two events of more than ordinary interest—the proposed southern tour of the American Automobile Association and the big endurance run which will have York as one of its stopping places—have served to inspire the local autoists with new enthusiasm. The first event, which is by far the most important of the two, will be given a welcome reception in this city should the A. A. A. committee decide to send it South by the famous Gettysburg pike route. It is certain that in giving this route consideration no better opportunity could be afforded the Glidden tourists of viewing, not only one of the most picturesque stretches of landscape in the country, but one that is replete with historical mementos of the great civil conflict of 1861-65. The tour would also add greatly to the movement for improvement which is at the present time being strongly agitated.

The York County Automobile Association at its last meeting took up the A. A. A. tour subject, and, with general accord, it was decided to give the tourists a royal form of entertainment in the event of the route being set in this direction. "Globe Trotter" Glidden, in his recent tour through this part of the country, was much impressed with the scenery. The roads are not the best that could be had, in his estimation, but they are not bad either. In Glidden's terms, "The roads through the Keystone State are fair for touring."

The endurance run, which will be held

April 8 and 9, starting from Harrisburg and making this city the first general stop, will be participated in by quite a few Yorkers. The run will extend through Lebanon, Marietta, Columbia, Wrightsville, York, Gettysburg, Waynesburg, Chambersburg, Carlisle, Mechanicsburg, and back to Harrisburg. Two silver cups will be given to the successful contestants.

Activities of the Quaker City Motor Club.

PHILADELPHIA, Feb. 18.—Local automobilists are wondering whether there is an African in the wood-pile in the action of the board of governors of the Quaker City Motor Club, last week, when a committee consisting of Nathaniel Hathaway, George H. Smith and G. Douglas Bartlett was appointed "to get in touch with the automobile clubs of the State, with a view of forming a State organization." The fact that the action mentioned followed the election of President Charles J. Swain as the club's representative on the Touring Board of the American Automobile Association is said to have some significance. Many of the members of the Quaker City Club also belong to the Automobile Club of Philadelphia, which is affiliated with the Pennsylvania Motor Federation.

Said one prominent P. M. F. man in discussing the matter: "It seems like an entering wedge for a tentative compromise.

AN A. C. OF CALIFORNIA CLUB RUN AT THE HOTEL DEL MONTE. Monterey, Cal., is one of the most popular resorts on the Pacific Coast, and a favorite terminal for the tours of automobilists in the vicinity of San Francisco.

having for its ultimate object a thorough reorganization of all the automobilists of the State under A. A. A. auspices. I, for one, would welcome such an outcome, for while the Federation is doing excellent work, I believe that it could do even better had it the backing of the national body. Such an arrangement could be framed up without much trouble, and any points of friction could be easily neutralized by an application of a little oil of common sense. I do not believe in dividing forces in sight of the enemy; every owner of a motor car in the State of Pennsylvania should belong to a single organization working, first, for the betterment of conditions in our own State; and second, for the passage of national automobile laws which shall improve conditions throughout the country. This latter benefit cannot be obtained through the medium of a State body."

Among other business transacted by the board at the meeting was the naming of the Contest Committee, consisting of W. Wayne Davis, C. A. Woolson, E. H. Lewis, T. B. Creamer, G. Hilton Gantert and Richard A. Sellers, with the indefatigable E. C. Johnson as chairman. The board later sanctioned the committee's project of holding a monster hill climb on Memorial Day. The membership committee, to whose conscientious work much of the present success of the club is due, was reappointed *in toto*. It is made up of C. A. Woolson, H. B. Lasher, J. A. Wister, A. T. Stewart and W. Wayne Davis.

President Swain and seven of his confrères leave to-night for the Cleveland show, and will visit Akron's tire factories before their return.

Tacoma A. C. Holds Its Annual Election.

TACOMA, WASH., Feb. 18.—At the annual meeting of the Tacoma Automobile Club a complete new set of officers was elected, and one which assures that the automobile interests here will be well guarded. The new officers are: President, Chester Thorne; vice-president, Richard Vaeth; secretary, H. H. Gove; treasurer, Fordyce Taber; trustees, John F. Lyon, J. C. Donnelly and Calvin Philips.

The club decided to take the initiative in some important movements. One is the appointing of a committee to raise \$5,000 to be spent in aiding property owners along Center street to improve that thoroughfare. Nearly two miles of this is the connecting link between the city and the American lake district, one of the grandest automobiling grounds in the country. An effort will also be made to secure a rescinding of the order which prevents autos being taken into Rainier National Park, which lies up in Mount Tacoma-Rainier. A committee was appointed to take this matter up with the Tacoma, Seattle and Portland chambers of commerce.

Sixth Annual Banquet of the A. C. of Philadelphia.

PHILADELPHIA, Feb. 18.—Preparations for the sixth annual banquet of the Automobile Club of Philadelphia indicate that that annual symposium will exceed in importance any similar event in the club's history. Added importance is given the affair by the fact that Governor Stuart and the new Mayor of Philadelphia (election Tuesday) will surely be present. They will be reinforced by other speakers equally prominent in local political, business, professional and automobile circles. Competition seems to be the life of clubs as well as of trade, for since the formation of the hustling Quaker City Motor Club its ancient and dignified prototype has begun to sit up and get busy. The 400 mark in membership will be passed at the next meeting, with prospects of still further additions in the very near future.

Rushing Work on the Chicago Automobile Club's House.

CHICAGO, Feb. 18.—In less than a month the new clubhouse of the Chicago Automobile Club, in Plymouth Court, will be under roof. The huge stone coping, with the legend "Chicago Automobile Club," has been put in place and the archways on which the cars will run in entering the garage already are in position. The membership of the club has almost reached the 600 mark.

THE AUTOMOBILE CALENDAR.

AMERICAN.

Shows.

- Feb. 26-Mar. 2.—Portland, Me., Second Annual Automobile and Power Boat Show, The Auditorium.
 March 2-9.....—Chicago, Second Annual Power Boat Show, Seventh Regiment Armory. W. C. Andrews, manager, 19 E. Huron St.
 March 2-9.....—Minneapolis, Automobile Show, First Regiment Armory, Minneapolis Automobile Dealers' Ass'n.
 March 4-10.....—Kansas City, Mo., First Annual Automobile Show, Convention Hall. Frank L. Woodward, manager, Willis Wood Theater Building.
 March 9-16.....—Boston Automobile and Power Boat Show, Mechanics' Hall and Horticultural Hall, Boston Automobile Dealers' Association. C. I. Campbell, mgr.
 March 13-16....—Omaha, Auditorium, Second Annual Automobile Show, Omaha Dealers' Association. T. Gillian, manager.
 March 18-23....—Providence (R. I.) Automobile and Power Boat Show, Infantry Hall. F. M. Prescott, manager.
 April 1-6.....—St. Louis, Mo., Automobile Show, Jai Alai Building, St. Louis Automobile Dealers' Association.
 April 6-13.....—Montreal, Canada, Second International Automobile and Sportsman's Exhibition. R. M. Jaffray, manager, 309 W. Notre Dame Street.
 April 8-13.....—Pittsburg, Pa., First Annual Show of the Pittsburg Automobile Dealers' Association, Duquesne Garden.

Race Meets, Hill Climbs, etc.

- Feb. 22.....—Los Angeles, Cal., Pasadena-Altadena Hill Climb, Automobile Dealers' Association of Southern Cal.
 Feb. 22.....—Atlanta, Ga., Hill Climb, Atlanta Automobile Association. F. E. Rushlander, secretary.
 Feb. 22.....—Washington, D. C., Aerial Race, Aero Club of America.
 May 30.....—Philadelphia, Hill Climb, Quaker City Motor Club.
 Oct. 19.....—St. Louis, Mo., International Aerial Race for the Gordon Bennett Prize. Aero Club of America.

Motor Boat Races.

- June 8.....—670-Mile Ocean Motor Boat Race, New York to Bermuda. Motor Boat Club of America and Royal Bermuda Yacht Club.
 July 20.....—New York to Marblehead, Mass., 270-mile Motor Boat Race. New Rochelle Yacht Club.
 Sept. 2-6.....—Jamestown (Va.) Exposition, Motor Boat Races.

FOREIGN.

Shows.

- March 7-16....—London, Olympia Commercial Vehicle and Motor Boat Show.
 March 15-23....—Edinburgh, Scottish Cycle and Motor Show.
 April 6-13.....—London, Agricultural Hall Motor Show.
 May 4-15.....—Madrid, Spain, Automobile Exhibition, Palace of Fine Arts, Royal Automobile Club of Madrid.
 May 15-26.....—Zurich, Third Annual Swiss Automobile Show.

Race Meets, Hill Climbs, etc.

- Feb. 23-27.....—Vulturette Contest, Automobile Club of Italy.
 March 20-27....—Nice (France) Automobile Week.
 April 1-16.....—Spring Wheel Competition, A. C. of France.
 April 21.....—Targa Florio Tour (Sicily), Auto Club of Milan.
 April 25-28....—Touring Contest, Automobile Club of Touraine.
 April 28.....—Chateau Thierry Hill Climb.
 May 24-27.....—Vulturette Contest, Automobile Club of Austria.
 May 29-June 1..—Irish Automobile Club Reliability Trials.
 June 3-12.....—Herkomer Cup, Automobile Club of Bavaria.
 June 14.....—German Emperor's Cup, Taunus Circuit, Imperial Automobile Club.
 June 20-22.....—American Gold Cup, Start from New York of European Tour for American Cars. Georges Dupuy, secretary, 1402 Broadway, New York City.
 June 24-29.....—Scottish Reliability Trial, Scottish Automobile Club.
 July 1-July 8...—Grand Prix, Automobile Club of France. (Exact date to be decided upon.)
 July 14, 1908...—Paris to London Aerial Race.
 July 15-18.....—Ostend Week, Record Trials, Automobile Club of Belgium.
 July 21.....—Ardennes Circuit (Belgium).
 July 31.....—Liedekerke Cup for Touring Cars, Ardennes Circuit, Belgium.
 August 1-7.....—Criterium of France, 1,750 Miles Touring Competition and 250-mile Race for the Press Cup. (Exact dates to be fixed.) A. C. of France.

AUTO DOES WORK OF FOUR TEAMS.

SPRINGFIELD, MASS., Feb. 18.—When one Atlas motor truck can deliver 16 tons of crushed stone eight miles in a day, to two, or possibly three tons, for a double team, the term "horseless age" takes on a meaning. The atlas truck made four round trips of 17 miles each between Boston and Roxbury, delivering 16 tons of rock for the Metropolitan Park Commission. The total cost of the day's work, one man only being needed, and

AN ATLAS TRUCK WHICH DID THE WORK OF FOUR TEAMS.

including gasoline and oil, was \$5.44, or 34 cents per ton. A double team making one round trip and carrying two, or at most three tons, would cost \$6.50 per day, or \$2.17 per ton.

In the cut is shown one of the Atlas type B trucks which has been delivered to the park commission, and is especially and finely designed for road work. Both the tank and sides are removable, making it easily convertible into either a merchandise or a sprinkling truck. Four ordinary horse-drawn sprinkling carts could not do the work of this one powerful apparatus. The truck is fitted with the Atlas water-cooled engine of 24-horsepower, and, under load, will travel 10 to 12 miles per hour.

It is interesting to note, especially in Springfield, the home of the Knox Motor Truck Company, that the United States Government recently in advertising for motor trucks, specified the "Atlas Type B" as the trucks desired, and gives the same general specifications as were called for by the Metropolitan Park Commission, of Massachusetts.

DINNER OF THE NEW YORK TRADE.

United action in all matters of interest to the dealer and the garage keeper was the keynote of the speeches at the dinner given by the New York Automobile Trade Association at Healy's, Friday evening, February 15. The work which the association has been doing was clearly shown in brief statements by the officers. In the absence of President Percy Owen, who is in Europe, Carl Page, the vice-president, acted as toastmaster. There was a general discussion of the work which the association has accomplished by having a member on the Municipal Explosive Commission; of its guidance of what has been a new business to everyone, and of its care and development of a line of trade that now runs into millions of dollars in the big city. The speakers included Frank Eveland, C. R. Mabley, Peter Fogarty, C. Andrade, Jr., and Alfred Reeves.

There were numerous suggestions offered for the advancement of the trade as a whole, among them being one by Alfred Reeves, general manager of the American Motor Car Manufacturers' Association, in favor of an "Automobile Sale Week" in New York. The idea is to have a special week in March or April when buyers in the city and the vicinity would know that salesrooms would make special preparations for the showing of new models and special arrangements for demonstrating.

Among those at the dinner and the firms and cars they represented were: H. B. Phenny (C. A. Duerr & Co.), H. H. Cobe (Cobe Auto Co.), V. J. Vashon (Advance Motor Car Co.), H. H. Knepper (Frayer-Miller Co.), F. F. Sampson (N. Y. Transportation Co.), V. A. Viller (Studebaker Automobile Co.), C. B. Warren (Haynes Automobile Co.), W. J. Coghlan (Metropolitan), Frank Eveland (Stevens-Duryea), C. R. Mabley (Smith & Mabley), G. W. Post (Panhard & Levassor), G. A. Knowles, J. F. Plummer (Locomotive), C. Andrade, Jr., Peter Fogarty, Alfred Reeves, Wm. A. Allen, Alfred Semnacher (Russell Co.), W. H. MacIlroy (Delhaye & Palain Agency), W. H. Shutt (H. J. Koehler Co.), C. W. Willis (Hudson Auto Co.), Wm. T. Eames (Harlem Auto Co.), A. G. Fobeken (Mt. Morris Auto Co.), E. S. Partridge (Wyckoff, Church & Partridge), A. H. Chadbourne (Bouton), L. Markle (Corbin), G. M. MacWilliam (Darracq), E. F. H. Cox (De Dietrich), R. H. Fenker (Parkway Garage), C. H. Covell (Parkway Garage), B. Blumenthal, C. E. Domini (West End Garage), R. B. Van Dycke (Berliet), W. Murray (Percy Owen, Inc.), A. J. Robinson (Elmore), Chas. W. Graham (Graham & Goodman), A. M. Thackara, Jr. (Westinghouse), J. J. Evans (Daimler), F. R. Welch (Alborak Garage), C. H. Larson (Oldsmobile), E. Buffum (Empire State Garage), Lee Ephriam (United Auto Co.), P. W. Barton (S. W. Bowman Auto Co.), A. M. Robbins (Aerocar), T. A. Phillips (W. J. Duane & Co.), Jos. Troxell (New Amsterdam Auto Co.), L. F. Albro (Chelsea Auto Co.), M. A. Driscoll, Jr. (Smith Auto Co.), C. S. Silver (Smith Auto Co.), Harry Unwin, J. W. Ball, Carl Page (White Company).

CADILLAC'S NON-STOP THOUSAND.

SEATTLE, WASH., Feb. 6.—While the Middle West was snow bound, the East experiencing gales in zero weather, other sections snow slides or flood troubles, and this section shut off from the rest of the world, excepting by wire communication, a world's automobile record was being established.

At noon, to-day, F. G. Plummer, at the wheel of a one-cylinder Cadillac, completed a 1,000-mile non-stop ride in 71 hours, 32 minutes. This is the best non-stop record for a one or two cylinder car, the best previous distance being 600 miles. The entire distance was covered on the streets of Seattle. The start was made Sunday afternoon, shortly after a fall of several inches of snow. Before the ride was a day old a thaw had set in with occasional showers. But throughout it all the Cadillac kept pounding along, and not for a second did the engine show signs of bucking. The start and finish was made from in front of the *Times* office, and at the back of the seat was a sign which proclaimed: "A-1,000 miles and then some. Still going." The engine was still pumping away when the car

SINGLE CYLINDER CADILLAC WHICH DID A THOUSAND NON-STOP.

was brought to a stop, and the seal broken. The ride was remarkably free from accidents, and the speed limit of the city was exceeded only during the last 50 miles.

During the ride 54.5 gallons of gasoline were used, and this under conditions that demanded an open throttle most of the time. Two gallons and a half of lubricating oil were used. The tires show but little wear.

The Real Nationalization The Hotchkiss administration of the A. A. A. A. A. affairs is quickly making it clear that the new president intends to make the organization of practical worth from a national standpoint. The idea of federal automobile legislation is not new, but previous leaders of the A. A. A. have done nothing but talk and made no concerted effort in a direction which interests the automobilists of the entire country. There is a division of opinion as to the probability of securing a national automobile law, but the measure which Chairman C. T. Terry of the A. A. A. Legislative Board brings forward will call general attention to the subject and ultimately result in securing that which is desired, even though the manner of so doing may be modified to a considerable degree. The subject of inter-State registration is second to no other in point of interest to the touring automobilist.

Though the Brownlow-Lattimer good roads bill has lain dormant for a year or more, Chairman R. P. Hooper of the A. A. A. Good Roads Board believes that national aid in road building is worthy of a revived effort on the part of his board, which upon his early formation will concern itself at once with this ever-pertinent subject. If harbors and rivers can be dredged for water transportation, why, asks the automobilist, cannot general trunk roads be built for inter-State traffic? Certainly it would appear that it should not be unconstitutional for the national government to assist those States which are willing to come forward with a still greater amount of money to be expended in this improvement that is of such vital importance.

Busily engaged in creating State associations wherever possible, the A. A. A. soon will be represented by a flourishing chain of State bodies extending over the entire country, and these working in a national way can bring about untold good to the cause of automobilism.

The Touring Dream of All Automobilists.

No finer touring ground in the world exists for the automobilist than the chateaux country of Touraine. Its accessibility from Paris—though Mr. Miltoun advises and tells how one can arrive in France and reach Touraine by avoiding the gay capital—makes it the most convenient and picturesque territory in the grasp of the stranger whose time is limited and who must needs hurry some in his fleeting glimpse of the Old World. There is romance galore and history in abundance in the valley of the Loire, and the remembrance of it will linger for many a day with those who are fortunate enough to tour through the country which was once the playground of the French monarchs. Mr. Miltoun, knowing his subject thoroughly, has outlined a tour of the chateaux country that economizes in time and gives one an excellent itinerary, comprehensive and gleaned from an extended experience. There will be more American automobiles and automobilists seen in France the coming Spring and Summer than ever before, and to these we recommend the reading of Mr. Miltoun's article, which gives just the sort of information wanted alike by the leisurely inclined as well as by those who are compelled to count the days which they can spare for the most delightful of modern pastimes—automobiling in a good car over the well-built roads of La Belle France. Roads that are as smooth and wide as our boulevards, stretching into the distance as far as eye can reach, replete with signboards and kilometer stones, with sleepy villages and an occasional bustling city in the pathway, what greater delight can one ask for than this healthy open-air travel supplied by the automobile? Some day in our own prosperous land—and we are awakening to the situation with a sudden start—there'll be miles and miles of road that will bring our scenic beauties in the reach of the seeker, driving his automobile, of new sights and a change from his accustomed environment that will amply repay the seeking.

To Prevent Gasoline Reaching Sewers.

Long before New York had any automobiles or garages, corroding and poorly-jointed gas pipes poured their quota into the sewers, and a timely spark from underground electric wires lent variety to urban life by sending iron manhole covers flying into the air with more or less frequent regularity. "Leaky gas pipes" explained to everyone's satisfaction. There are more leaking gas pipes under New York City to-day than ever there were, due to the rapid corrosion of electrolysis set up by underground currents on the wrought and cast iron.

It is conceded that large quantities of gasoline are used daily in city garages for washing purposes, and that more or less of it naturally finds its way into the sewers, but that the proportion is anything like as great as popularly supposed, or that it is responsible for sewer explosions that take place in the financial district or way out in the suburbs, is absurd.

There can be no valid objection to the enforcement of a long-forgotten ordinance, however, compelling the use of a special form of drain trap wherever gasoline is used, but that sewer explosions will be any the less frequent on that account appears doubtful. The strangest thing about this latest attempt to further safeguard the use of an admittedly dangerous fluid is to be found in the fact that householders should smell gasoline vapor from the sewers in their cellars, and nothing else. Queer plumbing, indeed, that will pass one per cent. of gasoline vapor and leave 99 per cent. of sewer gas behind.

MOTOR BOAT SHOW AUSPICIOUSLY OPENED.

Tuesday evening, February 19, witnessed the opening of the National Motor Boat Show in Madison Square Garden, New York. It will continue until February 26. There is every indication that the exhibition will be the most successful one ever conducted under the auspices of the National Association of Engine and Boat Manufacturers, an organization embracing the longest established and leading concerns of the country. Nautical decorations, of course, predominate, yacht club, signal and navy flags covering the balcony fronts. The exhibits typify the latest and best types of motor boat construction, together with a big variety of accessory displays.

Washington's Birthday, February 22, will, as customary, be "Family Day" at the Show, and Saturday, February 23, will be "Children's Day."

Automobilists are numerous in the large crowds which are flocking into the Garden, and even this early sales are reported which bear the earmarks of authenticity. The exhibition surpasses all previous motor boat affairs by a wide margin.

CHICAGO WANTS CONCLUSION A. A. A. TOUR.

CHICAGO, Feb. 18.—Entire satisfaction is felt over the appointment of Ira M. Cobe and S. K. Martin, Jr., to positions on the racing board of the A. A. A. Both men are capable, and the selections will tend to draw the East and West closer together, and will also act as a stimulus upon Western manufacturers who contemplate building cars for the Vanderbilt race.

The Chicago Motor Club has just become a member of the Illinois State Automobile Association, and through this new relation affiliated with the A. A. A. At its meeting Friday the resignation of its first president, William A. Arthur, was accepted, and F. C. Donald elected to succeed him. David Becroft was chosen to fill Mr. Donald's place in the directorate. A committee was appointed with the object of prevailing upon the Glidden Tour Committee of the A. A. A. to change the route of the 1907 tour to the New York-Chicago course, instead of the proposed Chicago-Washington-Jamestown Exposition route.

The Chicago Automobile Trade Association and the Chicago Automobile Club will probably appoint similar committees that the three bodies may work in harmony to secure their desire that Chicago may be the end, instead of the start, of the Glidden Tour. It is argued that should the change be made the entry list would be the largest ever known, as the good hotel accommodations to be secured in the large cities would tend to attract many to the tour who would not make the trip should it go in any other direction.

ANNUAL BANQUET OF THE SYRACUSANS.

SYRACUSE, N. Y., Feb. 18.—The Automobile Club of Syracuse held its annual banquet at the Yates Hotel. Over one hundred members and friends of the club enjoyed the affair. A decided hit was made with an illustration on one side of the menu cards. It represented a polecat awaiting the assault of an approaching automobile. The picture bore the legend: "When Greek meets Greek." Around the banquet room were signs which the club will put in the spring about the county to direct tourists to other cities. President Hurlburt W. Smith called the assemblage to order for the toasts. He referred to the leading part taken by the Syracuse club in the formation of the New York State Automobile Association.

Toastmaster Howard P. Denison read a letter from Frederick H. Elliott, secretary of the Automobile Association of America, formerly secretary of the Syracuse club. Supervisor Robert E. Gilman spoke on the subject of good roads. He said twenty miles of State roads had been completed in this county, and 231 more are to be constructed. He assured the club that the State Highway Commission would not allow any unfair bills to pass the Legislature at Albany. There were other speakers, including Giles H. Stilwell, president of the Chamber of Commerce; William H. Rubin, Police Justice Benjamin J. Shove, and J. William Smith.

WASTE GASOLINE AGAIN A MENACE.

As a result of numerous complaints, said to have been made on the part of New York City householders in what is known as the automobile district, to the effect that the cellars of houses were so filled with gasoline fumes as to make it dangerous to strike a light in them, a hearing was held by Hugh Bonner, chairman of the Municipal Explosives Commission, at Fire Headquarters, in which he discussed the matter with C. R. Mabley, representing the New York Automobile Trade Association; S. M. Butler, secretary of the Automobile Club of America, and Thomas F. Winters, superintendent of the club's new garage. It was decided that all garages should be compelled to install a special form of trap in the drain pipes, so as to catch any gasoline that would otherwise find its way into the sewers. It is customary with chauffeurs to wash the machinery of the cars with gasoline, and also to wash their hands in it to remove oil and grease, the latter practice being the most prolific source of complaint.

Messrs. Mabley and Butler were given the task of settling on some form of trap that would separate the gasoline from other forms of sewage, the device to be officially approved before being finally adopted. This will probably take the form of what is commonly known as a grease trap, or settling trap, except that a cold water jacket will not be necessary. In this form of trap both the inlet and outlet are at the bottom, with a partition or baffle plate between them to facilitate the collection of the grease on the surface. With gasoline no cooling effect will be needed, but some means for drawing off the gasoline which collects on the surface of the trap will have to be provided. In addition, it will be well vented. It seems that there has long been an ordinance calling for the use of such a trap wherever gasoline is used on city premises, but it has never been enforced.

A joint meeting of the committees of the two organizations is to be held during the present week, at which the devices suggested will be passed upon and submitted to the authorities.

BRITAIN'S ENTRY FOR THE VANDERBILT CUP.

PARIS, Feb. 15.—The London correspondent of the Paris *Herald* supplies the following story:

The only British automobile which will compete for the Vanderbilt Cup in America and the Grand Prix in France is of purely British build. It is but a few months since the Weigel workshops were opened in Goswell road, and it only requires a visit there to prove how busy they already are. Though D. M. Weigel is the youngest builder of automobiles in Great Britain, he can fairly lay claim to being the pioneer of automobilism in England, for it was he who in 1893 introduced the first petrol-driven automobile into England. That was three years before the "emancipation act," as it is called, was passed, and a sorry time he had of it with summonses for breaking the law. He has had as many as thirty summonses in his pocket at one time, for which he had to pay, on conviction, the sum of one shilling for each "offense." But he persisted until the police authorities got tired of summoning him, so long as he did not drive to the public danger.

R. Lassen, a member of the Weigel firm, will drive the machine in the Vanderbilt Cup, and he is now in New York.

AMERICAN MERCEDES FACTORY BURNED.

By reason of a disastrous fire of unknown origin which started in the plant of the Daimler Motor Works at Steinway, Long Island, early Thursday morning last, the factory in which the American Mercedes cars were built was totally destroyed, together with a number of machines. Among these were two racing cars, one of which was used at the recent Ormond meet, besides eight completed cars and forty in course of construction. The damage to the plant and contents is estimated at \$500,000, which is said to be fully covered by insurance. The plant was also engaged in the building of Daimler motors and motor boats and employed about 300 men.

CLEVELAND'S SHOW THE BEST OF ITS HISTORY

CLEVELAND, Feb. 18.—The Cleveland Automobile Show, which opened this evening, is by far the most impressive exhibit of automobiles this city has seen. The big Central Armory presents a striking scene. The attendance this evening is the largest that ever turned out for a similar event in Cleveland.

The exhibition of automobiles is very complete. There are 27 exhibitors of automobiles, showing 44 makes of machines, and there are about 150 cars on the floor. The distinguishing feature of the exhibits this year is the great preponderance of the so-called speed car—the runabout. Practically every manufacturer represented shows something on this order, not even excluding the electric vehicle makers. One of the cars shown for the first time is the 35-horsepower Gaeth, built by the Gaeth Automobile Company, of this city. It is a handsome car and sells at \$3,500. A newcomer in the field is the Barnes Manufacturing Company, of Sandusky, O., which shows the Servitor runabout, fitted with a 20-horsepower four-cylinder engine, with friction drive, and selling at \$1,250. The list of exhibitors follows:

Automobiles.

The Auto Shop Company—Thomas and Franklin.
 Barnes Manufacturing Company—Servitor.
 Boulevard Garage Company—Glide, DeLuxe and Queen.
 Chisholm & Phillips Company—Stevens-Duryea.
 Cleveland Motor Car Company—Cleveland.
 Cleveland Oldsmobile Company—Oldsmobile.
 W. B. Davis—Jewell.
 Euclid Garage—Pungs-Finch.
 Ford Motor Company—Ford.
 Gaeth Automobile Works—Gaeth.
 Holmes-Booth Company—Pope-Hartford, Pope-Waverly, Lozier.
 R. H. Magoon Motor Car Company—Pope-Toledo and Locomobile.
 Metropolitan Motor Car Co.—Cadillac, Babcock, Pierce.
 H. S. Moore—Stoddard-Dayton.
 Ohio Motor Car Co.—Buick, Columbia, Haynes, Waltham-Orient.
 George S. Patterson—Reo and Premier.
 Paxon Motor Car Company—Jackson.

Rauch & Lang Carriage Company—R. & L. electric vehicles.
 Reese Motor Car Company—Royal Tourist and Columbus electric.
 Standard Automobile Company—Autocar, Packard and Peerless.
 The F. B. Stearns Company—Stearns.
 Studebaker Automobile Company—Studebaker.
 T. C. Whitcomb Automobile Company—Rambler and National.
 Williams Electric Vehicle Company—Williams electric vehicles.
 White Garage—White steamers.
 Winton Motor Carriage Company—Winton.

Accessories.

American Ball Bearing Company—Ball bearings and axles.
 Auto Equipping Company—Accessories.
 Avery Stampings Company—Steel stampings.
 Bassett-Presley Company—Sheet metals.
 S. F. Bowser & Co.—Pumps and gasoline tanks.
 Coilister & Sayle—Tanks, lamps and sundries.
 Wm. Cramp & Sons—Manganese bronze castings.
 Joseph Dixon Crucible Company—Graphites and lubricants.
 Electric Storage Battery Company—Exide batteries.
 W. C. Farrand—Batteries.
 Ferro Machine and Foundry Company—Gasoline engines.
 Gabriel Horn Manufacturing Company—Horns.
 Gumelastic Tire Company—Tire composition.
 Hartford Suspension Company—Shock absorbers.
 Hoeffcker Speed and Mile Register Company—Speedometers.
 Julius King Optical Company—Goggles, glasses, etc.
 Lorain Machine and Forge Company—Lubricators.
 Charles E. Miller—Sundries.
 L. J. Mueller—Motorcycles.
 National Carbon Company—Batteries.
 Peter Orloff—Furs.
 J. M. & L. A. Osborn Company—Aluminum finish.
 Penn Rubber Company—Tires.
 Perfection Spring Company—Springs.
 Punctureproof Tire Company—Tires.
 Sprague Umbrella Company—Tops and dashes.
 Sherwin-Williams Company—Paints and varnishes.
 Standard Oil Company—Lubricating oils.
 Standard Welding Company—Electrically welded parts.
 United States Graphite Company—Graphite.
 Veeder Mfg. Co.—Tachometers, odometers, counters, etc.
 Warner Instrument Company—Speedometers.

THE CENTRAL ARMORY'S CAPACIOUS INTERIOR SPLENDIDLY ACCOMMODATES THE EXHIBITS AT THE CLEVELAND SHOW.

BUFFALO'S SHOW BRILLIANTLY SUCCESSFUL

BUFFALO, Feb. 20.—Surpassing its predecessors in quality and quantity of exhibits, and, incidentally, in decorative interest, the fifth annual automobile show of the Automobile Club of Buffalo was opened in Convention Hall, Monday night, disclosing to auto enthusiasts of Buffalo and surrounding cities the rapid strides made in the manufacture of automobiles since the last exhibition. Unquestionably it is the greatest exhibition of cars that has been placed before the people of this city in the history of the automobile. It is a revelation in the process of motor car evolution.

Lack of space compelled Secretary D. H. Lewis to deny several applications from well-known manufacturers, and the only regret the management of the show and the people of Buffalo had was that Convention Hall is really too small for a suitable and appropriate exhibition of the American automobile.

Convention Hall is spectacularly decorated for the show. Its bare and forbidding iron girders and cold ceiling are hidden behind a canopy of green and white, and the decorations are artistically and handsomely arranged so as to attract the attention of the people after they have finished their close examination of the many automobiles placed there for their scrutiny. The first thing that catches the eye of the spectator on entering the hall is the decorative work, an ephemeral memory to the credit of the decorator. The entire roof is concealed by a beautiful canopy of white and pea green, which blend admirably. In the center of the hall is a center-piece, like an inverted canopy of green and white, which is studded with nearly 500 16-candlepower electric bulbs, making a brilliant and dazzling spectacle. Reaching from the girders to the rail of the balcony is a huge reproduction of the emblem of the Automobile Club, a painted buffalo head in the center of a tire, on either side of which are spread wings. One thousand incandescent lights make this piece an attractive feature of the show that cannot be overlooked.

Floor space is so divided that the central portion is separated from the side exhibits along the walls by wide aisles, while the central section is divided by a wide aisle running the entire length of the hall. The spaces for exhibits are carpeted with dark green. Over each exhibit is a large sign announcing the name of the automobile, each sign studded with electric bulbs. In this manner nearly 3,000 incandescent lights are placed in the hall, making a scene that for brilliancy has never before been equaled locally.

There are thirty-six exhibitors. Big touring cars, runabouts, trucks, motorcycles, and accessories of every description that are needed in the general construction of an up-to-date automobile are displayed in attractive fashion.

The Pierce "Great Arrow" greets one as he enters the hall. Back of that in the main center space are the Thomas Flyers and the Babcock Electrics, with other types of automobiles of every

description. On a small scale, the automobile show of Buffalo rivals the recent exhibitions at New York and Chicago, and for beauty and fantastic decoration is the best exhibition of its kind ever held in this city. Delegations from Rochester, Toronto, Syracuse, and other cities are announced for later in the week.

The commercial vehicle is also displayed by concerns which devote their plants to the sole construction of this class of horseless conveyance. The opening night brought forth a larger attendance than has ever been seen here.

The following is a list of the exhibitors of the Buffalo Show:

Automobiles.

George N. Pierce Co.—Great Arrow.
E. R. Thomas Motor Co.—Thomas Flyer, Thomas "40."
Babcock Electric Carriage Co.—Babcock electric.
Brunn Carriage Co.—Brunn's electric. Stevens-Duryea.
Auto Car Equipment Co.—Passenger 'buses and trucks.
Centaur Motor Co.—Peerless, Winton, Autocar, Oldsmobile, Cadillac, Pope-Toledo.
J. A. Cramer—Stoddard-Dayton, Mitchell.
Walter Hayes—White steamer, Jewel.
Imperial Motor Car Co.—Packard, Pope-Hartford, Buick.
G. H. Poppenberg—Rambler, Reo, Jackson, Premier.
Maxwell-Briscoe Co.—Maxwell, Mora.
W. C. Jaynes & Co.—Waterless Knox.
A. V. Hart, Rochester—Elmore, Columbus electric.
W. H. Barger—Waltham, Orient buckboard.
Buffalo Automobile Exchange—Franklin.
American Motor Truck Co., Lockport—Truck.
Genesee Motor Vehicle Co., Rochester—Corbin.
Ideal Runabout Mfg. Co.—Ideal.
C. M. Rodgers—Rapid trucks and 'buses.

Accessories.

Charles E. Miller—Automobile accessories.
National Battery Co.—Batteries.
Warner Instrument Co.—Warner auto-meter.
Buffalo Gasoline Motor Co.—Motors.
Acetyvone Co., New York—Gas generators.
James G. Barclay—The Auto-Meter.
Jaynes Auto Supply Co.—Prest-O-Lite tanks, Witherbee batteries, accessories.
Pennsylvania Rubber Co.—Tires.
Ennis-Ruff Tire Co.—Tires.
E. E. Denniston—Tops and bodies.
O. K. Machine Works—Sundries and accessories.
W. F. Polson—Auto accessories.
De Luxe Mfg. & Specialty Co.—Spark plugs.
Townsend Davey—DuBrie motors, Davey tire guard.
Knoll & Turgeon—Automobile insurance.
Travelers Insurance Co.—Insurance.
D. H. Lewis—Automobile route book.

Motorcycles.

Thomas Auto-Bi Co.—Motorcycles.
Neal, Clark & Neal Co.—Indian motorcycles and racycles.

THE "FLAG-TO-FLAG" MOTOR BOAT RACE.

NASSAU, N. P., Feb. 17.—The *Daggett*, owned and steered by John Haggerty of New York, yesterday was the first to arrive of the four official division contestants in the "flag-to-flag" motor boat race from Miami to Nassau. The *Daggett* arrived at 3 P.M.; the *Whiz*, owned by Thomas E. Norton, New Haven, arrived a half hour later, and the *Klondike*, owned by Charles Ball of Miami, arrived at 6 P.M., having lost the lead in a fog bank. The *Lee S.*, owned by A. P. Gerlach, has not yet reported.

The official start was given on Thursday morning, though originally scheduled for Tuesday morning, at which time the *Muriel*, entered in the name of the New York Motor Club, made its start. After a rough voyage, during which its engine went wrong and had to be repaired, the *Muriel* reached Nassau Friday noon, and those aboard it have filed a claim for first prize.

NEW JERSEY'S LAW MAY BE CHANGED.

TRENTON, N. J., Feb. 18.—Several amendments to the present Frelinghuysen automobile law are probable, if an amendatory measure recently introduced with the approval of the Associated Automobile Clubs of New Jersey meets with the favorable consideration which is expected. The amendments include the furnishing of registration tags by the State itself, thus insuring uniformity in size and appearance; the abolishing of the right to arrest without warrant, but increasing to twenty the number of State inspectors, and the recognition of registrations obtained in other States. The automobilists also will urge an amendment to a bill now in progress of passage whereby there would be a white light in front between the wheels and a red light in the rear instead of two side lights. Before action is finally taken it is probable there will be other changes proposed.

WORCESTER'S FIRST SHOW.

WORCESTER, MASS., Feb. 18.—Worcester's first automobile show, in the State Armory, opened this afternoon with all decorations and exhibits except four in place. These were delayed owing to a freight wreck between here and Boston, in which four of the cars figured. A large crowd thronged the drill shed afternoon and evening.

The big hall resembles a palm garden, and to enter the show was like stepping from a New England Winter into a Florida Summer. The ceiling and girders are covered with red, white, and blue streamers and bunting. The walls are covered with crimson burlap, decorated with frieze of white covered with red poinsettias, a crimson California flower. The floor of each exhibit is covered with a green flowered burlap of new design, and each space is marked off with Southern palms, which stand ten feet and more high.

The latest models of automobiles and the other exhibits of accessories are ranged in three lines of booths on each side of the drill shed and down the center, every available inch of space being filled. There are over 100 cars in the exhibition, nearly all of American make, touring cars predominating.

The show is for the benefit of all the militia companies which have quarters in the armory, and each company shares in the

WORCESTER'S SHOW AS SEEN FROM ARMORY GALLERY.

profit. Manager Frederick N. Prescott deserves credit for the manner in which he arranged for the exhibits, many of which came by special train direct from the Chicago show. It is Worcester's first annual and will surely be repeated next year, for every Worcester dealer is represented and each says the show will have to be an annual affair from now out.

The Atlantic Motor Boat Company has a couple of its craft on exhibition, and one of them will be awarded at the end of the show to the militia company receiving the greatest vote.

The exhibitors at the Worcester show are as follows: Norton Emery Company, ground automobile parts and grinders; George W. Knowlton Rubber Co.; Lincoln Holland; Alsten & Goulding; Coes Wrench Co.; Park Square Automobile Station, Boston; C. A. Harrington; George F. Jewett; Apperson Bros., Boston; Brunell Automobile Co.; Boston Motor Co.; Pond Automobile Co.; White garage, Boston store; Iver Johnson Sporting Goods Co.; Birney A. Robinson; Harrington Automobile Station; Page Electric Company; John S. Harrington; George H. Phelps; Pilot Garage; Palace Automobile Station; Norcross Automobile Company; Prentice Motor Car and Supply Co.; and Worcester Pressed Steel Company.

Pittsburg (Pa.) councils have passed an ordinance to buy six automobiles to cost \$30,000, and expend \$21,000 more for the erection of a garage to store them. The purpose is to provide automobiles for service in the parks—especially Schenley Park.

BOSTON'S SHOW IN AN ORCHARD.

BOSTON, Feb. 18.—New York has had its Italian and Swiss gardens and Chicago has seen Manager Miles' automobile art gallery; now comes Boston's turn to show something new in the way of a setting for its annual automobile and power boat show that is to open in Mechanics' Building and Horticultural Hall, March 9, and continue through the following week.

For the fifth annual show of the Boston Automobile Dealers' Association the interior of Mechanics' Building will be transformed into an old-fashioned New England apple orchard and garden. The 1907 product of the automobile factories of America and Europe will be exhibited under the branches of a large number of apple trees in full bloom and under lattices loaded with rambler roses, while all through the great halls pots and baskets of early spring flowers will add to the garden effect of the whole.

Grand Hall, as usual, will be the central feature of the decorative scheme, and to adorn this spacious hall an orchard in Newton has been despoiled of its trees. Some twenty immense trees have been cut down, trunks, branches and all, and upon these the decorators will place leaves and blossoms, and under them the automobiles will be exhibited. The central feature will be the band stand, built of lattice work like a nest in the branches of a huge apple tree, the stand being supported by the branching limbs, and the whole covered by the flower-laden twigs above. This stand will be supported by the trunk of a tree, inside of which a spiral staircase will furnish a means of entrance and exit for the musicians.

Over the stage will be an arch of electric lights, each covered with a cluster of apple blossoms and around the fronts of the first and second balconies pink flowers will be massed, relieved by garlands of greenery. Overhead will be a canopy of the national colors, while thousands of electric lights along the beams will illuminate the entire scene. The exhibition spaces are to be divided by railings of white and mahogany, and all the signs will be of white and gold, with uniform lettering and of uniform size. At the aisle ends of the railings dividing the spaces are to be posts carrying large baskets of artificial flowers. The back walls under the balcony and the posts are to have coverings of green burlap and a green matting will be used to cover the floor of the spaces. To add to the orchard effect, twenty small cherry trees in full bloom are to be placed upon the first balcony railing all around the hall.

In Exhibition Hall, which as well as Grand Hall will be devoted exclusively to the exhibition of automobiles, the decorative effect will be that of an old-fashioned garden adjacent to the orchard. Lattice work is to be used to cover all the beams and posts and to form arches across the main aisle, and through this will twine thousands of yards of rambler rose vine, with countless red blossoms. Intertwined with the rose vine will be something like 4,000 electric lights. The spaces are to be divided as in Grand Hall with white and mahogany railings, and the signs are to be of the same style and character.

The basement, which is devoted almost exclusively to the exhibition of motor boats and their accessories, is to have an entirely different treatment, the intention being to give it as much of a nautical atmosphere as possible.

In the balconies, where the accessories exhibits are to be located, the general decorative scheme is a liberal use of bunting in the National colors with green divisional fences and green matting on the floors.

Horticultural Hall, which is to be used in connection with Mechanics' Building for the show, and in which commercial vehicles and some pleasure cars will be shown, will be treated less elaborately, though in harmony with the other building.

The decorations will not be limited to the interior of the buildings, for on the outside of Mechanics' Building Manager Campbell is planning one of the most extensive electrical displays ever attempted in this city.

NEW TRAFFIC RULES FOR PARIS.

By PHARE.

PARIS, Feb. 11.—Although I am the owner of several large and luxurious automobiles and maintain in my employ an army of chauffeurs, all of whom are saucily uniformed and trained to wear that supercilious, overbearing countenance which harmonizes with their master's rich and princely station, let me for an instant whistle the tune of the proletariat, pipe the plaint of the simple pedestrian, who must needs go afoot.

The "simple piéton," he who walks, has no right on that particular portion of the earth's surface on which Paris is built. Perhaps some mute clause of the Napoleonic code accords him a legal right to cross the street now and then, when his occupation calls for such a move, but in the practical daily routine of existence in the delightful metropolis he finds himself obliged to be on the jump from one sidewalk to the other, with a starting crank or a cab shaft pole always close to his spinal column. The situation of the pedestrian in Paris is quite in keeping with that beneficent designation in French law by which the noble citizen is always guilty until he proves himself innocent, and thus, in case of danger, "it's up to him" all the time.

Vehicles have all the rights in Paris. Policemen occasionally wave white enameled cotillon favors at the drivers, in an almost rude or menacing manner, as if to warn them against doing it again, but up to the present no naked eye has been able to detect anything but much comic opera costuming in the play for the public's protection. Five or six years ago the police department evolved the wonderful scheme of installing crossing "cops" at a few of the busy intersections. This system was inaugurated in Webster, So. Dak., just before the County Fair of 1860. It was soon found to be a good thing in Paris. It is in general operation at about a dozen of the congested street intersections, where the traffic is so dense that no vehicle can go faster than an A. D. T. walk anyhow. Therefore, you see, it is a great success, and citizens point with pride at those stalwart, four-foot policemen who, by raising pretty little white candy sticks, arrest the mad rush of the city's surging throng. Touching is the scene of a frail woman threading her way across these dangerous sections of the boulevard while Monsieur Officer Murphy benignly watches her movements to see that her dress does not trail in the mud.

In the wide avenues, where all kinds of machines on wheels can run as fast as their drivers care to let them run, there are policemen who, about once a month, glance at the rear numbers of flying autos, jot memoranda in notebooks, make mistakes as to the numbers, of course, and summon somebody to the police station two months later.

The avenue des Champs-Élysées, in accordance with the original Gallic plan of subdivision, is in three parts—two sides and a middle. Vehicles may take to the sides or the middle, as they choose. In the middle, theoretically for the use of the public, are "refuges." No pedestrian ever reached any of these havens, but hope springs eternal and comes up smiling like a Truffault suspension, and the "refuges" are there anyway.

But, ho! New regulations are proposed. Something is to be done by the police in the Champs-Élysées. Automobiles must be driven down the middle of the avenue, while cabs, bicycles, coaches and other donkey carts are to have the right of way on the two sides. This will work a change—for the vehicles. How much of an amelioration will accrue to the simple pedestrian does not remain to be seen, as it is already plain. The simple pedestrian, instead of being able, now and then, to get part of the way across the avenue, will not be able to even leave the sidewalk. This will constitute an improvement after all, as the simple pedestrian will incur less danger.

The famed and boasted beautiful avenue des Champs-Élysées remains, however, the grandest public thoroughfare in the world, and of which Paris is justly proud. Incidentally it may be remarked that 200 persons are run down by vehicles, and either killed or badly injured, in the avenue des Champs-Élysées every year, sometimes more but never less.

THE NEWS FROM TIRETOWN.

AKRON, O., Feb. 18.—The Firestone Tire and Rubber Company may go into the United States Supreme Court to secure a final review on the decision of the New York Court of Appeals, which was adverse to the company on manufacturing tires under the Grant patent. The Diamond Rubber Company and the B. F. Goodrich Company are vitally interested in the decision also, as they make the same kind of internal wire tires, and if the suit against the Firestone Company can stand, one can also stand against the other two companies. The Goodyear Tire and Rubber company claims to be protected, however, under a decision in a similar case brought against it by the Consolidated company, and which the Goodyear Company won. The decision, however, will have no serious effect on the tire business in this city, as the companies mentioned make other tires, including cross wire tire, that will not be barred.

The Firestone company has completed preparations for entering what is expected to be the biggest year in its history. The office room of the company has been enlarged and the factory's facilities increased. The greatest enlargements, however, are being made and planned by the Diamond and Goodrich companies, which are erecting new buildings to care for the increased business.

The total actual capital engaged in the rubber manufacturing business in this city, much of which consists of the tire trade, is estimated conservatively at \$17,796,000, with the Goodrich company leading with \$9,000,000, and the Diamond following with \$5,000,000. The Diamond company has just authorized an increase in capitalization from \$3,500,000 to \$4,000,000, and taken steps to further increase the capital stock to \$5,000,000 to care for the increased demands for money in the business.

Fred W. Work and B. J. Maxson, of the Goodrich company, will leave, May 1, for a trans-continental trip in a 40-horsepower Oldsmobile. They will start from New York city, and, after spending a short time in California touring, will come back as they went. This will be the longest trip ever attempted by Akron men. The trip will be solely for pleasure, and no attempt to go against time will be made.

CRATING MUST BE CONTINUED.

For the present, automobilists crossing the Atlantic must crate their machines. The Automobile Club of America, the American Automobile Association and other representative bodies have met a committee of the Transatlantic Associated Trade Conferences, without being able to convert that body to their views. The argument of the shipping people was that steamers are at present so constructed that it would be impossible to accede to the demand. They contend that to protect a car it would be necessary to build a bulkhead right across the vessel, since no ordinary partition could hold the cargo from sliding down on the cars in heavy seas. Such a bulkhead would need to be removed on western trips to make room for immigrants. It was shown that a single car would occupy the space of eight immigrants paying \$30 each for passage. The steamship companies could not see their way clear to sacrifice \$240 in passage money for the sake of carrying an automobile uncrated at the rate of about \$80. It was admitted that on some of the larger boats with high decks it might be possible to make provision for uncrated machines, but the fact that the number of cars carried eastward on a single trip never averaged more than five, was put forth as a reason for not setting apart a portion of the deck between two bulkheads for this purpose. If a regular traffic of twenty or thirty machines were assured, something might be done.

Automobilists present at the conference were: Albert R. Shattuck, chairman of the runs and tours committee; Waldron Williams and A. L. Westgard, for the Automobile Club of America; F. H. Elliott, secretary of the A. A. A.; Alfred Reeves, general manager of the A. M. C. M. A.; and J. S. Marvin, traffic manager of the A. L. A. M.

THE ROE NOVEL MOTOR SCOOTER VIEWED AT CLOSE RANGE.

MOTOR SCOOTING ON THE ICE.

For exciting, blood-warming, nerve-testing sport, automobile road racing must take second place to the new game of motor scooting. It was a thrilling sensation, stretched on the deck of a swift ice yacht, to glide over the frozen surface at the speed of a bird and with the same ease of motion. But with the motor scooter you can give the sailing craft a good start, catch up the rear one, talk to her skipper, rush ahead, pick up the faster boats, and, with a final burst of speed, run right down the line of the fleet and finish before any of them. It is to Nathaniel Roe, of Patchogue, L. I., that sportsmen owe the new sport. Roe took an ordinary 14-foot scooter, with sharp prow and half rounded stern, fitted it with a light gasoline motor and special drive of his own designing, and surprised the Great South Bay men by leaving their sail-driven craft as if standing still. The hull has no distinctive features, being one of the typical scooters seen daily on the Great South Bay. In the forward end of the cockpit is fitted a very light four-cylinder air-cooled gasoline motor developing about 20 horsepower. The engine is of French origin, originally served on a French airship, was exhibited in the States, and sold when its owner found himself in financial difficulties. The motor is mounted on heavy rubber cushions to reduce jar to the mechanism, and is attached only at its forward end. A propeller shaft, without a cardan joint, drives through a bevel gear an ordinary bicycle wheel with reinforced steel rim in which has been riveted a number of case-hardened steel studs about half an inch long. This driving wheel runs within a center board case. By means of a lever at the rear of the case the engine, driving shaft and wheel can be tilted slightly, thus causing the studs of the driving wheel to bite firmly in the ice, touched slightly, or revolve freely. The gasoline tank being right astern, a flexible joint has to be provided to the carbureter; all other parts are contained on the engine frame, and in no way suffer from the tilting of the engine. Immediately behind the driving wheel is the steering apparatus in the form of an automobile steering wheel. It operates by means of wire cables passing over the gunwale to port and starboard to a long, fin-shaped rudder of steel under the boat. When running free the rudder is not on the ice, but a touch of the helm will, by means of its pivoted arrangement, bring the rudder into contact either to port or starboard.

No danger is incurred by the boat running into water, for the wheel casing is the same as that of a centerboard, and does not allow water to enter the craft. When it is desired to run across country a light frame with a pair of bicycle wheels is slipped under the motor end of the boat. The stern is then hitched on to the rear of an automobile and the boat is towed.

Not only is the boat fast on ice, but she does equally well on hard-frozen snow. On the Great South Bay a speed of 60 miles an hour has been attained; with higher gearing it is believed that the boat could travel at the rate of 100 miles an hour. In-

dications point to motor scooting becoming an important sport, and a very keen rival of sail-driven ice boats. A gasoline scooter club is about to be formed, and orders have been given for the building of five of these craft. Nathaniel Roe can already count as converts to this interesting sport such well known automobile figures as Jefferson de Mont Thompson, Harry Payne Whitney, and A. R. Pardington, all of whom intend to own motor scooters in the near future.

POPE CO. ENTERTAIN LEADING TOLEDOANS.

TOLEDO, O., Feb. 16.—The Pope Motor Car Company has as its guests this week about a hundred members of the Toledo Chamber of Commerce. The monster works of the automobile company was visited, each department being thrown open to the visitors for their pleasure and edification. Competent guides were furnished and every detail about the manufacture of an automobile was explained. The visit was one of a number the Chamber of Commerce is taking to the leading industries of the city for the purpose of imbuing the members with a sense of Toledo's importance from a manufacturing point of view.

AN INDIANA MOTORING PROPOSITION.

INDIANAPOLIS, IND., February 18.—On the fate of a bill now pending before the Indiana Legislature depends the success of a huge automobile venture that is, incidentally, a novelty in the automobile world. It is nothing less than an automobile railway, and if the bill becomes a law this new industry will rival the interurban railroads that are now so prominent in Indiana.

Z. T. Sweeney, State Fish and Game Commissioner, together with a number of Southern Indiana capitalists, are back of the scheme. They propose, as a test, to build an automobile railway for a distance of ten miles between Seymour and Brownstown. The rails will be of concrete, but aside from this little information has been given out, as patents have not yet been obtained.

A COMMODIOUS NEW YORK SALESROOM.

A valuable addition has been made to New York's Automobile Row by the opening of the American Mors premises at Broadway and 54th street. It is only fitting that an industry which is rapidly becoming one of the most important in the country should be housed in the best quarter of the city and have a home in keeping with its magnitude. The St. Louis Car Company's new premises in New York comprise offices, salesrooms and garage, all very commodious, luxuriously appointed, and artistically decorated. There is ample space for the display of all the 1907 models of the American Mors, and a complete exhibit is always on hand. Although the season can hardly be said to have begun, L. A. Hopkins, manager of the branch, reports a gratifying number of sales and is looking forward to a record year for the American Mors.

NEW YORK SALESROOM OF THE AMERICAN MORS.

NEWS AND TRADE MISCELLANY.

The Electric Automobile Company, of Savannah, Ga., has elected officers for the ensuing year as follows: President, Joseph S. Walker; vice-president, R. M. Hull; secretary and manager, George A. Mell.

The Orlando E. Weber Company, Chicago, representatives for the Pope lines, has leased the premises at 1322 to 1326 Michigan boulevard for fifteen years. The store has a frontage of 60 feet and is 171 feet deep.

The price of the Berliet 40-horsepower touring car is \$7,500 and the 40-horsepower limousine or landaulet \$8,500. In a recent number of *THE AUTOMOBILE* the price was stated at \$8,500, but the type of body was not clearly indicated.

In a broad challenge issued several days ago, E. P. Brinegar, the San Francisco agent for the Oldsmobile, offered to match one of the 1907 Oldsmobile touring cars against any car of its class in an endurance run from Los Angeles to San Francisco.

Henry Nyberg, manufacturer and dealer in automobiles, will have new building at 2437 and 2439 Michigan boulevard, Chicago. A six years' lease has been entered into by which the owners will erect a two-story building, 50 by 165, to be ready for occupancy May 1.

An extensive top-making department is now being carried on by the Capital Auto Company, of Indianapolis. A specialty is also being made of folding wind shields and Reliable jacks. Originally capitalized with \$25,000, the company has recently increased its capital stock to \$50,000.

Columbia cars have their motors tested not only on the block and in the finished car, but after assembling they are connected to the main shafting and limbered up. In this manner the various parts are run in so that when a purchaser receives his car he has the assurance that his engine will run smoothly.

Having received numerous demands for catalogues from all over the country addressed to the Huntington Auto Company, Bartlett & Frazier, of Huntington, Ind., are obliged to make a public announcement that these must be intended for some other car manufacturer in another State, doing business under this name.

The Pontiac Iron Works Company is a co-partnership which will equip a new factory and machine shop in Pontiac, Mich., for the manufacture of a gasoline engine shortly to be put on the market by a Detroit firm. A. M. Skinner and E. G. Meyer, of Grand Rapids; W. H. Higgin, of Saginaw, and E. F. Skinner, of Detroit, will constitute the firm.

There are advantages in an automobile factory being located in a small place where the authorities do not have as much organization and discipline as in a big city. At Ardmore, Pa., the authorities and the road testers of Autocars get along like cronies. They are both reasonable and it is said that never has a road tester from the factory been arrested.

Thanks to the ingenuity of a Menominee, Mich., blacksmith, a couple of Escanaba autoists were able to proceed on their way a short time ago after having been held up by snow. The party had

passed Menominee on the way to Wallace, but had to return on account of deep snow. Then Joseph Beyer, a blacksmith, improvised a pair of runners for the front wheels and the auto was able to proceed.

To say that Michigan is full of automobiles which are worn out and ready for the junk heap would be putting it mildly. The fact, however, has been discovered since the auditor general has been sending out blanks for the description of personal property for the purpose of taxation. According to the value placed upon some of the machines by the owners even a Digger Indian could afford a whole trainload.

Lethbridge, Alberta, Canada, is to have the first automobile manufactory in Western Canada. The following have incorporated the company, which expects to turn out the first machine in a couple of months: President, M. Freeman; secretary, C. B. Bowman; mechanical superintendent, Howard Case; directors: Dr. Mewburn, L. M. Johnstone, T. M. Evans, L. Pabst, W. Henderson, Howard Case.

Joseph J. Mandery, the pioneer automobile dealer of Rochester, N. Y., seven years ago drove the first steam automobile through the streets of that city. Like other cities Rochester claims more automobiles in proportion to its population than any other city in the country. Mr. Mandery asserts, as a result of his experience, that it was more difficult in the pioneer days to sell a \$750 steamer than it is to dispose of a \$5,000 automobile to-day.

A splendid example of the utility of the automobile on country roads in the worst weather is shown by the thirty-miles trip from Aguilar to Trinidad, Col., performed by a Model D rapid twelve-passenger automobile. A blizzard was blowing all the time, street cars, trains and all other vehicles were severely handicapped, but the auto successfully came through its test. No other conveyance was able to make the journey.

A. M. Andrews, who conducted in the First Regiment Armory, Chicago, last fall what was announced as an "automobile parts show," gives out information that he has leased the same armory for September 21-23 and intends to hold another show for the "National Association of Automobile Parts Manufacturers," of which he appears to be the general manager, stating that he was named to take charge of the show at a meeting held some time ago.

When the Chicago branch of the Ford Motor Company was burned out offers were received from nearly every member on the row. Temporary quarters were taken in the new Furniture Exchange Building and in a very short time business was going on as usual. The loss on the building and stock destroyed by fire is estimated at \$100,000. C. A. Eckstrom will be the architect for the construction of the new store, which will probably be a three-story building, at the old location, 1442-1446 Michigan avenue.

The first automobile show in America was held September, 1900, at the Washington Park Track, Chicago. Practically all of the makers then doing business exhibited, and it is a curious fact that, of all the exhibitors, the Winton Motor

Carriage Company is the only one now doing business in the same product, in the same name, in the same city, and under the same owners as then. Another interesting fact is that Winton cars won every race in which they started at the show and established a long string of records that stood for several years.

A new use for the automobile engine was recently found by the Buick Company, of Flint, Mich., when the pattern room of the experimental department of the factory was obliged to shut down owing to a break in machinery at the power house. Then the novel plan of employing an auto taken from the stock to do the work was employed. A 22-horsepower stripped car was used. A belt ran from the transmission wheel of the machine to the line shafting on the ceiling, supplying power enough to operate a score of bench machines.

A side light on the value of the automobile for difficult service is shown by the letter received by the Rapid Motor Car Company from the Trinidad Transportation Company. The letter states that the Rapid twelve-passenger car, after running on the streets and many outing trips into the mountains, was, on December 23, 1906, put on a regular run connecting the towns of Aguilar, Hastings, Tabasco, Suffield, Bowen, etc., giving a regular daily service of seventy miles, seven days in the week, carrying full load, fifteen passengers in and sixteen out, over natural mountain roads at an average speed of ten miles an hour. During all the time not a single replacement was made on the machine.

A receiver has been asked for by Paul Picard for the Tileston-Picard Company, formerly Chicago agents for the Renault. According to the claims of Picard he entered into an agreement with C. A. Tileston, March 8, 1906, to take charge of the Chicago agency and for his services he was to be paid a salary of \$250 per month and a share of the profits. In September, he states, the company was unable to continue its agreement with the manufacturers of the Renault and the agency was closed. Picard further asserts that Tileston, who was the president of the agency, and Charles F. Terhune, secretary, are withholding his share of profits made by sales of automobiles, and he asks that an injunction be issued restraining them from using any of the agency's books or papers.

Elaborate and effective measures are taken by the George N. Pierce Company, at Buffalo, for testing every part used in the construction of the machines. There the plant is divided into many departments, with a foreman-inspector in charge of each. These foremen have nothing to do except see that every single article turned out from their department is perfect; and they are held responsible. Thus there is practically an inspector for each group of parts in the machine. When a Great Arrow is completed it is passed over for road testing before being shipped. If, in the strenuous testing on the road, any little thing is found at fault, it is possible to lay the hand on just which man in all that great factory is responsible. The result is that when a car is given to the road testers it is really ready for use.

The regulation method of testing newly constructed gasoline motors is to belt them up to a shaft or run them independently on gasoline. In both cases

there is a certain amount of expense, for the engines have to be watched and their fuel consumption is not negligible. At the Elmore Manufacturing Company's factory, at Clyde, Ohio, the well-known Elmore two-cycle motors are made to test themselves and at the same time furnish the power to run the factory. They are fed with coal gas, and their running is so steady that the incandescent lights show as little variation as with a dynamo run with steam power. Experiments have shown that the Elmore motor can be run satisfactorily with almost any kind of fuel. Some time ago at the Detroit Y. M. C. A. motor class an Elmore was run on gasoline, kerosene, alcohol, brandy, and finally a mixture of all four liquids, without any alterations or adjustments. Alcohol can be used with very good results, its price being the only drawback to its general adoption.

NEW AGENCIES ESTABLISHED.

Knox cars are now handled in Newark, N. J., by the Ellis Motor Car Company of that City.

Dragon cars will be handled in Cleveland, O., by the United Motor Car Company, with headquarters at 6112 Euclid avenue.

Bartlett & Frazier, of Huntingdon, Ind., have been appointed agents for the Buick line of automobiles in the central eastern counties of Indiana.

The Standard Lamp Manufacturing Company, 43 South Canal street, Chicago, and Charlotte, Mich., has opened a branch store at 1670 Michigan avenue, Chicago.

The Union Automobile Company, of Bellingham, Wash., has been organized with a capital stock of \$10,000 by H. J. and G. E. Crockett. The company will handle the Cadillac.

Premises at 248-252 Jefferson avenue, Detroit, will be occupied by the Winton branch house pending the erection of a modern garage. Thos. Winton Hender-son, formerly of Paris, Philadelphia and New York, is in charge.

The Elmore Manufacturing Company, of Clyde, Ohio, makers of the well-known two-cycle Elmore line, has placed the Chicago agency for the Elmore with Owen H. Fay, 245 Michigan avenue. Mr. Fay's establishment, which is one of the best known auto livery establishments in Chicago, occupies the quarters formerly the home of the Chicago Automobile Club.

During the Chicago show the Bartholomew Company made arrangements for the following new agencies: W. B. Vandecar, Grand Rapids, Mich.; O. G. Roberts & Co., Columbus, Ohio; Allegheny Automobile Co., Allegheny, Pa.; Guy J. Hartwell, Mobile, Ala.; Migliavacca Company, Seattle, Wash. All of the above parties will handle a full line of Glide four and six-cylinder cars during 1907.

Branches have recently been opened by the H. W. Johns-Manville Co., of New York City, manufacturers of asbestos, magnesia and electrical products, at New Orleans, Dallas and Baltimore, so that there are now sixteen branches throughout the United States. A new branch has just been opened at 214 Main street, Buffalo, consisting of large retail shops, offices and warerooms, to be under the management of Geo. A. Schmidt.

PERSONAL TRADE MENTION.

On February 4 H. L. Warner ceased all connection with the Muncie Auto Parts Company, of Muncie, Ind.

Roger B. McMullen has been appointed general sales agent of the Hydrant Pressed Steel Company, of Cleveland, Ohio.

Bartlett J. Smith, who has been devoting considerable time to the study of the mechanical side of S. & M. Simplex cars, has joined the Smith & Mabley sales forces.

Andre Massenat, general manager of the American branch of the Panhard Company, has returned to New York from France, where he has been spending a few weeks at the Panhard works.

Webb Jay, who recently resigned the managership of the Chicago branch of the White Company, it is stated, will affiliate himself with a manufacturing house in New York State, which will enter the automobile trade, building a steam car. The management of the automobile department has been tendered to Mr. Jay.

A. B. Barkman has succeeded C. W. Kelsey, resigned, as Eastern sales manager of the Maxwell-Briscoe Motor Company, Tarrytown, N. Y. Mr. Barkman has been connected with Maxwell interests for some time past, and is well remembered as a prominent figure in the cycle trade. He was in charge of the bicycle interests of A. G. Spaulding & Brothers for many years.

A recent addition has been made to the selling force of the American Mors branch of the St. Louis Car Company in New York in the person of A. L. Bennett, formerly sales manager of Cryder & Company, the United States representative of the French Mors car. Mr. Bennett was formerly with the Dietrich Company, and later was assistant manager with the Société Mors, American branch.

C. W. Kelsey, who has been actively identified with the Maxwell-Briscoe Motor Company's interests as sales manager for several years, feels that an undesirable impression may have been created on account of an announcement made last week regarding his resignation from the Maxwell-Briscoe Company. Mr. Kelsey states that the most pleasant relations exist between the Maxwell-Briscoe Company and himself; that his resignation is not due to any friction between the two, and he has had the step in contemplation for some time, his recent trip abroad having been with a view to gather any information regarding the new projects which are now forming and in which he has important interests. Officers of the company confirm this statement. It is known that Mr. Kelsey has in view embarking in the commercial vehicle business. Plans which have practically been completed insure the announcement, at a very early date, of a large company which will devote itself (in the more important cities of the United States, beginning with New York, Philadelphia and Boston) to a development of municipal delivery systems. This company has large capital behind it, and has already practically secured control of a large and well-equipped manufacturing plant. The new company, of which Mr. Kelsey will be the executive head, will not place any cars on the market, but will confine itself to manufacture and operation.

PRICE OF COLUMBIA MARK XLIX.

Through an error the price of Columbia Mark XLIX, 40-45-horsepower touring car was given in a recent advertisement as \$4,200 instead of \$4,500, the correct figure. That current automobile advertising is extensively read was well shown by the numerous inquiries received by the Electric Vehicle Company asking whether the price of Mark XLIX had been changed.

WAYNE AND DRAGON AGENCIES CONSOLIDATED.

One of the largest recent automobile deals in the metropolitan district was put through, February 14, when the Wayne and Dragon New York agencies were consolidated. Messrs. Bishop, McCormick & Bishop turned over their New York City interests to the Kull Automobile Company, of New York, with A. L. Kull as general manager. The Kull company will move from its present address to the present Dragon salesroom, No. 1677 Broadway, before March 1. The details of the deal were arranged by President John Kane Mills, of the Dragon Automobile Company, and A. L. Kull, who has been handling the Wayne car in the East. The transaction was more or less complex owing to the several firms and large financial interests involved. The Brooklyn and Long Island City agencies of the Dragon will remain with Bishop, McCormick & Bishop, and that firm will also handle the Wayne car in that territory in the future.

DOINGS OF THE PENNSYLVANIA RUBBER COMPANY.

The demand for the products of the Pennsylvania Rubber Company, of Jeanette, Pa., has led to the appointment of a general sales agent and the opening of two additional branch houses, one in Cleveland and the other in Detroit. Roger B. McMullen, one of the best-known men in the trade, has been made general sales agent for the Pennsylvania tire. He was formerly manager for the American Motor Car Manufacturers' Association, general sales agent for A. O. Smith & Co., of Milwaukee, and for five years prior to 1898 was a jobber of bicycle parts. Mr. McMullen is located at 1241 Michigan avenue, Chicago.

The new Cleveland branch occupies an entire building, and is in charge of C. W. Moody and W. T. Walker, as associate managers. Mr. Moody has been closely identified with the rubber trade for upward of a dozen years, and is widely known. Mr. Walker, for the past two years, has been connected with the Pennsylvania Rubber Company's New York house, and prior to that was in the automobile business in Indianapolis.

The Detroit branch is well equipped. O. H. Joy had 18 years' service with the Wolverine and Diamond Rubber companies, having been secretary and treasurer of the former, and in the manufacturing and sales departments of the latter. Associated with him is George O. Goble, a mechanical expert and a specialist in the manufacture of jarrings.

The American branches are located in New York, Chicago, Philadelphia, Boston, Buffalo, Atlanta, Cleveland and Detroit. The large English and continental trade is handled from the London branch, located at 26 City Road, this end of the business having assumed unusual proportions during the past year or so.

THE AUTOMOBILE

VOL. XVI.

NEW YORK—THURSDAY, FEBRUARY 28, 1907—CHICAGO

No. 9

THE MOTOR BOAT HAS ITS OWN GARDEN SHOW

By R. F. KELSEY.

DEVELOPMENT of the explosive type of motor for marine purposes has been coincident with its development for automobile, but in somewhat different lines and in keeping with the conditions governing the uses to which it is put. Scarcely ten years have passed since the crude productions of the pioneers in the industry were fitted to a few hulls and launched with some trepidation upon the sea of experiment, and it is only within the past five years—or to be more exact, the past three years—that the marine motor has reached the advanced state of development commensurate with the requirements of present day conditions.

Of necessity a radical change has been necessary in the design and construction of hulls. Power above decks, as represented by sails, and power below decks, as represented by motors, called for hulls different in character, and the working out of problems by a slow and costly process of elimination.

How well this has been accomplished has been exemplified to a nicety at the Motor Boat Show which closed this week in Madison Square Garden, New York City, after a week of splendid success, both from the standpoint of business transacted and patronage by the public.

The exhibition was the first distinctive motor boat show held in the metropolis, the sportsmen's exhibit, which has heretofore been held in conjunction with it, having been discarded as a feature. The National Association of Engine and Boat Manufacturers had full control of the show, and as the organization is comprised of the oldest and most firmly established houses in the country, the exhibits were thoroughly representative and varied.

Pleasure craft, of course, predominated; in fact, practically comprised all that was shown, and the infinitely wide range of design attainable in this category presented a fine field for

study for those nautically inclined. The absence of purely racing freaks was noticeable, the trend of design seeming to lie in the direction of trim, substantial-looking hulls, so built as to admit of high speed if suitably horsepowered.

Increasing Popularity of Trunk Cabin Cruisers.

In contrast with this type, the cabin cruisers, with sea-going properties, formed a pleasing relief with their roomy cabins and homelike accommodations, to their slenderer, fleetier sisters. Cabin cruisers are rapidly gaining in popularity, with those who like to venture off shore out of sight of land, and are now built in a distinctive type from 27-foot length upward. Seaworthiness, not speed, is their chief characteristic. They are full-bodied, moderate in beam, of full wide stern, and the most advanced type shows relatively small displacement aft, the deadwood of the keel reaching almost to the waterline, and the line of recession aft on the bottom commencing about amidships.

The installation of a power plant in a craft of the above type has always been more or less of a problem, but it is best exemplified in a location at the rear of the cabin, about two-thirds of the way aft. This allows short reaches for the controlling levers which should be handy to the helmsman, who necessarily should be able to control the engine of a boat of this type at all times and on all occasions. It should be remembered also that the wheel in the type of boat mentioned must necessarily be located at end of cabin above deck, and its immediate proximity to the motor is desirable.

THE ELCO "EXPRESS," AN UP-TO-DATE PLEASURE CRAFT.
Exhibited by the Electric Launch Company, Bayonne, N. J.

Necessarily the larger type of motor boats could only be shown by miniature models, and the exhibit of these showed tour—the *Aida*, 80 feet; *Lydia* and *Cactus II*, 75 feet each, and *Norka*, 67 feet. All of these are full trunk cabin yachts, and range in speed from 20 miles per hour in the *Aida* to 17 miles per hour in the *Cactus II*.

Steel boats, shown in variety at several exhibits, demonstrated a marked improvement in design over last year's models, also superiority in construction. They embody distinct characteristics peculiar to the nature of the body material, but present no difficulty in their ready adaptation to power propulsion; in fact, their increasing numbers prove a widespread popularity.

A newly-named model for the coming season is the high-speed "runabout," a semi-racing type of boat, fitted with lightweight highly-developed motors of well rated power. These boats are made in popular lengths, the 21-footer predominating in the exhibits made. In power-driven yacht tenders a tendency is shown among builders to combine the large carrying capacity of the ordinary tender with the speed and convenience of the runabout type mentioned above. One type shown was equipped with 25-horsepower motor, has a guaranteed speed of fifteen miles per hour, and a total weight of only 1,350 pounds—a remarkable combination for a serviceable craft.

Selling Price of Products Meets All Purposes.

The wide range of prices for fully-equipped motor boat outfits puts them within the reach of everyone's pocketbook. The lowest price quoted was \$94.50. This, of course, was for

DISPLAY OF STEEL MOTOR BOATS IN ALL SIZES AND TYPES.

THE CHARACTERISTIC AND SERVICEABLE POWER DORY.
Exhibited by the Atlantic Company, Amesbury, Mass.

a very small boat, with a motor of minimum horsepower, but it told the possibilities of the industry and its ability to meet the widest range of demand. Moderate powered boats, from 18 to 25 feet, selling all the way from \$250 to \$1,000, according to finish, horsepower and equipment, formed the bulk of the popular-priced models in open boats. Above the range of one thousand dollars in price there are numerous stock models up to \$5,000, and above that price special designs prevail. Half cabin cruisers can be purchased as low as \$1,500, but the popular sea-going type, 31 to 40 feet in length, ranges from \$2,500 to \$3,500. The largest boat shown was a forty-foot full cabin launch, beautifully furnished, and finished in natural polished mahogany, a \$10,000 beauty.

As is the case with the automobile industry, manufacturers of supplies, fittings and equipment are finding a very productive field in the realm of the motor boat. The balconies were devoted to these exhibits and a number of others found space on the main floor to show their wares. The most rapid advance noted among the specialists is in improved methods of ignition and the development of electric lighting plants for power boats. Names familiar in the automobile sundry supply dotted the big Garden, demonstrating the common kindred business interest which dominates all motor-driven conveyances, whether terrestrial or aquatic.

POPULAR TYPE 31-FOOT CABIN CRUISING MOTOR BOAT.

NAVY CONVERTED TO MOTOR BOAT IDEA.

Rear Admiral Coghlan, U.S.N., paid a tribute to the value of the power boat in his remarks at the beefsteak dinner of the Motor Boat Club of America at Reisenweber's last Saturday evening. He said that while the members of the club were interested in the development of the motor boat from a pleasure point of view, he took a broader view of the future of the industry. To have mentioned a gasoline motor and its use by the navy a few years ago to any prominent naval officer would have caused a shock to the officer. Now the motor boat, with its internal combustion engine, is a recognized thing in the navy, the service having realized the advantages of the motor boat as an auxiliary for light and rapid work. The Admiral said that the motor boat show had been a revelation to him and to all the officers of the navy who had visited it, and he felt that its influence would result in advancing the motor boat not only as a pleasure craft but for business use everywhere.

A CEMENT ROAD ACROSS THE COUNTRY.

INDIANAPOLIS, IND., Feb. 25.—Ezra Meeker, who has just completed a trip over the old Oregon Trail in a prairie schooner with oxen, as he did 50 years ago, is advocating a road bed of cement from the Atlantic to the Pacific.

"Those who would say that this is a chimerical scheme should be reminded that 20 years ago the electric car was unknown," says Meeker. "It is less than 60 years ago since the first railroad was built into Indianapolis, and many persons at that time shook their heads at such a 'wild scheme.'"

POWER BOAT ASSOCIATION'S MEETING.

At the annual meeting of the American Power Boat Association, held February 20, at the Hotel Knickerbocker, New York City, officers were elected for the ensuing year and arrangements made for the race for the Gold Challenge Cup in August, the Gravesend Bay to Hampton Roads contest and the two cups given by the Brooklyn Yacht Club. The total membership of the association was brought up to forty-five organizations by the election to membership of the Hampton Roads Yacht Club, Bergen Beach Yacht Club and Maumee River Yacht Club. J. Norris Oliphant of the Thousand Island Yacht Club was re-elected president of the association, Anson B. Cole of the Manhasset Bay Yacht Club secretary, and J. H. McIntosh of the Columbia Yacht Club treasurer.

It has been arranged that the annual cruise shall be to Jamestown, to arrive there during the week of motor boat racing the first week in September. The route and details of the cruise have been left to the committee. For the Brooklyn races competition will be allowed during the entire summer, the boats making the best corrected time between Gravesend Bay and Hampton Roads to receive the cups. It was announced that the Thousand Islands Yacht Club had again challenged the Chippewa Yacht Club for the Gold Challenge Cup.

BOAT AND ENGINE BUILDERS MEET AND DISCUSS PLANS

MONDAY afternoon, February 26, the National Association of Engine and Boat Manufacturers, under whose auspices the show was held, came together for its annual business meeting at the Hotel Breslin, preceded by a luncheon. An address of welcome was made by President Amory of the association, in which he reviewed what has already been accomplished and outlined what he considered good policy for the coming year. The following were elected members of the executive committee for three years: John J. Amory, H. N. Whittlesey, W. J. Reynolds, James Truscott and Walter Ferguson, Jr.

The matter of shows was naturally to the fore, and while it has not been actually so decided, it is definitely understood that

henceforth there will be an annual circuit of independent motor boat shows at New York, Chicago and Boston under the auspices of the National Association, the latter, in all probability, working in conjunction with the Western and New England associations. In connection with the motor boat carnival to be held on the Hudson River next September, it was decided definitely to hold a manufacturers' convention. The association has made arrangements to pay the transportation of out-of-town members to all meetings in order to insure bringing widely scattered interests together. Among other things discussed was that of the formation of a mechanical branch for the investigation of technical matters, also the founding of an experimental station.

DOCK FIVE-CYLINDER SELF-STARTING MOTOR. †

CRAIG MOTOR FOR THE 670-MILE RACE TO BERMUDA.

FEATURES OF MOTOR DESIGN SHOWN AT GARDEN

MOTORS here, there and everywhere appear to briefly express what may really be said to constitute the *pièce de résistance* of the Motor Boat Show. There are other things shown beside motors, to be sure, but for one sharp on lines and hull construction there are twenty on engine details, and, in consequence, the mechanical end of the show has really come in for the greatest share of attention. It has fully deserved it, too, for seldom in past years has there been such an attractive array of novel things to be studied and so much to be learned as has been the case with the show just past. For obvious reasons, the building of marine motors is still far from that settled stage of standardization that has marked the automobile motor as a whole for the past year or two, and, hand in hand with its trend toward that goal, there are being developed a number of systems which promise well for the future.

Primarily, the business of building marine motors meant the two-cycle type, but with the demand for, not alone greater power but also much greater speed, the four-cycle was resorted to with such success that there is now an almost equal division of opinion on the subject, not a few makers building both types. For moderate powers and speeds, the two-cycle still reigns supreme, particularly in the smaller boats, in which class are included all those not equipped with engines of more than 20 horsepower. Over this limit the four-cycle type of engine is practically universal, and as represented at the show there were many novelties of construction to attract attention. In adopting the four-cycle type, it is particularly noticeable that designers have shown a decided leaning toward marine standards as exemplified in the steam engine, though with this exception the four-cycle motor was in the great majority of instances but an adaptation of the automobile motor to a new environment. As a matter of fact, in some instances, the engine could have been lifted out of a launch and placed directly on a car with but few minor changes, necessitated principally by the need for starting it from a distance, as where it was located under the forward deck.

Multi-Cylinder Types a Feature.

Probably the most striking feature of the showing of motors, as a whole, is the extent to which multi-cylindered engines predominate. But a few years ago, a motor having more than two cylinders was quite an exception to the general rule, and even at that it was usually a three-cylinder type, the prevailing designs being single, two and three-cylindered, and the former two far outnumbering all others. Now the four-cylinder motor is well to the fore, as the result of the adoption of the four-cycle type, and six-cylinder motors are also quite common. In fact, it may well be said to be a six-cylinder show, from the number of this type that were to be found at the various stands.

Beginning with the huge 300-horsepower six-cylinder Standard, which gained the world's record for speed in the launch of the same name, it was noticeable that there were six-cylinder engines of varying powers at the majority of the stands. At the exhibit of the Gas Engine and Power Company a six-cylinder 100-horsepower Speedway motor was running under its own power, gas being employed as the fuel. The valves are concentrated on the right hand side, the exhaust being at the lower part of the pocket and the inlet the upper, the latter operating with an overhead rocker and push rod, and the exhaust by direct thrust from the camshaft, as on the automobile type. The inlet manifold is a perfectly straight bronze tube lying parallel with and directly at the inlet valves, the carbureter being placed at the lower end of a right-angled offset at about the level of the base. Ignition is by means of an Apple dynamo and set of accumulators, the generator and water pump both being driven from an independent shaft. Duplicate ignition employing make-and-break ignitors supplied by a Simms-Bosch low-tension magneto, and the usual jump spark with an Apple ignition set, are used on the 200-horsepower six-cylinder engine shown by this firm, which has a double jet, water-jacketed carbureter supplied by a small pump, a constant level being maintained by means of an overflow.

Some Motors That Attracted Attention.

Holding the distinction of being the lightest marine motor of its power ever built, the power plant of the high-speed motor-boat "Den," both the engine and hull of which were designed by Herreshoff, came in for an unusual amount of attention. It is of the four-cylinder, four-cycle type, patterned after auto practice, and complete with its reverse gear and all controlling mechanism only tips the scales at 1,200 pounds. Its dimensions are 7-inch bore and 7-inch stroke, and it is rated at 120 horsepower. These engines are built from Herreshoff designs by the American and British Manufacturing Company, Bridgeport, Conn. A six-cylinder four-cycle motor, rated at 50 horsepower and known as the H & H, combined quite a number of unusual features of design and construction that served to distinguish it. The valve mechanism was of the overhead type run from a single camshaft supported on bearings on the cylinder heads, and every part was designed to be readily dismantled. But its most interesting feature lay in the method of ignition, which was by means of a small high-frequency inductor alternator mounted directly on the timer shaft. This generated an alternating current at 122 volts, which was sent through a step-up transformer and raised to a potential of 32,000 volts, thus dispensing entirely with brushes, coils and tremblers. The Truscott motors, which were shown in a large variety of sizes and powers, also came in for favorable attention by reason of their simplicity and compactness,

HERRESHOFF 120-H.P. MOTOR FROM THE "DEN."

as well as their apt name of "Heavy Duty." An exhibit that was a constant center of interest throughout the show was that of the Lackawanna motors, one of which was shown running a propeller in a small inclosed tank of water. The ease with which it could be reversed, whether running on the battery or a magneto, proved a surprise to the majority of spectators. This firm showed a most complete range of motors, including a very compact six-cylinder type, composed of three of their well-known units, beside which there was also on view a 12-horsepower set for stationary duty.

Compressed Air Self-Starting Device.

The self-starting Dock engine, built by the New York Safety Steam Power Company, proved to be a surprise in the shape of a five-cylinder motor of the open base marine type that combined an unusual number of meritorious features. With this number of cylinders, the cranks being at 72 degrees, the engine is never on a dead center. Starting is accomplished by means of a supply of compressed air maintained by a small air-compressor. Opening a small cock for a moment sends a stream of compressed air through the carbureter and supplies the cylinder that is in the firing position with a charge of explosive mixture under compression. Starting is facilitated by the system of ignition employed, which may aptly be termed a "constant primary circuit" type. That is, the accumulators are switched onto the single coil and left on closed circuit as long as the motor runs, the secondary current being sent to the various plugs by a special form of distributor, using no actual contacts, the current leaping to the revolving arm as it passes over the terminals. This secondary timer is constructed of hard rubber and brass and covered with a glass plate, so that its operation may be inspected at any time.

Though James Craig is a well-known builder of both six and

SUBMARINE EXHIBIT OF WITHERBEE ACCUMULATORS.

eight-cylinder types, his exhibit only included engines of three and four cylinders, these being of the open base marine type with the superimposed valve gear that has always distinguished the products of this maker. The Holmes long-stroke "get-at-able" motor is another of the open-base type with typical marine connecting rods and method of lubrication, but is closed when running by easily removable side plates. Its fine finish and mechanical excellence attracted no end of favorable comment. The Brownell-Trebert Company, Rochester, N. Y., are also very strong advocates of the six-cylinder type, and showed both fours and sixes in their exhibit. They make both the superimposed valve type and the plain. The Buffalo Gasoline Motor Company, Buffalo, New York, showed a complete line of its models in various sizes. A novelty was the Ramsey marine engine, in which the cylinder is offset on the crankshaft the length of the crank throw.

Kerosene Burning Engines in Evidence.

That considerable study is being devoted to the question of running marine engines on fuels other than gasoline was evident from the number of engines designed to run on kerosene. Chief among these was the Monarch line of engines, of which a six-cylinder type was shown. The regulation Schebler carbureter is used, the heater for vaporizing the kerosene being maintained at

"SIMPLEX X," A STRIKING EXAMPLE OF SPEEDY LINES.
Exhibited by Smith & Mabley Mfg. Co., New York City.

the proper temperature from the exhaust, the carbureter's function being merely that of spraying the fuel preparatory to vaporizing it. In this engine, electrical ignition is employed, but in another designed to use kerosene also, the incandescent system is used, an ingenious method of timing the explosion being arranged by means of an adjustable ignitor which may be raised or lowered while the engine is running.

Reverse Gears and Clutches.

Prominent among the new things to be found in this field was "Joe's Gear," made by the Snow & Petrelli Manufacturing Company, New Haven, Conn. It is of the spur type, the pinions being of hardened high-grade steel, accurately cut, and running in an oil-tight case. They are only in operation on the reverse, the device revolving solidly when going ahead. The complete gear itself is extremely simple and compact, and may be applied directly to the engine shaft, making alignment easy and positive. This concern also makes marine friction clutches, which are sold independently of the gears, as well as a line of yacht cannon and brass fittings. The well-known Gies gear, made by the Gies Gear Company, Detroit, Mich., and which has been on the market so long as to scarcely need description, as well as the Perfection gear, made by the Perfection Reversing Gear and Supply Company, New York, were also shown. The latter is of the constant mesh type, both the forward and reverse drives being made through a special expanding ring friction clutch.

A GENERAL VIEW OF BEAUTIFUL NASSAU HARBOR DURING THE RECENT MOTOR BOAT CARNIVAL.

THAT "FLAG-TO-FLAG" BOAT RACE.

According to official news which comes from Miami, Fla., the Race Committee of the "Flag-to-Flag" motor boat race, Miami to Nassau, has officially declared the *Whiz*, of New Haven, Captain Norton, winner in the power boat class, and the *Daggett*, of Miami, Captain Haggerty, winner in the auxiliary yacht class. Second in the classes respectively were the *Lee S.*, of Jacksonville, and the *Klondike*, of Miami. The auxiliary *Muriel*, of Miami, chartered by several members of the New York Motor Club, which started ahead of the other racers and then claimed the contest, was disqualified. On the return trip from Nassau to Miami the boats had a lively run across the Gulf Stream, the *Daggett's* engine breaking down on the homeward journey and the *Lee S.* being required to lend a helping hand.

In a letter received from W. J. Morgan the story is told of the exciting trip of the *Muriel*, and the tale is related in the characteristic manner of the "Senator." It is herewith given:

"We certainly had a frightful trip on the *Muriel* in the Flag-to-Flag race. This 55-foot auxiliary we chartered from some Nassau people who don't know any more about navigation than I do, so the result was that it nearly fell to the lot of the editor of THE AUTOMOBILE to write some touching obituary of 'Jonah,' the 'Flash-in-the-Pan Brothers,' and yours truly. Three others, including Commodore Allen, of Daytona, and Mr. Bell and his wife, made up the chump party who trusted their lives to the green sailors. The *Muriel* had plenty of sail and a 10-horsepower motor. The motor refused to mope before we got out of Biscayne Bay, but the sails carried us across the Gulf Stream in good shape. We only went thirty miles out of our course in a forty-five-mile run. The 'navigator' blamed it upon the compass, and said the motor probably had magnetized it. If that was so, it was the only thing the motor did. At night we anchored off a bleak-looking island without a sign of life on it or even a shrub, but which had the high-sounding name of Orange Key, probably because no oranges will ever grow on it. Our experienced sailors anchored within 400 yards of this leeward shore, a thing which Commodore Allen advised me proved that they were no sailors; but you see they were running the boat and we were having a run for our lives. I had been battling with Old Neptune most of the day and he had slightly the best of it, so that after sniffing at the supper, I turned in at about 6:30.

"At 8 o'clock Spooner woke me with a cry that our anchors were dragging and that we were nearly on the rocks. Upon which I heard the surf break with a roar, when I clambered

on deck with most of my clothes off, which Allen did also. If I live to be a thousand, I do not believe I ever will forget the terror of the moment as I looked at the breakers about 100 feet away and saw that our boat was slowly moving towards them. We got hold of the anchor chains and pulled for dear lives—Wetmore, Spooner, Lazarnick and Allen. We lay on the deck, pulling for our lives, and let me tell you there was not a coward among them. I thought of home, but did not fear what I thought was the final end. The anchor stuck, and I suggested to Allen that it be cut away. The crew by this time had become useless and panic stricken. Allen roared, 'Cut away those anchors or in five minutes we will be on the rocks!' Here again trouble came. The small anchor had fouled the larger one, so that they could not be run out by their chains through the hawser holes. Fortunately one of the anchors had a rope, which one of the sailors cut, and with a rattle the big chain and the rope went swishing to the bottom. At that moment a merciful wind caught the jib sail, and, as the spray was being felt on our faces from the breakers, the boat stood off from the rocks. We drifted all night, not knowing where, with no anchors, but the morning showed us that we had made no gain or loss. We fortunately anchored safely, after borrowing an anchor from a sponge vessel, and eventually arrived at Nassau, Thursday noon, being three days in crossing the 150 miles between the flags.

"We had quite an exciting experience the third day out from

GENERAL VIEW OF TOWN SHOWING GOVERNOR'S PALACE

TROPICAL "SALT CAY," OWNED BY ABRAM VAN WINKLE.

Miami. We came across a stranded whale sixty-five feet long, which we tried to capture. We forgot all about the race and drew our boat alongside of the monster. We used a shotgun and revolvers and also a long knife tied to an oar. We started him going to deep water and for our pains we ran on a bar. No liquor sold there. We did not do the fish much damage, but Spooner and Lazarnick got twelve pictures each.

"We claimed the first prize for the reason that we reached Nassau first, and it seems that it came about because the others did not start until Thursday and we began our foolish trip on Tuesday. On that morning we got away one hour late and thought all the rest had gone, for the reason that we could not get in close enough to the starting point to see if this was actually so. But as the rule said the start was to be at 7:05 A.M., we made up our minds that we were one hour late. So we went on our way to the first control, which we never reached. We now claim the prize for being d—n fools and vote each of ourselves a medal for doing something which the wise ones refused to do. If you ever catch me on a cockleshell boat with land-lubbers for navigators you will please pin a rose on me."

IN 1906 THERE WERE 1,267 CARS IMPORTED.

During the year 1906, according to the official reports, 1,267 foreign cars were brought into this country, 874 of which were imported by dealers and 393 brought in by individuals. The Hol-Tan Company led all other importers, selling 155 cars in this country. The next nearest total was that of Panhard, though three firms imported them. In grand totals the Mercedes led with 208 cars, Panhards second with 203, Renault third with 162, and Fiat fourth with 159. The following table tells its own story:

Car.	By Importers.	By Individuals.	Total.
Fiat	155	4	159
Panhard	125	78	203
Mercedes	98	110	208
Rochet-Schnelder	56	2	58

FOR NATIONAL AID IN ROAD BUILDING.

WASHINGTON, D. C., Feb. 25.—A notable good roads speech was made in the House of Representatives this week by Representative Flood, of Virginia, during the course of which he submitted a few reasons why he thought the Government should aid in the building of public roads throughout the country. The following excerpts from his address are of more than passing interest to the automobilists of the country:

"I think, undoubtedly, the power of the Government to make appropriations for the purpose of building roads is ample and can be defended. The power is expressly given to Congress by the Constitution 'to provide for the general welfare,' and the general welfare of this country demands at this time nothing so imperatively as it does a good system of public roads—a thing which we can never have without the aid of the Federal Government. The exercise of this power to aid in the building of public highways is more than 100 years old.

"There is no real distinction between a turnpike and a railroad in their claims for help from the general government. But the railroads have been aided to the extent of millions and millions of dollars in land and money by the national government, while the proposition to secure aid for the highways of the country meets with no favor beyond a respectful hearing. There is no real distinction, so far as the public good and welfare is concerned, between the aiding of public roads and the aiding of waterways, and yet our waterways and harbors have been aided to so colossal an extent as to dwarf and finally eclipse our equally valuable highways. The importance of good roads is so apparent it will not be questioned by one and need not be discussed.

"We are appropriating this year \$83,000,000 for rivers and harbors, \$95,000,000 for our naval establishment, and \$81,500,000 for the army. The building of a comprehensive system of good roads is of more importance to the people of this country than any one or all of these purposes. The necessity for better roads in many parts of this country is the greatest need of the hour. The States and counties cannot build them. The right kind of roads can only be built, and will only be built, when the national government lends a helping hand. If we are ever to have a system of roads in this country to compare with those of the other enlightened nations of the world, it has got to be done by the aid of the Federal Government.

"All the progressive countries of Europe are giving national aid to their highways, while our government is following the example of the South American nations. What a different picture has been presented by the countries of Europe. A splendid system of roads has been inaugurated by those countries. The great Napoleon, following the example set by the Roman Empire, built an extensive system of roads throughout France, and now not less than \$7,000,000 each year are expended by the French government in keeping up these roads and making new roads. The central government of England began to improve the roads in that country in 1835, and now \$15,000,000 is being expended yearly upon their roads.

"While this country has advanced in area, in population and in wealth, and along all lines of science, trade and industry, no advancement has been made in the condition of our roads in many sections of the country during the past one hundred years. Let the general government foster this great enterprise, not only at the behest of justice but of wisdom."

ROAD BUILDERS' CONVENTION, MARCH 12-14.

James H. MacDonald, president of the American Road Makers' Association, says that the road builders' convention, which is to be held in Pittsburg on March 12, 13 and 14, promises to be the largest meeting of the kind ever held in this country. He says the purpose of the convention will be to unite in one big meeting all the scientific road building interests of the United States, "each commissioner to relate to the convention work that has been done and to be done in his State."

A CRUCIAL TEST OF MODERN ALLOY STEEL

By THOS. J. FAY, E.E.

Of the several grades of steel likely to be found in automobile work, but few of them will be found to possess the characteristics most to be desired, *i.e.*, the ability to withstand shock without rupturing. It is scarcely to be expected that any automobile should be collision-proof, and deformation, as a result of a collision, is a reasonable expectation; but there is a great difference as between deformation and actual rupture of parts such as may sustain direct impact. In a testing machine

shock, or alternate stresses, are cars with a high price tag, and it is extremely difficult, in the abstract, to tell just why one car should cost double the price of another car, if both have the same power, same weight and same capacity for passengers or burden, as the case may be.

There may be some chance for misunderstanding in relation to this matter in that some may think the ability of steel to sustain shock loads is limited to "alloy" steel, as nickel, chrome-nickel, or chrome-wolfram steel. Such a view would be fallacious in the abstract, at any rate, since all grades, or better yet, kinds, of steel are more or less possessed of this ability, depending upon (a) purity, (b) process of manufacture, (c) extent to which the product is worked, (d) skill in treatment, not to mention numerous details of more or less moment, attending the process. The great question at the present time is to bring about a more complete realization of the fact that shock ability is a much desired quality, conspicuous for its absence in much of the steel to be had at every hand.

The old wagonmaker, in his day, had the right idea, although no ready means is at hand to indicate the process by which the wagonmaker hit upon the right idea. For all anyone can tell, the process was by way of repeated failures. In any case, wagonmakers use iron and steel of a quality that *does show great ability to sustain shock loads*. and, in the case of the wagonmaker, "alloy steel" is as a foreign language to a Kentucky colonel, but the carbon is kept very low in the wagonmaker's product and the elongation is high. Of course, such steel has not a high tensile value, nor would it serve for certain parts of motor cars; hence the need of alloy steel for them; but, whether the steel is alloyed or not, it should be rated, as before stated, on a basis of its ability to sustain shock loads, without showing rupture, *even though it may deform*.

FIG. 1.—How the 60-H.P. Mercedes looked after the smash.

"proofs" are pulled until rupture takes place, and the conventional physical properties are noted; or under a "tup" proofs are subjected to repeated blows until rupture takes place, unless perchance the proof is so tenacious as to bend so much that the test must be interrupted on that account. In the "pull test" the ability of steel to withstand shock is scarcely disclosed at all, while, on the other hand, the "tup" test is a fair indication of the shock ability of steel; but it is rarely that shock tests are published, if indeed they are made, except at rare intervals.

Why Shock Tests Are Not Made.

The probable reason why shock tests are neglected is owing to the fact that steel, high in tensile value, for any given *genera* is not likely to show up well in the "tup" test, and strange at it may seem, "beautiful women use the mirror most," so to speak. On the other hand, buyers of steel cry for high tensile values, and overlook the question of shock ability, whereas steel mongers "do the diplomatic" and furnish what is demanded, or what is most in demand, at any rate. The cars that are constructed of materials, such as are known to be capable of sustaining

The Unusual Lesson of a Wreck.

Illustrative of what can be done by way of building cars that will sustain shocks without rupturing the members (although, as before stated, they may bend), Fig. 1 is offered as a fine example—an illustration so pertinent, in fact, as probably not to be duplicated. An inspection of this illustration will show in the foreground the twisted and distorted aggregation of what previously served as a 60-horsepower car—suitable for racing when stripped—of the regular Mercedes products. The photographs were taken directly after the accident that befell the

FIG. 2.—On the Vanderbilt Cup Course, where the Mercedes climbed the telegraph pole, continuing until it turned turtle.

car during a "trial spin" on the Vanderbilt course just before the last event. The car was going at a mile-a-minute gait in the hands of the B-L-M driver, and in turning to make a curve at full speed, the steering gear locked; ere the car could be righted, the telegraph pole, broken in half, as shown in Fig. 2, was struck, with the result that the car was piled up in a twisted and distorted mass, full one telegraph pole distance or spacing away, just as the photograph shows, excepting that some of the parts previously detached were thrown on the pile at the pole, distant from the broken pole hit by the car. Fortunately, neither of the occupants of the car was seriously injured, although they were precipitated headlong, and one of them made a flight—air line—of some 69 yards.

FIG. 3.—Section of Mercedes rear axle made of chrome nickel steel.

This, however, is beside the story, for the point to be made is that of all the parts in the car, nearly every one of which was deformed, *not one showed a sign of fracture*, excepting some slight damage to the motor—a fracture of the aluminum crankcase, which is to be expected in view of the properties of aluminum. The car was some three years old and ran in the first Vanderbilt race, thus adequately illustrating the fact that ample opportunity was afforded to induce "metal fatigue" long before the moment of the accident; that is, assuming "metal fatigue" would develop to any marked extent in steel so fine. The car was a 60-horsepower "Mercedes" in racing trim, and while the speed was not definitely known, it was believed that it was something like a mile in 58 seconds.

As regards the grades of material that make it possible to report such results, it will be understood a metallurgist could write a book and still have something to talk about. Lack of space forbids lengthy discussion. It will be sufficient to conclude with a statement of the shock ability of some of the steel used in this class of cars, which may be set down as follows:

Chassis frame of C460 Krupp steel, the ability of which may be given as follows:

Physical Properties Krupp.

T.S.	E.L.	Ex-2"	Cold bending test.
100,000 lbs.	72,000 lbs.	16 per cent.	180° and flatten down.

Minimum guarantee for plates.

Diameter of proof 0.5 inch.

Deflection by Shock Krupp.

Blow Deflection No.	inches.	Data.
1	0.79	Proof: 1.18"x1.18"x11.81"
2	1.42	Supports: 9.45" separated.
3	2.05	Weight of tup: 448 pounds.
4	2.52	Height of fall: 39.37 inches.
5	2.91	Specimen doubled after test without rupture.

This product was fully illustrated in THE AUTOMOBILE of February 7, 1907, page 277. The question of the best dimensions of side frames was not raised, and it might be well to refer to this matter at this time. Many side frame members are made 4 1-2" x 1 3-4" x 3-16" depth, width and thickness of plates, respectively. The writer is at present using dimensions as shown in Fig. 4, although it may be well to repeat that the writer uses E F 60-o Krupp chrome nickel steel, so that for C460 Krupp the thickness should be 5 m/m instead of 4 m/m for equal rigidity, and it is safe to say the difference in weight would increase one-fifth as a result.

No Ruptures Whatever Were Found.

Axles in the car of the subject were of E F 60-o Krupp chrome nickel steel, the section of the rear axle being as shown in Fig. 3. Of this material the writer has commented at length

in his writings, but the opportunity to comment upon the question of ability to withstand shock has been limited, because tests of a thorough order were not easily obtainable. The axles in the wrecked car, however, surely were given much abuse, and they did deform, but they did not rupture. In fact, it would be possible to straighten out and use them again, not forgetting to subject them to an annealing process, of course. The shock ability of this particular steel is given by Krupp as follows:

Deflection by Shock Krupp.

Blow Deflection No.	in inches.	Data.
1	0.71	Proof: 1.18"x1.18"x11.81"
2	1.30	Supports: 9.45" separated.
3	1.89	Weight of tup: 448 pounds.
4	2.40	Height of fall: 39.37 inches.
5	2.80	Specimen doubled after test without rupture.

This product performs in a manner superior to C46-o Krupp steel, as a comparison of the shock tests will show, and knowing how well the axles served in practice, it is easy to fix upon a standard to go by, since the shock ability of this product is given in very precise terms. The distance rods, jackshaft, driving shaft, crankshaft, gears, and like parts, having the greatest loads to sustain are of this same steel, as indeed they should be, since some of these parts do far more work than the axles. As to why this steel so ably sustains shock loads, a word may be in order, particularly in view of the fact that it is not merely because the steel is an "alloy" product.

With a view to discussing the matter in a clear manner, the chemical composition will have to be restated, viz.: E F 60-o Krupp.

Chemical Composition Hunt.

Chromium	1.40	per cent
Nickel	3.31	" "
Carbon	0.31	" "
Silicon	0.20	" "
Sulfur	0.028	" "
Phosphorus	0.013	" "
Manganese	0.41	" "

As will be plainly seen, the phosphorus component is very low, and the sulfur is comparatively low as well, whereas the manganese is held at a moderate value. On the other hand, the high strength is not due to high carbon, nor can manganese be said to influence the strength in this instance, and so it is rational to conclude that pure metal, very low in the carbides, is rendered serviceable by the excellence of the relation between chromium, nickel and carbon, all of which is amply borne out, not only by the facts, but by the deductions that follow the tests in the conventional way, one of which tests by Hunt, at the instance of the writer, was as follows:

Physical Properties E. F. 60-o Krupp.

T.S.	E.L.	Ex-8"	Con.
109,100	81,400	23	61.8

This test is somewhat at variance with Krupp's figures, but the elongation checks up very well indeed.

FIG. 4.—Section of side frame of chrome nickel steel.

Just how dirt and other foreign matter finds its way into the inner recesses of the carburetor is something that even those most familiar with such matters find difficult to explain, except by the statement that such things do get there and that is all there is to it. This being the case, the necessity for constant vigilance regarding the fuel itself, as well as occasional inspection, is apparent.

SOURCES OF ELECTRIC IGNITION CURRENT

By CHARLES B. HAYWARD.

If it were possible to calculate the percentage of breakdowns in ignition systems that are directly traceable to each essential part, so that it could be said with any degree of certainty that the plugs failed so many times out of a hundred, the wiring so many and so on in the case of each part, such as the timer, switch and others, until the source of current was reached, it

FIG. 1.—Section of dry cell.

would be found that the latter generally proves to be a most prolific creator of failures. This was the case to a very great extent in the heyday of the dry cell, the percentage of failures from this cause having been very materially reduced by the adoption of accumulators and the improvement in mechanical generators. Considered from the point of view of the electrical engineer, the problem presented by the necessities of the ignition system of an automobile is positively childish in its simplicity. Taken fundamentally, it means nothing more difficult than the maintenance of a current of one or two amperes at a pressure of six to eight volts; the remainder is merely a question of providing simple and easily cared for apparatus, requiring no particular skill for its proper maintenance. As a matter of fact, modern coils and timers run on considerably less than this—or about 1-2 to 3-4 of an ampere at 6 volts, or slightly less in the case of accumulators after they have been in use some time.

The Old Story of Theory and Practice.

But like so many other things, this has proved to be but another instance where theory and practice have been found to disagree so radically that for a long time it seemed to be impossible to ever reconcile them. For the purposes of this article, sources of electric current may be divided into two classes, chemical and mechanical, the former including batteries of every kind, and the latter generators, such as small dynamos or the magneto. Merely to complete the list, the thermopile may be mentioned, this being a device by means of which electricity is produced directly from heat, but as it has never been brought beyond the laboratory stage, it need not be considered further, although an attempt has been made to use it for ignition purposes, employing the exhaust as the source of heat. For reasons that will at once be evident, the dry cell was selected in the first instance as the best available form of current producer. It combined cleanliness and portability with cheapness and ease of replacement, and a set of five or six cells seemed to provide all that could be desired. They produced a current at 10 to 15 amperes at 6 to 7 volts, so that, theoretically at least, they fulfilled the requirements. But pioneer automobile builders had much to learn of the peculiarities of the dry cell, and it is easy to see that progress might have been much more rapid in those first years had not many of the vagaries of the battery been attributed to the engine.

Characteristics of the Dry Cell.

As is commonly known, the dry cell is such only in name, the active solution being held by some absorbent material such as sawdust, paste or the like. Before going further, it may be explained that every battery consists of three essential elements, a negative and a positive plate or element and the exciting solution. The so-called dry cell consists of a carbon negative element in the shape of a plate and a zinc positive element, usually made in the shape of a containing case. The exciting solution is made of sal-ammoniac and water, in the proportion of about a pound of the former to half a gallon of water, the solution recrystallizing

if made too strong. Sawdust or special mixtures of paste are usually used to absorb it, and this is then packed between the two elements, the carbon plate being surrounded by a quantity of manganese dioxide or other depolarizing substance. In the generation of electricity by chemical means, hydrogen gas is always evolved. It is created at the positive element—the zinc in this case, and passes directly to the negative element. These terms are apt to be found somewhat confusing, as the positive element—the zinc—provides the negative terminal of the cell, and the carbon the positive terminal, though it is the negative element. The activity of the cell depends upon the rapidity with which hydrogen is evolved, but its continued working depends entirely upon how fast the gas is gotten rid of. As it comes from the positive element it passes across and the bubbles attach themselves to the negative element, insulating it from the action of the exciting fluid. When the surface of the negative element becomes entirely covered with bubbles of hydrogen, the cell is said to be polarized and its activity is seriously impaired; it seems to be dead. To overcome this to as great an extent as possible, substances having a high affinity for hydrogen are employed, which accounts for the use of manganese dioxide or similar material in the dry cell. This absorbs a large proportion of the hydrogen and greatly prolongs the active period of which the cell is capable. The dry cell is technically known as open-circuit; that is, it does not develop any energy except when called upon to do so by closing the circuit. As soon as the circuit is broken the production of hydrogen ceases and what has already been generated passes out through vent holes left in the pitch sealing at the top of the cell. It is then ready for active work again; this is generally termed recuperation, and it is the peculiarity of the dry cell that caused pioneer builders of cars untold trouble.

Early Experimenters Were Greatly Puzzled.

By reason of the fact that its excitant is not in a liquid form and consequently cannot circulate freely between the elements, the dry cell does not show the same degree of efficiency as a liquid cell of the same kind. Furthermore, it deteriorates steadily with age owing to the evaporation of the solution from the absorbent material, which cannot be totally prevented owing to the necessity for providing vents for the escape of the hydrogen. Given a perfectly fresh cell that will show 1 1-2 volts and 15 to 20 amperes on test, and place it on a short circuit for ten minutes, at the end of that time it will have scarcely enough life left to move the needle of the instrument. Tested two minutes later, it will show a surprising renewal of activity, and at the end of five or six minutes' rest will give practically the same indication as if it had not been allowed to run down. This may be repeated quite a number of times, the cell showing the same surprisingly rapid recuperation in each instance, until it begins to be exhausted by reason of the consumption of the active element of the exciting solution or by drying out. This was at the bottom of the early experimenter's troubles that were, in very many instances, laid to something else. The dry cell of that day was

FIG. 2.—Accumulator plates.

FIG. 3.—Magnetic field round a straight bar magnet

a long way from the high state of efficiency to which it has been brought in the meantime, and after the engine had been run a short time the cells no longer produced sufficient current to spark it. As they were all right not long before they were seldom suspected, and other parts of the mechanism were examined for trouble. Nothing appearing, that solace in times of perplexity—the crank—would be twisted and the battery having recovered in the meantime, the motor would start without further trouble.

Performances of this kind were repeated for a long while before the true cause of the trouble became established beyond a doubt, and then other means were resorted to, in many cases with even less success, but of these more later. In the end it was found that the dry cell, while suitable for use with single and two-cylinder engines, particularly of the slow speed horizontal types to which so much attention was devoted in this country in the early days of the industry, it was not capable of withstanding the draft made upon it by the high-speed four-cylinder engine and, though the dry cell has been vastly improved in the past few years, its use is not extended on multi-cylinder, high-speed engines, except possibly as an emergency. The dry cell is still used very largely on one and two-cylinder cars and on small motor boats. Much of the difficulty experienced with it in early days was due to the crude nature of the timing devices employed, which, in many instances, were designed to give a contact of much longer duration than was necessary to accomplish the end desired. This and other drawbacks of the apparatus that the first builders found themselves compelled to use, such as coils of very low efficiency, all combined to waste the life of the dry cell and the latter was blamed. When the high-speed, four-cylinder engine came into vogue it soon became apparent that, even at normal speed, the number of contacts per minute was so great as to constitute an almost continuous draft on the battery, a service for which the dry cell is not fitted.

Other Chemical Sources of Current.

There are numerous other methods of producing an electric current by chemical means, all of which are generally classed as primary batteries, as the current is generated directly from the action of chemicals on metals, but they are all open to the same objections as the dry cell, beside which they have other disadvantages, such as high first cost, noxious character of the solutions employed, and the like. Suffice it to say, no attempt has ever been made to utilize them for automobile work. This narrows the

FIG. 4.—Illustrating principle of the electro-magnet.

field of chemical current producers down to the dry cell and the accumulator. The latter is the result of many years of experimenting and investigation and forms a subject that cannot be treated at sufficient length under this heading, so that merely an outline of its characteristics will be given here, and a chapter devoted to it later. All storage batteries are classed as secondary cells because an electric current must first be passed through them. They do not generate electricity as does a primary cell. In the popular sense, they store electricity which may again be drawn forth when required, but, as a matter of fact, the process is wholly one of chemical conversion and reconversion, the current passed through them in the first instance constituting the excitant. Early types of storage batteries were, in fact, made in this way. The lead plates which constitute the elements were scored or nicked and placed directly in the acid solution; they were then "formed" by passing and re-passing a current through them in different directions until a sufficiently heavy deposit of the required chemicals made their appearance on the plates. Modern accumulators are made with cast lead grids, much ingenuity being displayed in the design of the latter by various manufacturers.

As is the case with a primary cell, an accumulator consists of a positive and negative element and an exciting solution, usually termed the electrolyte. Any cell which is capable of regeneration after exhaustion by passing an electric current through it is an accumulator, but as the lead plate type is the only one in general commercial use it alone will be considered. The positive elements consist of peroxide of lead and the negative of metallic

FIG. 5.—Magnetic field of a magneto.

FIG. 6.—Magnetic circuit and lines of force.

lead in a spongy form so as to be pervious to the electrolyte, which is a dilute solution of sulphuric acid and water. The plates can be readily distinguished by their colors, the positive plate being a chocolate shade while the negative is a light gray. It is also easy to distinguish them by their number, as there is always one more negative than positive plates. Under modern methods these plates are made in the form of grids containing recesses or pockets into which the chemicals are pasted or pressed forcibly, so that they will not shake loose nor disintegrate owing to the action of the cell. Briefly expressed, the theory of the accumulator is about as follows: when the battery is discharging the current passing through it decomposes the water of the electrolyte, forming hydrogen and oxygen, the former at the positive plate and the latter at the negative. These gases again recombine to form water to a small extent, the oxidization for the most part, however, resulting in the formation of lead sulphate. As this substance is practically an insulator, it is evident that discharging a cell until its elements were converted into lead sulphate would render it absolutely worthless. There is, in consequence, a limit beyond which a cell should not be discharged. Up to this point the formation of lead sulphate is small enough to be negligible, the resistance of the cell not being unduly raised, thus permitting the passage of the recharging current and the reconversion of the elements and electrolyte to their original form, there naturally always being a

FIG. 7.—Magnetic circuit after inserting armature.

FIG. 8.—Position of maximum induction.

slight loss every time this takes place. Both the theory and practice of the accumulator with regard to ignition needs will be taken up at greater length in a subsequent article, an attempt being made to clear up those points upon which questions are most frequently asked by the uninitiated.

Mechanical Forms of Generators.

It seems strange at first sight that the average layman should accept the generation of electricity by chemical means as a fact not to be wondered at, and still regard its production by purely mechanical means as a mystery beyond his comprehension. The principles underlying the subject are few and readily understood when taken in connection with the facts concerning the characteristics of electric currents, already explained at some length. Magnetism and electricity are manifestations of an unknown force that are very closely related; whether they are in fact one and the same has not been established to a certainty. For our purpose, it will suffice to say that they are interchangeable quantities, though magnetism is producible by means other than an electric current directly applied. Probably the most familiar form of the magnet is the horseshoe-shaped toy of schoolboy days that would pick up some pins and not others, simply because they were brass, and that had such an odd effect on the needle of a pocket compass. This was because the needle was itself a magnet, and its action was merely an illustration of the fundamental principle that opposite poles attract and like poles repel one another, every magnet consisting of a north and south pole. When the north pole of the magnet was brought close to the northwardly pointing end of the needle, the latter swung quickly away on its pivot, but when the north pole of the magnet was placed close to the south pole of the needle they attracted one another and remained stationary at the point at which the magnet was held.

The action of this invisible and mysterious power is most readily explained by a very simple experiment. Spread some fine iron filings on a thin sheet of glass or paper and then bring an ordinary magnet up against the underside of it; the particles of iron will immediately arrange themselves in symmetric lines radiating from each of the poles of the magnet, illustrating graphically the direction in which the force is exerted. These lines have been technically designated as lines of force. Many schoolboys wondered what the small piece of metal, usually termed the "keeper," that came with the magnet was for, and promptly proceeded to lose it or throw it away. In time that magnet became so weak that it traveled the same road. While these lines of force radiate in the manner shown, they also travel in a circuit the same as a current, and if there be a gap between the poles much of the magnetism will be dissipated. It is commonly said to "leak away." Just what becomes of it is a mystery, but it is well known that unless the gap between the poles be occupied by some magnetic material such as iron or steel the magnet becomes weaker with age. This piece is technically termed an armature.

The first fundamental principle that illustrates the interchangeability, to so speak, of electricity and magnetism is the fact that if an electric current be passed through a wire wound about a piece of iron or steel the latter immediately becomes magnetic. In the former case this disappears as soon as the current stops, but in the latter a large part of the magnetism is retained, this being a property of steel that makes possible the manufacture of what are known as permanent magnets such as the toys referred to. On the other hand, if a magnet be brought close to a coil of wire or passed by or through it, an electric current is induced in the wire. This, in brief, represents the fundamental principles upon which the generation of electricity by mechanical means rests.

How These Principles Are Employed.

The manner in which these principles are taken advantage of practically is most easily explained by a reference to the magneto, as it is the simplest form of generator. Its two principal parts are known as the field and the armature, the former being illustrated by the sketch A. A compound magnet is used, one being placed over the other in order to increase the strength. The semi-circular blocks placed at the poles are termed pole pieces and are made in this form in order to closely embrace the armature which revolves between them. The direction of the so-called lines of force in such a combination are illustrated by B, and the manner in which the insertion of the armature affects them is shown at C. This armature in the great majority of magnetos is an H-shaped piece of soft cast iron, the recesses of which are filled with a winding of insulated copper wire. As shown at C, the armature is in what is termed the neutral position; the magnetic flux, or flow, is greatest but it is unimpeded and practically no current is generated; in other words, this is a dead point. The direction of the magnetic flux is indicated by the arrow, which also shows the direction in which the armature is revolved, that is, to the right, or clockwise. As shown at D, the armature has been given a quarter turn; although the magnetic flux is indicated as accommodating itself to the changed position of the armature, the latter is in reality cutting the lines of force, and at this point the current flow is at the maximum, starting when the edge of the armature first rises above the pole pieces, increasing until it is in the position shown at D and subsiding in the same ratio as it continues to turn, until it is again at a neutral or dead point, as shown at E. The same process is then repeated as the armature is revolved through the second half of its revolution. At F it is again shown cutting the greatest possible number of the magnetic lines of force and the current induced is again at a maximum, but the polarity of the magnet represented by the armature having reversed its relation to the polarity of the permanent magnet, the direction of the induced current is also reversed, so that the output of the machine is what is known as an alternating current. The passage of the armature past the maximum point shown at D induces a pulsation of current in one direction and,

FIG. 9.—Electric "dead center" of the magneto.

FIG. 10.—Second position of maximum induction.

as shown at F, in the opposite direction. To illustrate the principle that like magnetic poles repel and opposite poles attract, it may be assumed that a current is sent through the magneto and it is run as a motor. If the current were switched on with the armature shown in the position at C, it would not start revolving, as it is at what may be termed a magnetic dead center. But if given a quarter turn, as shown at D, it would immediately begin to turn. The north pole of the armature would repel that of the field and in moving away from it would come within the influence of the south pole of the field and be attracted, the same process going on at the other poles. If the current were sent through it in the other direction the polarity of the armature would be reversed, the upper end of it, as shown at D, then becoming south and attracting the north pole of the field so that the armature would begin to revolve toward the left. This also illustrates the interchangeability of most forms of current producers, in that when revolved mechanically they generate an electric current, and when the latter is sent through them they convert it into mechanical energy.

The dynamo or direct current generator is somewhat more complicated in that both its field and armature are electro-magnets. Both are wound with coils of wire and the current induced in each depends entirely upon the number of turns and the speed at which the armature is revolved, the latter of which reasons accounts for the fact that it is usually more difficult to start a motor when a dynamo is used for generating the ignition current than where a magneto is used. In the dynamo, also, the current generated is alternating, but it is converted into a direct current by the commutator. Both of these forms of current generating apparatus will be dealt with at length separately. The next part of this article will deal with the accumulator more in detail.

WHY THE ENGINEERS MEET IN INDIANA.

INDIANAPOLIS, IND., Feb. 25.—The semi-annual meeting of the American Society of Mechanical Engineers will be held in this city. The date of the meeting will be from May 28 to 30. One reason for choosing Indianapolis as the meeting place was that it has seven large automobile factories, with 18 additional factories in cities and towns adjoining. The number that will attend is variously estimated at from 500 to 800 persons, although the membership numbers almost 2,500 persons. On Thursday evening the banquet and reception will be given, and on Friday the visitors will be the guests of Purdue University, at Lafayette, where there are elaborate mechanical laboratories and an automobile testing plant.

All sessions will be held in the Claypool Hotel. E. R. Whittemore is chairman of the local committee on arrangements, and on the subcommittees the following chairmen have been named: Entertainment of visiting women, W. E. Sharpe; hotels, W. G. Wall, of the National Motor Vehicle Company; finance, L. M. Wainwright, of the Diamond Chain Manufacturing Company; entertainment, H. H. Rtee, of the Pope Motor Car Company, and printing and press, Theodore Weinsbank.

MANY AUTO STAGE LINES IN SOUTHWEST.

AMARILLO, TEX., Feb. 25.—Plans are now being made, which it is very evident will be fulfilled, for an auto line between Amarillo, Tex., and Tuseumcari, N. M. A. R. Carter, of Tuseumcari, has been in the city several times lately and has just gone over the route proposed for the line in an Orient buckboard, making a survey for the route of the line. The auto trip will be made over the route of the unfinished Choctaw extension west. There are few difficulties in the shape of bad and rough ground on the line proposed, and the promoters claim that the demand, both on account of passenger service and mail, will amply pay for the line. So far as can be learned, no machines have been purchased yet, nor is it known just what particular make is favored, but it is understood that a well-known American car will be employed.

AN EXPLANATION OF GRADE PERCENTAGES.

It is evident from the number of questions that continually crop up on the subject of grade percentages that little has been done toward removing the popular impression that a grade of 100 per cent. represents infinity, or a perpendicular line, despite the frequency with which the matter has been explained. There are two ways of stating the rise of a gradient, either in relative travel, which is more commonly used abroad than in this country, and in terms of percentage. The basic principle underlying either is the same, but it will doubtless be conceded that the English method conveys a better idea to the lay mind than does a percentage, particularly as the point upon which the greatest amount of ignorance exists is that upon which the percentage is calculated. The method of calculating grades generally used by civil engineers is graphically explained by the accompanying sketch. This represents a right-angled isosceles triangle, the base of which represents distance traveled horizontally and the upright side, distance traveled perpendicularly, while the sloping lines illustrate various grades.

If it be assumed that the base of the triangle represents a line 1,000 feet long and that the first sloping line represents a road

ILLUSTRATING METHOD OF CALCULATING GRADE PERCENTAGES.

having a rise that brings it 125 feet above the starting point, this is figured as 125 feet in a thousand, or 12 1/2 per cent. In other words, one foot of rise for every eight feet, but the latter distance does not mean distance actually traveled by a car in ascending such a slope, but distance measured horizontally with reference to that slope. The grade is measured by the tangent of the angle of inclination and not by its sine, so that a grade which represents 100 per cent. corresponds to an angle of inclination of but 45 degrees, and not 90 degrees, or perpendicular, as is commonly supposed. At the upper end of the next sloping line the elevation would amount to 250 feet, which is equivalent to a rise of one foot for every four feet traveled horizontally. So one in three corresponds to a 33 1/3 per cent. grade, one in two, to a 50 per cent. grade, and so on until a 100 per cent. grade is reached, which, as noted, is the equivalent of a 45 degree angle.

Closely connected with this is the question of how steep a grade can be overcome by a car, but as must be apparent it is one involving more than one factor, though in the end the chief consideration is that of the force of gravity. The first question is that of traction, and given this essential by providing a good road surface, very steep hills can be climbed, but sooner or later a point is reached where gravity rises superior to all other forces.

KEEPING THE MUD UNDER CONTROL

MUD, like poverty, is always with us. Its total abolition does not yet appear to be within the range of possibility; much, however, can be done to diminish this unwelcome companion, and whatever efforts are made will always be welcomed by the automobilist. One of the leading French body builders has given the results of his experiments in this direction in the columns of *La Vie Automobile*. The splashing of an automobile may be due to either its own wheels or those of other vehicles passing it on the road. Generally the automobilist is content to protect his own vehicle and is little concerned if his devices have as result the throwing of a stream of mud on foot passengers or other automobiles. There is no reason, however, why he should not only protect himself and at the same time prevent his mud striking his neighbors.

Mud splashes from the rear wheels are easily dealt with. Round mud guards, concentric with the wheel, or slightly eccentric, in order to increase the side entrance, practically resolve the question so far as the car is concerned. They do not, however, protect passers-by, and it is a pity that more attention is not paid to

FIG. 1.—How road users are splashed. A leather shield is the remedy.

this, for by carrying the mud guards further round and fixing a leather splasher loaded on its lower end, all inconvenience to other users of the road would be abolished. When the wheels are very far to the rear, or the body is short, it often happens that the guard is not inclosed by the body, and in this case it is neces-

FIG. 2.—An effective front guard. An ineffective front guard.

sary to inclose the interior of the guard by a shield. Round mud guards have the serious inconvenience of being in the way when attention has to be given to the tires. For this reason many automobilists prefer mud guards with a raised rear. To be effective this type of mud guard should extend beyond the rearmost portion of the wheel at least nine inches. Even then it will not prevent splashing of other users of the road.

The problem of the front wheel is more complex, owing to the mobility of the wheels which distribute their crown of mud in every direction within their angle of turn. The particles of mud carried up by these wheels are drawn from their surface by centrifugal force and thrown according to the tangent of the wheel at the point where they leave it. They are driven rearwards by the wind and finally sucked in different directions by the air currents formed by the car.

The passage of the mud can be considered under four distinct heads, according to whether it goes under the front guard, is stopped by the guard below the chassis, above the chassis, or passes in front of the mud guard. Considering the right front wheel only, for the principle is the same in the case of all the others, when mud passes under the front guard it is largely

thrown under the footboard if the car is running in a straight line. If the vehicle turns to the right it goes under the chassis; if it turns to the left it is thrown outwards. To stop this shower of mud all that is necessary in the majority of cases is a leather

FIG. 3.—This type of guard prevents all splashing.

splasher stiffened at its base. It is this column of mud which causes the most trouble, for it is increased by the splashing caused by the falling of the wheel into occasional pools of water. This splasher thus cuts the column at its base. If the car turns to the right the direction of the column should be under the chassis, but it is thrown back by the strong current of air constantly passing under the machine from front to rear, caused by the displacement of the radiator, the front mud guards and the lower portion of the wheels. This current escapes not only at the rear, but at the two sides between the wheels. Driven from under the chassis, the mud spreads out on the outer side of the guards, splashes on the sides of the car and finally falls on the footboard. To stop these projections the space between the footboard and the chassis should be entirely inclosed by a shield which should be clean-cut, make no noise and be easily dismountable. It may be either in metal or in leather, though the latter is not to be recommended on account of its tendency to crack after a certain length of time as a result of its proximity to the hot exhaust and its continual soaking in water. Metal, on the other hand, gives perfect satisfaction; as will be seen by the accompanying illus-

FIG. 4.—A shield between frame and footboard is clean and neat.

tration, it has the further advantage of hiding such inelegant organs as lubricating pipes, exhaust box and pipe, lower part of crankcase, etc.

If the automobile turns to the left, a column of mud is thrown outwards, but is again thrown back on the car by exterior air

currents. The mud splashing outside the action of the guards is thrown back on the body and spreads itself out on the rear mud guard, the panels and the footboard. To prevent this a 1 1/2-inch descending flange should be fixed along the entire outside edge of the front mud guard. All that has been said of the first column applies to the second, mud stopped by the guard below the chassis; for the third column—that in which the mud strikes the guard on its upper surface—it is advisable to inclose the interior of the guard by a metal shield which will completely protect the hood and the dashboard. Other projections will be stopped by the guard and its exterior border.

A final column has to be discussed, that which strikes the lamps and afterwards falls on the car. To get the best protection against this the guard should be entirely concentric to the wheel and be carried forward as far as possible. To obtain perfect protection against front and side splashes, carry the side flange forward, increasing its depth to the maximum with due allowance for the play of the wheel. When the front guards are carried far forward it may be necessary to specially shape them to accommodate the lamps. To lengthen the life of mud guards they should be mounted on the chassis, where they get the advantage of the springs, and never directly on the wheels. If fitted up in this way an automobile can face the muddiest roads, travel at a rapid rate and return to the garage without any other mud than that thrown up by passing vehicles.

HOW TO GRIND HIGH SPEED TOOLS.

FROM *THE MECHANICAL WORLD*.

High-speed steel tools can be ruined very easily in the machine shop by grinding them on the emery wheel until they get hot and then plunging them into water. After doing this, the cutting edge of the tools will be found full of cracks. An American writer cites the case of a machine foreman who complained that the tool dresser was cracking the tools in hardening, but a careful investigation showed that the tools had been cracked by grinding in this way. The man was instructed how to grind the high-speed tools properly, and that put an end to the trouble from cracks in the tools.

A NEW AND EFFECTIVE VALVE TOOL.

An improved method of dismounting and grinding automobile valves is made possible by the tool illustrated herewith. By its use any person can dismount a valve entirely unaided, and without fatigue, simplicity being one of the good features of the tool.

VALVE TOOL IN WORKING POSITION.

As shown in the illustration, the valve spring has been contracted by simply screwing down the screw bolt, and the cotter pin is about to be withdrawn. To use the same tool for grinding valves, a kind of screw-driver is inserted in the opening at the base of the tool and held in position by a set screw, the appliance being then used as a brace, and the valve ground with much more ease than by the usual methods.

The tool is a French invention, placed on the market by M. Etienne Baudot, 231 Boulevard Pereire, Paris. It has been well received by French chauffeurs, and is already in use in a large number of garages. Although specially designed for the typical type of French motor shown in the illustration, and not adapted to certain American engines, the tool is certain to be adopted in this country.

A FAMOUS PIONEER MANUFACTURER.

Leon Serpollet, whose death was announced in a recent number of *THE AUTOMOBILE*, at the age of forty-eight years, gave proof of mechanical genius when a youth of seventeen. At this early age he built, entirely unaided, a curious wooden tricycle. At the age of twenty-three he had devised his first steam automobile, and in order to more profitably work out his idea removed from his native town of Culoz to Paris. He rented a small workshop and labored diligently at his new machines.

His first motor-driven vehicle was a steam tricycle with which, in 1888, he traveled from Paris to St. Germain, a distance of about ten miles. It was a curious single-seated structure with the engine carried behind the driver and had an unfortunate habit of overturning when rounding corners. At that time automobilists were an unknown quantity, and when Ser-

SERPOLLET IN HIS PARIS FACTORY.

pollet made application to the authorities for a license to drive his vehicle on the public highway he had to wait two years for the document. The license is dated April 17, 1891, and is the first driving certificate issued by the French authorities. After the single-seated tricycle came a larger two-seated machine with wooden wheels and engine in the rear and under the body. The most famous voyage on this machine was from Paris to Lyons, accompanied by M. Ernest Archdeacon, of aeronautic fame. Serpollet caused a sensation at this time by climbing the Montmartre hill at Paris, which has a grade of 17 per cent. In 1889 his first four-seated steam automobile was built at the Peugeot factory, and was exposed at the Paris exposition of the same year. From this time his success was rapid. His engines were adopted by the Paris Omnibus Company, and the extent of his business increased enormously. Partnership was entered into with Frank Gardner, under the title of Gardner-Serpollet, with works at Paris. About this time Serpollet gained considerable notoriety as a speed champion. In 1893, with a steamer which was christened the *Easter Egg*, he was the first to attain a speed of 75 miles an hour. For three years in succession he held the Henri de Rothschild Cup for speed records on the Boulevard des Anglais at Nice. At the end of last year Serpollet united with M. Darracq, in a combination known as the Darracq-Serpollet Company. Plans were laid for doing business on a gigantic scale, and it is probable that the company would revolutionize public transport service in Europe. Just as the works were nearing completion and at the time when Serpollet's name was on everyone's lips, a short illness carried him off in the prime of his career. The funeral service was attended by a huge crowd of automobilists and the general public.

Rollin H. White cabled a message of sympathy to the family of the late Leon Serpollet. The two men were firm friends and had much in common, for M. Serpollet upheld the reputation of the steam car in France just as Mr. White did in America and other parts of the world. Both worked along the lines of entirely eliminating the boiler and both were successful, although accomplishing their ends in an entirely different way. The best indication that their respective inventions were in no way alike is afforded by the fact that Rollin White secured patents in France on his generator and the several regulating and auxiliary devices, without in any way coming in conflict with the Serpollet patents.

LETTERS INTERESTING AND INSTRUCTIVE

Value of the Auxiliary Exhaust.

Editor THE AUTOMOBILE:

[597].—As an automobile user, I like to keep closely in touch with everything pertaining to the motor-propelled conveyance, and one of the details of gasoline-engine construction, concerning which I have somewhat of a hobby, is the auxiliary exhaust port. I cannot see why this feature is not more widely applied, since it unquestionably helps the cooling materially, besides appreciably increasing power and conferring other advantages. And surely it is simple enough. I am now running a car that was originally built in accordance with standard ideas of design, but to which I afterwards had auxiliary exhausts provided. The results have been in every way most satisfactory, with the natural consequence that I am unable to see why the same idea should not be applied to every engine built—air or water-cooled. Surely, the modern automobile engine is not so perfect that even the least possible improvement can be disregarded.

OTTO LEPPANEN.

Cheyenne, Wyo.

There is no question but that the auxiliary exhaust possesses considerable merits, among which are the ones you enumerate, but, like everything else, it also has objections. For one thing, unless some special arrangement is made to prevent this, oil is likely to blow out through the auxiliary exhaust port, thus wasting the lubricant as well as fouling the exhaust passages. As for simplicity it is true that a plain opening in the cylinder wall is hardly to be condemned as objectionable, but what about the extra piping required to connect it up with the muffler? And what about the further fact that in its most successful form, as applied to a well-known American air-cooled car, it is not deemed expedient to use it without a poppet valve to control its action? Nevertheless, it is of undoubted advantage as an aid to air-cooling, and there is now at least one American water-cooled car to which it is regularly applied, though it has been tried and discarded by prominent makes in the past. One of its greatest advantages is the relief it affords the regular exhaust valve from the onerous duties ordinarily imposed upon it. Not only is the major portion of the cylinderful of hot gases let out through auxiliary opening—what is left is greatly cooled by the consequent expansion before it passes out by way of the normal exhaust valve. The value of this effect is well attested by the immunity from pitting and warping enjoyed by the exhaust valves of engines equipped with the auxiliary relief.

Dismountable Rims and Removable Rims.

Editor THE AUTOMOBILE:

[598].—Will you please tell me, through the columns of your interesting periodical, what, strictly speaking, should be understood by "removable rim." Insofar as I have observed, the term first came into use in this country immediately after the winning of the Grand Prix last year, by a Renault car equipped with a device allowing the removal and replacement of complete, inflated tires. Now, however, "removable rim" seems to be used indiscriminately, not only in the sense just referred to, but also to denote that class of constructions simply facilitating the removal of the tire by some system of mechanical dismounting. In "The Automobile," as well as in other periodicals, I note that advertisers of systems of mechanical tire attachment do not hesitate to refer to their devices as "removable rims," even going so far as to point a direct analogy in pictures and text, when no such analogy exists. Is this not unwise, as well as unfair to the less well-informed portion of the automobile-using public, and could not some sort of concerted action be taken to create a nomenclature dealing with this subject, which could be by no possibility misunderstood?

Reno, Nev.

CHRIS. ELKINSON.

There is, undoubtedly, more or less of the misunderstanding you refer to, and, of course, there may be occasional instances of mild misrepresentation founded upon an indefinite use of terms that lack to begin with any clear definition. But it is scarcely possible to force usage, so we all must be content to wait until the situation clears itself in a natural manner. Already there is a tendency to apply the term "dismountable rim" to the type permitting the manipulation of inflated tire units, leaving "removable rim" to the other construction.

A Motor "Down by the Head."

Editor THE AUTOMOBILE:

[599].—Was glad to see my letter (No. 538) published in "The Automobile" of January 24. In answer to your inquiries, would say that I am sure the first cylinder gets more oil, for the reason that the spark plug in the said cylinder is always foul. Just the other day I was troubled with this cylinder missing fire, and when I went to take the plug out I found that the oil had worked around the plug, and was even on top of the cylinder. There is no serious overheating, scoring of cylinders or seizing of pistons. The oil I have been using is Mobil Oil A. I have this trouble all the time, even on the level. I am not sure that I keep a high enough oil level in the crankcase. I always feed enough oil so that there is a slight smoke at the exhaust. Do you think it advisable to drill a small hole at the bottom of the crankcase partition?

JOSEPH O. THOMAS.

Raleigh, N. C.

There appears to be no doubt of the fact that there is constantly an excess of oil in the forward part of the crankcase, and as everything else seems to be in proper condition, the only logical conclusion possible under the circumstances is that the engine on your car has either not been properly leveled or something has happened to the car "to bring it down by the head," to use a nautical expression. Try a level on it and see if this is not the case, making the test both with the car empty and with the passengers aboard, as the weight of the latter may account for the difference if examination should prove the engine to be level with the car empty. If the forward part of the engine is lower than the rear end, drilling a hole through the crankcase partition will serve to equalize the level to a greater extent than is possible where the partition at present keeps most of the oil forward of it, but there will still be too much oil in the forward end. The best remedy will be to level the engine. The set of the springs may be at fault.

Data Wanted on Engine Testing.

Editor THE AUTOMOBILE:

[600].—As an occasional reader of your paper would it be asking too much of you to lend me a little assistance in the matter of obtaining data and formula which will give accurately the brake test and apparatus necessary to make same for an air-cooled single and four-cylinder engine. I have an experimental plant at my local address, and these are my first products. I am now desirous of obtaining an accurate estimate of the power developed by my engine, which is of the four-cycle type without any carburetor or mixing valve, only valve-inlet being used. These original features, together with numerous others on which I hold patents, give me a great advantage, and, I believe, much higher efficiency than the modern automobile engine. It only remains to find some adequate means of measuring this power. Can you suggest some A-1 text or handbook which gives in detail light on the subject of Prony brake tests?

Toronto, Ont.

A. G. RONAN.

While a great deal has been written on the subject of engine testing in the shape of monographs and magazine articles, so far as we have been able to ascertain, there is no hand or textbook on the subject extant. Practically every volume on the gas engine includes a chapter or two on this subject, such as "The Gas Engine," by Hutton, or the "Gas Engine Handbook," by E. W. Roberts. We should be pleased to learn the result of your tests.

The Geared-flywheel Idea.

Editor THE AUTOMOBILE:

[601].—With the present straining for lightness and efficiency in automobile engines, how does it happen that no one ever seems to think of applying a flywheel driven by multiplying gears off the crankshaft, instead of directly mounted upon it? It seems to me that the obvious advantages of a great balancing effect with a very light weight would be secured in this way, because by making the flywheel small and running it much faster than the engine, it would do all that could be done by a larger wheel. And, besides its smallness, it could be so raised above the crankshaft that it would have less of a tendency to reduce the road clear-

ance than is present with the ordinary construction. Of course, the complication would be slightly increased, but I cannot see why two simple gears and a couple of extra bearings should stand in the way of the other advantages. I understand that the flywheels of many of the best automobiles weigh 100 pounds or more, and certainly, anything ought to be desirable that would eliminate three-quarters of this or more, in this way adding just that much to carrying capacity.

H. H. WEBB.

Garden City, L. I.

Every fact that can be urged in favor of the geared flywheel, except one, is in favor of it. That one, however, is sufficient to condemn it. It has been proved again and again, by tests and experiments made by the ablest engineers, that it is impossible to make gearing so perfect that it will run smoothly and continue to run smoothly without backlash or lost motion. And when it is realized that 1-500 of an inch play between a flywheel and the shaft on which it is mounted will occasion all sorts of serious trouble, due to the frequent reversal of stresses, it can be understood that gearing interposed between the power-developing element and the balancing element is hopelessly impracticable. The best results have been secured with herringbone gears, but even with these no real success has been achieved.

How to Clean Out a Radiator.

Editor THE AUTOMOBILE:

[602.]—I have been trying to find an article on cleaning out radiators in the back numbers of "The Automobile," but do not recall the date, and have been unable to put my hand on the number. If I remember aright, the use of caustic soda was advised, but I do not know how strong a mixture to use nor how long to let it remain, so will you kindly let me know when the article in question appeared, or give me the information desired?

Morristown, N. J.

B. MARSTON SMITH.

We do not recall the article you mention and have not found any specific reference to caustic soda in anything that has appeared on the subject of cleaning radiators within the past few months. A ten to twenty per cent. solution could be employed, dissolving the soda in hot water, and it would not be apt to damage the metal by permitting it to remain several hours, or even over night. We should, however, recommend the use of what is known as a pickling solution as being much more convenient than soda. This is made of sulphuric acid, or what is usually known commercially as vitriol, the proportions being about the same, though a ten per cent. solution will doubtless be found strong enough for all purposes. Mix with cold water by pouring the acid into the water slowly, never the reverse. The two combine chemically and considerable heat is evolved; if the acid be poured into the water too fast there is danger of cracking the vessel, which should be glass or porcelain. Let the solution cool before using. The sulphuric acid immediately attacks the copper or brass of the radiator and will clean it in a comparatively short time. The best way to follow the progress of its action will be to draw some off from time to time, refilling with fresh solution. When it runs off clear the process is at an end. The radiator should then be flushed out very thoroughly so as to eliminate every trace of the acid.

More Light on the Ignition Proposition.

Editor THE AUTOMOBILE:

[603.]—With a multicylinder engine, is the current consumption in extra proportion to the number of cylinders—that is to say, does a four-cylinder engine use four times as much current as a one-cylinder engine, and does a six-cylinder engine use half as much again as a four-cylinder engine? It is assumed, of course, that the motors run at equal speeds. I cannot see any reason why the proportionate current consumption should not be as I have stated it, all factors other than the number of cylinders being equal, but several friends of mine who use multicylinder cars say that their observation does not indicate anything like a proportionate increase in the current consumption.

JOHN HAGEN.

Brooklyn, N. Y.

It is perfectly obvious that the current required to produce sparks at four plugs in a given time must be four times as great as that required to produce a spark at one plug in

the same time, the plugs being the same and all other factors being equal. Probably the explanation of the contrary opinion you have found lies in the fact that most multicylinder cars run with less gear changing than is required for single-cylinder cars, so that though there may be more current consumed during each revolution of the motor there are less revolutions of the motor to a given travel of the car. Take, for instance, the case of two cars climbing a grade. One, a car with a powerful multicylinder engine, will take the grade on the high gear, with the crankshaft revolving rather slowly. The other, weaker, with a single-cylinder engine, will have to drop to the lowest gear and climb with the motor turning over at such extreme speed that the single cylinder will require nearly as many ignition contacts per given time or distance as is required by all of the cylinders of the engine in the other car, during the same time or in going the same distance.

Distance Stanleys Ordered, But Not Delivered.

Editor THE AUTOMOBILE:

[604.]—I was glad to see in your issue of February 14 "How a Stanley Agent Feels About It." My back has been up for some time, and were I a Stanley agent I would have taken a fall out of someone long ago. Your paper, as well as the others, has never used the Stanleys fair in reporting the races entered by them. I and others believe this to be simply owing to the fact that they are not advertisers. In the races they have entered they have given odds, but never asked any; all their races have been won fairly, and always a light-powered car against a heavier one.

I had to smile to see Mr. Stanley at Mt. Washington two years ago in a fully equipped stock runabout—no freak—while the others were in overalls and grease and stripping their cars of every available ounce. He easily made the ascent in record time, taking Mrs. Stanley along with him, and she is no featherweight. I am proud to say I know the Stanleys well; their drivers, Marriott and Durbin, and their Ormond Beach racing rig. I would like to have someone tell me where the freak element comes in on this car, except in the shape of the windshield. The machinery is identical, except in size, to their regular output; the construction of engine, boiler and connections being the same. The shape of outside is odd but very practical, and Marriott probably owes his life to its light construction. Most reports of accident gave the impression that it was owing to a breakdown. As I understood it, a bad place in the course was to blame, Marriott took long chances at this particular spot, and none realized it as well as he did; but that was his job. It was a shame that while the laurel wreaths were flying around a year ago one of them did not hit him. The driver of the 200-horsepower foreign freak got it, but I am just Yankee enough to think it did not belong to him. They called him "Speed King," but he certainly sat in the second row.

They who think that Stanley cars are only fit for short dashes know very little of them; I see no reason why they should not enter even the Vanderbilt race with fair chance of winning. They would have to take water every fifty miles, but could easily spare the time—the advantage they would have getting away on the turns would more than make up for time lost in watering. There is no automobile made so easy on tires, and this would go a long way to help win. I hope to see one of these cars entered in a long distance race, and when it does I will wager there will be more come the cry-baby act than at Ormond. I am, of course, a Stanley owner, and most enthusiastic over my little rig that is always ready for a 500 to 1,000 mile run.

Portland, Me.

HENRY R. STICKNEY.

For the 1906 American Elimination trial of the Vanderbilt Cup race, Charles J. Swain and John N. Wilkins, Jr., two well-known members of the Cape May Automobile Club, placed orders, after consultation with F. O. Stanley, for two steam racing cars. Subsequently Secretary J. Hiscock, of the Cape May Automobile Club, made a thorough explanation of the entire matter, and it appears on page 297 of the September 6, 1906, issue of THE AUTOMOBILE. If the Stanleys can construct a long-distance racer there is no reason why they would not receive a commensurate amount of publicity. Up to date it remains a fact that two such racers were ordered and not delivered, and it is an additional fact that the cars were actually constructed, and apparently found unsatisfactory, for Messrs. Swain and Wilkins saw fit to make public a signed statement in reference to the non-delivery.

Fording Streams with Carbureter Submerged.

[605.]—We have occasion in this part of the country where very few of the streams are crossed by bridges to make more or less frequent fords, and, in some cases, the water is quite deep. I would like to have you tell me how a stream can be forded when the carbureter is under water. R. W. EATON.
Watsonville, Cal.

We very much fear that this is a case in which the suggestion of the small boy is most apt to be in order. "Git out and push." It is evident that if the water level reach a point where the carbureter is submerged totally, it must perforce cease operations and the motor will in turn do likewise. If you know the bottom of the river to be safe at the point in question—i. e., free from treacherous holes or rocks and the stream is not too wide—the expedient usually adopted in such cases may serve. That is, to rush the ford, trusting to the momentum gained while the engine continues to run to carry the car to the opposite bank. This is done quite frequently in the case of narrow streams.

REGARDING SALE OF RENAULTS IN AMERICA.

Editor THE AUTOMOBILE:

[606.]—Regarding the matter of Renault Freres representation in this country, I wish to make clear to the public through your valued publication that we, the Renault Freres Selling Branch, are the direct branch house of Renault Freres in this country and are the only authorized agents. I will go further and state that no other concern can buy any Renault cars direct from the factory—all Renault cars in this country have to be purchased from the Renault Freres Selling Branch, or its authorized agents, which are as follows: Cryder & Co., New York City; Palais de l'Automobile, 1778 Broadway, New York City (who have a contract with us both for 1907 and 1908); C. P. MacNamara, New York City; J. L. Keir, 310 North Broad street, Philadelphia; Pardee & Canary, 1218 Michigan avenue, Chicago; Quinby & Co., Newark, N. J.

I have noticed in several papers that the C. A. Tilston Company advertise themselves as successors to Renault Freres Agency, trying to make the public believe that they are successors to ourselves. The positive facts are as follows:

Bernin and Tilston had a contract with Renault Freres, which expired September 30, 1906, and which was not renewed. Renault Freres, of Billancourt, France, decided to open their own branch house in New York, which is known as the Renault Freres Selling Branch. Owing to the fact that the firm of Tilston & Bernin could not make any contract with Renault Freres for 1907, Mr. Bernin severed his connection with Mr. Tilston, and is now with me as superintendent. Mr. Tilston has no right whatever to use the name of Renault Freres Agency, or call himself successor to Renault Freres Agency, as he is not. C. A. Tilston & Co. are successors to Bernin & Tilston and nothing more. Mr. Tilston has some cars left on his 1906 order, which, of course, he can sell, but he has no cars for 1907.

I would further state that all the cars delivered to Renault Freres Selling Branch bear our special plate, protecting them against any claim arising from the Selden patent. We are not licensees, and we defend all our customers against any prosecution from the Selden association. All purchasers of Renault cars should request their cars delivered with our special license plate in order to be sure of being protected in the event of any trouble arising from Selden patent.

I hope this letter will impress upon the public what the real facts are, and destroy any misunderstanding which may have occurred through misleading advertisements.

PAUL LACROIX, General Manager,
Renault Freres Selling Branch.

New York City.

THE EFFICIENCY OF FRICTION DRIVE.

Editor THE AUTOMOBILE:

[607.]—One of the most interesting questions at present before automobile engineers is the one relative to friction transmission. The accepted type of friction transmission seems to be that involving a flat-faced disk, which is traversed by a wheel rimmed with some frictional substance. So far as we have been able to find, this device does not occur in other field of power transmission, except in connection with very small powers, and the obvious reason for its rarity seems to be that it is a faulty element, both in theory and in practice.

It is obvious that all points in any radius drawn in the revolving disk are moving at different speeds. It is equally plain that the traversing wheel can only revolve at one speed at a time. It would seem, then, that this is the case: One line in the rim of the traversing wheel follows a line in the disk, all other

points in the line of contact slipping to a greater or less degree. Small wonder that under such conditions the friction rim requires replacing after comparatively few miles of car-travel.

All data regarding friction-transmission which is at present accessible naturally deals with the rationally-designed spur and bevel-frictions, but a glance at this data serves to make more glaring the faults of the traversing-disk transmission. Some time ago a series of exhaustive tests were conducted at Purdue University to obtain facts relating to friction transmission. From the results of these tests we find that a friction-wheel (spur) 24-inch diameter by 2-inch face at a speed of 1,000 revolutions per minute will transmit 11.42 horsepower, when the pressure between the surface is 150 pounds per square inch, which pressure was found to be most efficient. Now, a representative designer of the traversing-wheel device transmits, or says he transmits, 24 horsepower through a wheel 20 inches diameter by 2 inches face at practically all speeds of his motor. As pointed out before, this device has only a single point of perfect contact, while the device from which the foregoing data was obtained brought into play a 2-inch line of contact. Wherein lies the discrepancy? The only possible means of increasing the capacity of the transmission would be to increase the pressure between the friction-surfaces. This, needless to say, wastes enormous power through friction and throws unnecessary strain upon all parts of the mechanism. In view of these facts, some brake-tests taken from the transverse shaft would prove interesting.

It might be well to say that the foregoing has been written entirely from the standpoint of a student of mechanical engineering and is in no way dictated by partiality to any particular car.

W. Lafayette, Ind.

LOUIS RUTHENBURG.

MORE LIGHT ON CURRENT CONSUMPTION.

Editor THE AUTOMOBILE:

[608.]—I have been much interested in the discussion that has been running through your columns, concerning the amount of current consumed by the ignition systems of different engines, varying in accordance with the number of cylinders. One important point, though, I think has been missed by all of your correspondents, this having to do with the "surge" of current following immediately upon each contact. Each of these surges takes much more from the battery than does a single contact for a longer period, and therefore is a factor that cannot safely be left unconsidered. In fact, with many cylinders, and ordinary high-tension ignition with battery, I believe it can be shown that the current consumption is less when the vibrator is kept buzzing continuously and the current commutated only in the secondary. The Dock five-cylinder motor shown at the National Motorboat Show, at Madison Square Garden, New York City, during last week, had such an ignition system, and the makers claimed a very much lower current consumption than when a contact breaker was used in the primary.

Mt. Vernon, N. Y.

ERNEST KOBBE.

THE ORIGIN OF THE WORD LIMOUSINE.

Editor THE AUTOMOBILE:

[609.]—With further reference to the query of Funk & Wagnalls as to the origin of the word limousine, it may be interesting to state further that the type of half-closed-in carriage body which now, in automobilia, bears the name, is a species very common in Bas-Limousin, now the Département du Corrèze of modern France. The Paris carriage builder who gave this name to his carrosseries may have been from the Limousin; probably was, but the limousine is a type of carriage body for a sort of diminutive stage coach—already in use for long years, perhaps centuries, in that particular part of mid-France which was formerly the Limousin. The French peasants' sabot, if it is an ample, full-bodied one and not a mere shuffleboard, is also a limousine, being of the same origin.

FRANCIS MILTOUN.

Jonquiers—Martigues B. du R., France.

NO AUTO FATALITIES IN VERMONT.

Editor THE AUTOMOBILE:

[610.]—On page 324 of "The Automobile" of February 14 is a paragraph on Vermont's low ratio of automobile accidents. The paragraph shows how fast an arrow will travel. The St. Albans "Messenger" spoke inadvertently of one death from automobiles, but did not say that the death was that of a Vermont woman while visiting in Springfield, Mass.

The truth is that there was not one killed in Vermont during 1906 by automobiles, directly or indirectly. I called the attention of the St. Albans "Messenger" to its editorial in which, I told them, the inference would be that somebody had been killed in Vermont by automobiles; they corrected the statement in a subsequent edition.

Barre, Vt.

JOHN W. GORDON.

COPPOCK ONE-TON COMMERCIAL CAR

IN view of the totally unskilled class of drivers into whose hands commercial trucks are usually placed, it would appear that the two-cycle type of motor should be particularly suited for this class of work, for obvious reasons. More than this, such vehicles are expected to run eight to ten hours a day and seven days a week with a comparatively small amount of time in which to overhaul them, so that it will be evident that nothing can be too simple to insure regularity of running coupled with endurance. The latest entrant into this field is the Copcock Motor Car Company of Marion, Ind., and in designing trucks for this purpose every effort has been bent toward preserving that utter simplicity of design and fewness of parts which tends toward the realization of a foolproof piece of mechanism—something that is of paramount importance, considering the purpose in view. For the present this firm is specializing on one and three-ton trucks, bodies being built to order.

Motor.—The power plant of the one-ton truck known as Model A consists of a two-cylinder, two-cycle motor of the three-port type, the cylinder dimensions being 4 1-2-inch bore by 5-inch stroke. They are cast without water jackets and the exterior of the cylinders round the jacket space is machined in order to insure a perfectly round cylinder at all points and to equalize expansion. A spun copper jacket weighing but 16 ounces complete is em-

ployed and is held in place by hexagonal bronze nuts top and bottom, permitting its ready removal and providing insurance against leaks at these points. The weight of the finished cylinder, minus its jacket, is 16 1-2 pounds, so that complete it only weighs 17 3-4 pounds. Its appearance without the jacket is clearly revealed by the illustration, showing cylinders ready for assembling

The cylinders are finished by a special reamer, the pistons and rings being ground to size. The last named are the Cartwright type of steam packing rings, the outer ring being 5-8 inch wide by 1-8 inch thick and split at 45 degrees. This is the master ring and under it are two eccentric rings measuring 3-16 by 1-8 inch. All the rings are held by a single pin passing through the lap of the master ring and between the two eccentric rings, an allowance of 1-16 inch in depth of the ring groove over the height of the two rings being made to facilitate lubrication. Exhaustive tests have shown this method of arranging the rings to be proof against carbon deposits working under them, which is said to be a more or less common fault with the two-cycle engine. The crankcase is of a special aluminum alloy, the lower half being made in two pieces flanged together at the center to permit of adjustments being made on either rod without the shaft dropping out during the operation. The crankshaft bearings are babbitt and bronze, the outer bronze shell having 24 studs cast on it, extending through the babbitt lining. The babbitt metal is forced into these shells under heavy hydraulic pressure and afterward machined to size in order to produce the best possible wearing surface. Three 4-inch bearings support the shaft. The latter is a hand forging of 30-point carbon steel and is finished all over, the journals being ground to size. The big end bearings of the connecting rods are split in the usual manner but are overlapped as in steam practice. Each half is held by a 3-16-inch dowel to prevent the hox from rotating. These holes are drilled with special jigs so as to insure perfect fitting of renewals, which is an important consideration.

Motor Accessories.—The carbureter is of the standard float-feed, automatic compensating type. One set of hardened nickel-steel spiral gears working at a 45° angle, serves to drive both the water-circulating pump and the timer, the timer shaft being mounted on three ball bearings, due provision having been made for adjustment in case of wear. The driving gears are encased in a bronze housing at the front of the motor and work in grease. The pump is of the standard gear type, having 3-4 inch inlet and outlet. The remainder of the cooling system comprises a vertical

TWO-CYCLE POWER PLANT COMPLETE.

fin tubular radiator placed forward under the footboard and having 176 lineal feet of tubing. It is supplemented by a four-bladed fan belt driven directly from the crankshaft, provision being made for maintaining the belt tension by means of an adjustable vertical support. The fan itself is mounted on ball bearings carrying sufficient oil for a year's service without replenishing supplies.

FINISHED PISTON AND RINGS.

Lubrication. — A gear-driven, force-fed oiler provides a positive means of lubricating the piston and connecting rods. One oil lead terminates at a boss on the outside of the cylinder communicating with a groove 3-16 inch wide by 1-8 inch deep inside the cylinder. This groove extends around from one side

of the piston pin to the other, thus entirely surrounding the piston with the exception of the space occupied by the pin, which is 1-8 inches in diameter. This groove is never uncovered by the travel of the piston, the latter coming within 1-8 inch of it at top and bottom. For the lubrication of the big end bearings the piston pin is hollow two-thirds of its length. A second oil lead registers with this hollow end. The wrist pin is drilled so that when the crank is in a vertical position oil is fed to the end of the rod, and when in a horizontal position the hole in the pin registers with a tube running down the channel of the rod to the big end. This system has been designed to run with a minimum amount of oil and no waste, and to test its efficiency the crankcase of a car that had been in service steadily for two months was removed and found to contain hardly an ounce of oil in the bottom of either of the compartments.

Grease is used to lubricate the crank journals and is fed from cups placed on the dash, the leads consisting of 3-8-inch 18-gauge copper tubing. Placing these cups away from the heat of the engine prevents the grease from melting and also keeps them under the eye of the driver at all times.

Transmission.—The clutch is of the internal expanding type, consisting of a bronze shoe 10 inches in diameter and having a

2 1-4-inch face, 8 per cent. of which consists of cork inserts. The two parts of the shoe are hinged and expanded by means of a flat cam; they are supported by a cast steel web, the drive being taken from this point to the square shaft of the transmission. The latter is of the progressive type providing three speeds forward and reverse, the pinions all being of hardened nickel steel with a 1-inch face of 6 pitch. The bevel pinions are also of the same material but of 4 pitch. All shafts run on Timken roller bearings of large size. The cross countershaft is squared where it passes through the differential case to permit of easy removal. The outer ends of this shaft run on American roller bearings. Final drive is by means of generously proportioned double side chains.

Running Gear. — The frame is of cold-pressed nickel steel, supported on semi-elliptic springs front and rear, the former measuring 2 by 40 inches and the rear 2 1-4 by 48, both having eight leaves. These are supplemented by a cross spring at the rear measuring 38 inches in length and also having eight leaves. The front axle is a 1 3-4-inch drop forging of I-beam section, while the rear is a 1 3-4 piece of square section. The wheels are 32 inches in diameter and run on Timken roller bearings. They are shod with 3 1-2-inch solid Diamond tires front and 4-inch rear. Brakes are carried on the cross countershaft, one being placed on either side of the differential, in addition to which there is a set placed in drums on the driving wheels, the latter being of the contracting type, cast steel shoes bearing on a steel drum 10 inches in diameter by 2 1-2-inch face. As is customary in touring car practice, the former set or countershaft brakes are operated by a pedal and used for running while the hub brakes are operated by a side lever and constitute the emergency.

AUTO CLUB NEWS FROM ALL SECTIONS

Windy City Autoists Prepare for a Season of Activity.

CHICAGO, Feb. 24.—The directors of the Chicago Motor Club have accepted the resignation of President William H. Arthur and named F. C. Donald to succeed him, choosing David Beecroft to fill Mr. Donald's place on the directory. It has been decided to arrange for a reliability contest, a hill climb, an economy test and a braking and skidding contest. The first three events were held last summer by the Chicago Automobile Trade Association, but the Chicago Motor Club believes that the dealers will be pleased to turn over these affairs. The braking and skidding tests are a new venture and it is believed will provide a novel and interesting competition. To handle these events a committee has been formed consisting of Charles P. Root, chairman; Joseph F. Gunther and Walter L. Githens.

Rules for the economy test have already been outlined, though the event will probably not take place until next August. There will be an eliminating competition over a 100-mile course and three cars will qualify for the finals against the Silent Knight machine, instead of one as first proposed. This means that four high-powered machines will be in competition for the trophy which the Chicago Motor Club will purchase with the \$500 check put up by Charles Y. Knight when he challenged any car in the country to an economy test. The test will be over a 100-mile course and the final over a 300-mile route, the last part taking three days to decide. Touring machines only are eligible; they must weigh about ten and a half pounds to the cubic inch of piston displacement and must carry a stipulated load of dead weight. No limit will be placed on the size of the machines, competitors are free to make any carbureter adjustments they desire, curtains may be placed over the radiator and fans disconnected, but no additional water supply can be obtained. A standard body and tires must be used as well as a standard gasoline tank; the placing of a tank on the dash will not be allowed.

Considerable activity is being shown in the Chicago district on the signboard movement. Joseph F. Gunther, chairman of the runs and tours committee of the Chicago Automobile Club, is trying to secure the co-operation of the Chicago Motor Club and the Chicago Automobile Trade Association with his own club to give to the district a complete series of signboards.

Chicago automobilists are only partially satisfied at the recommendation of the American Automobile Association to start the Glidden tour from their city. Formal action in the matter was taken when the Chicago Motor Club appointed a committee to work for the terminating of the tour at Chicago. The committee favors a start in New York City and a westerly run by what is known as the national route leading through Syracuse, Rochester, Buffalo, Cleveland, Toledo, and South Bend. It is expected that the two other auto associations, the Automobile Club and the Automobile Trade Association, will form similar committees and that the three will work together for the common end.

Edw. Kneeland Elected President Pittsburg Club.

PITTSBURG, PA., Feb. 25.—At the annual election of the Automobile Club of Pittsburg, held February 18, the following board of officers were elected for the ensuing year: President, Edward Kneeland; first vice-president, George E. Painter; second vice-president, W. N. Murray; third vice-president, Frederick Byers; secretary, Paul C. Wolff; treasurer, George G. Glass; board of governors, one year, William P. Baum; two years, Jno. C. Bragdon; three years, Philip S. Flinn, Dr. John A. Hawkins, C. M. Miller. The attendance and interest shown were greater than at any time in the club's history. The treasurer's report showed the organization to be in excellent condition financially, and the report of the secretary showed an increased membership list.

Jersey Autoists Eat Their Annual Dinner at Newark.

NEWARK, N. J., Feb. 25.—The third annual dinner of the New Jersey Automobile and Motor Club, which has now a membership of 800, took place at Achtel Setter's Wednesday evening of last week. Autoists from all sections of the State were present, and among the guests were State Commissioner of Motor Vehicles J. B. R. Smith, of Trenton, and Winthrop E. Scarritt, of East Orange, ex-president of the A. A. A. A number of plans were discussed informally, covering all fields of automobiling, sporting, legislative, touring and the holding of various tests of public utility. Mr. Scarritt, who was the principal speaker, said that New Jersey had more miles of macadam road than any other State and of the 4,000 miles in the United States this State boasts of 1,100 miles. Soon the greatest friend of the automobile would be the New Jersey farmer, because the good roads that are being constructed will increase the price of every farm. Considerable interest was displayed in the plans for the five or six-day endurance run that the club has decided to hold early in the spring, probably late in April or early in May. It is proposed to map out a 500 or 600-mile tour, probably into Pennsylvania, with rules framed somewhat on the lines of the Glidden Cup tour regulations. They will be stringent enough to provide that the cars must not only cover the prescribed distance without making repairs, but also within a stated time. H. A. Bonnell, secretary of the club and chairman of the contests committee, expects to announce the route and conditions very shortly.

R. I. Automobile Club Names Its Standing Committees.

PROVIDENCE, Feb. 25.—Standing committees for the current year were appointed at the recent meeting of the board of directors of the Rhode Island Automobile Club. With the election of the new house committee, the entertainment committee passed out of existence, the functions of both committees being combined in the house committee, of which Dr. Church retains the chairmanship. On the runs, tours and contests committee Eugene M. Sawin takes the place of R. Lincoln Lippitt.

In addition to selecting the make-up of the committees, the directors named its representatives on two of the boards of the American Automobile Association. Four new names were also added to the membership rolls. The personnel of the chairmen of the committees is as follows: Membership, Charles O. Read; house, Dr. Wm. P. Church; runs, tours and contests, Elliot Flint; laws and ordinances, Dr. Julian A. Chace; auditing, B. J. Horton.

Elliot Flint was chosen to represent the club on the touring committee of the A. A. A. and J. Jerome Hahn was reappointed as the Rhode Island representative on the law committee of the National Association.

Complete Harmony in Missouri on Legislative Matters.

ST. LOUIS, Feb. 23.—Roy F. Britton, secretary of the Automobile Club of St. Louis, has taken exception to the statements published in THE AUTOMOBILE of February 14 relative to automobile legislation in the Missouri General Assembly. Complete harmony, declares Mr. Britton, prevails between the St. Louis and Kansas City clubs. The two bodies have always worked in unison, and up to the present time there has been no disagreement between them and only the best of feeling prevails. No automobile was used at Jefferson City to make demonstrations to members of the Legislature. The Botsford bill referred to is a bill introduced by Mr. Botsford at the request of the Automobile Club of St. Louis. The St. Louis and the Kansas City clubs had each a representative at Jefferson City to further the interests of the bill, but they are working in perfect accord.

In connection with the St. Louis automobile show, to be held in the Jai Alai Building from April 1 to 6, an automobile floral

parade will be held on the morning of Monday, April 1. It is expected that at least 150 machines will take part in the parade, which will go over the downtown streets. Ten silver cups will be awarded to the best decorated machines. Dave Strauss, promoter of the show, states that while in Chicago he made arrangements to have the moving pictures of the Vanderbilt Cup exhibited at the St. Louis automobile show.

The members of the St. Louis Automobile Club have approved of the plan to establish a chauffeurs' information bureau. Club members have pledged themselves to employ only drivers who possess certificates issued by the club secretary. Drivers will be required to file an application stating their occupations during the last five years, give references to their character and their ability to operate machines. If the secretary is satisfied with the information the applicant will receive a certificate, which will entitle him to consideration for employment by club members. By this plan it is hoped to materially reduce the number of irresponsible drivers.

Ohio Valley Autoists Elect Officers.

WHEELING, W. VA., Feb. 23.—At a recent largely-attended meeting of the Ohio Valley Automobile Club, held in this city, a constitution and by-laws, prepared by Attorney F. A. Chapman, of Wellsburg, were adopted and the annual election of officers was held, resulting as follows: President, M. F. Giesey, of Wheeling; vice-president, F. A. Chapman, of Wellsburg; S. Ott Laughlin and A. W. Paull, of Wheeling, and S. W. Meals, of Moundsville; secretary, T. A. Westmeyer, of Wheeling; treasurer, A. A. Wheat, of Wheeling. A board of directors consisting of six members was also elected.

It has been decided by the club to place danger signs along the roads wherever they are needed. An amendment to the bill now before the legislature limiting the speed of automobiles to four miles an hour is now being prepared and will propose a six miles limit. Several other changes are also asked for, some reducing the existing penalties and others asking for an increase, it being the opinion of the club that the present penalties err in some cases by leniency and in others are unnecessarily severe. The club has a membership of forty owners of automobiles.

Denver Autoists to Build a \$10,000 Clubhouse.

DENVER, COL., Feb. 22.—Ten thousand dollars will be invested in the new clubhouse of the Colorado Automobile Club, the preliminary plans for the erection of same having been submitted to and approved by the members at the recent annual meeting of the club. Probably there was never a more successful club, considering the length of time since its founding and the difficulties to be contended with, than the combination of good citizens which bears the name of this grand State and automobile club as the other two-thirds. A good roads movement has been so ably pushed that indications are that within a short space of time tourists from all over the world will flock to Colorado with their cars to enjoy this unsurpassed climate, scenery and the coming unsurpassed highways.

The annual election resulted as follows: President, Dr. F. L. Bartlett; vice-president, J. W. O'Connor; secretary, Dr. W. H. Bergtold; treasurer, Louis Searing; two additional members of the executive committee, F. O. Stanley, J. H. Carson. James H. Pershing, a prominent member of the Denver bar, delivered an entertaining lecture on "The Law of the Road."

Wisconsin to Form a State A. A. A. Association.

MILWAUKEE, Feb. 25.—Wisconsin automobilists can now become affiliated with the American Automobile Association through a State organization. At the recent meeting of the Milwaukee Automobile Club it was decided to organize a State division of the A. A. A. in Wisconsin, and Secretary Drought will apply for admission into the national body at once.

James Drought was recently elected a director of the A. A. A., and it was chiefly through his missionary work that Wisconsin was brought into the fold.

THE AUTOMOBILE CALENDAR.

AMERICAN.

Shows.

- March 2-9.....—Minneapolis, Automobile Show, First Regiment Armory, Minneapolis Automobile Dealers' Ass'n.
 March 2-9.....—Chicago, Second Annual Power Boat Show, Seventh Regiment Armory. W. C. Andrews, manager, 19 E. Huron St.
 March 4-10.....—Kansas City, Mo., First Annual Automobile Show, Convention Hall. Frank L. Woodward, manager, Willis Wood Theater Building.
 March 9-16.....—Boston Automobile and Power Boat Show, Mechanics' Hall and Horticultural Hall, Boston Automobile Dealers' Association. C. I. Campbell, mgr.
 March 13-16....—Omaha, Auditorium, Second Annual Automobile Show, Omaha Dealers' Association. T. Gillman, manager.
 March 18-23....—Providence (R. I.) Automobile and Power Boat Show, Infantry Hall. F. M. Prescott, manager.
 April 1-6.....—St. Louis, Mo., Automobile Show, Jal Alai Building, St. Louis Automobile Dealers' Association.
 April 6-13.....—Montreal, Canada, Second International Automobile and sportsman's Exhibition. R. M. Jaffray, manager, 309 W. Notre Dame Street.
 April 8-13.....—Pittsburg, Pa., First Annual Show of the Pittsburg Automobile Dealers' Association, Duquesne Garden.

Races, Hill-Climbs, etc.

- April 8-9.....—Harrisburg, Pa., Two-day Endurance Run, Automobile Club of Harrisburg.
 May 30.....—Philadelphia, Hill Climb, Quaker City Motor Club.
 Oct. 19.....—St. Louis, Mo., International Aerial Race for the Gordon Bennett Prize. Aero Club of America.

Motor Boat Races.

- June 8.....—670-Mile Ocean Motor Boat Race, New York to Bermuda. Motor Boat Club of America and Royal Bermuda Yacht Club.

**European Autoists Have In less than two months Europe
a Mixed Program.** will have opened its annual competitive campaign, and the small army of professional drivers will once more be plunged into the strenuous life. The slack period is only of short duration, for the return home from the autumnal Vanderbilt contest is followed by a few minor competitions, and it is not until the end of the year that the racing and demonstration machine is allowed to take its ease. April 21 Italy will set the ball a-rolling with its Targa Florio, driven by officialism to the island of Sicily. Germany enters the arena shortly after with its Herkomer Cup contest for amateur drivers, and its Kaiser Cup race with ninety-two professional drivers. July will be ushered in by the French Grand Prix in Normandy, with the Sporting Commission Cup as a feeble prelude. Attempts will be made to lower world's records at Ostend during the middle of the month, and towards its end Belgium will organize its Ardennes Circuit for racers and Liedekerke Cup for fast tourists. The first week in August will see the familiar crowd of auto enthusiasts in the neighborhood of Trouville for the tourist competition and race that the Marquis de Dion has at last persuaded his club to undertake. Britishers will betack themselves to the Isle of Man towards the close of the summer to glory in the tourist race which the cast iron laws of the Empire forbid on the mainland. Brescia, in Northern Italy, will be the scene of a big September race. Minor contests will fill in the gaps between these big events and carry the season along until the muggy weather of November puts a cloud over all.

The outstanding feature of the European program is its diversity. There is intense activity but no unanimity as to the most profitable type of contest. France has abolished the old weight limit and imposed a fuel allowance of such latitude that there is no fear of a diminution in the speed of her flyers. Italy and Germany have something in common in that both have imposed a limited cylinder area; Belgium remains true to old conditions, and Great Britain has its fuel allowance hedged around with numerous restrictions.

This condition of affairs is not altogether advantageous. Each nation is proud of its own formula and jealous of the success of rival events. The manufacturer has his difficulties, for under the new conditions he is unable to participate in as many events as formerly, owing to the diversity of regulations and the impossibility of building a special machine for each race. That the year will be a profitable one cannot be doubted, but it will prove the necessity of more uniformity of action.

The Two-Cycle Motor for Commercial Use.

There appears to be every reason to believe that the two-cycle motor will find its first great development in the field of the gasoline-driven commercial vehicle rather than in the pleasure type. For unvarying reliability, coupled with great endurance, no mechanism that is to be trusted to the tender mercies of an unskilled driver can be made too simple. What appears to the mechanically versed to be the very acme of simplicity, not infrequently puzzles the uninitiated unduly, its very lack of apparent complication lending it an air of mystery. Be this as it may it is obvious that the two-cycle type of motor, with its lack of small moving parts, offers a very high factor of safety against breakdown in the hands of drivers whose knowledge is so limited that they are apt to overlook such a thing as the need of lubrication.

The power plants of such vehicles must, not alone, be as nearly fool proof as it is possible to contrive them, but they must also be as nearly automatic as it is possible to make such a piece of machinery. The two-cycle motor lends itself to these requirements admirably. In the three-port type, which appears to represent the most advanced form in use to-day, there should be no need whatever for the driver to pay attention to anything other than the regularity of the lubrication and the needs of driving during the course of a day's work of ten or twelve hours. Moreover, the absence of small parts removes the temptation to fuss and fiddle in the attempt to find, what is more frequently than not, a wholly imaginary wrong. By giving such trucks a reasonable amount of attention night and morning, by one versed in their mechanism, it should be possible to keep them running through an entire season's work without serious repairs. In other words, without any necessity for being in the shop any oftener than the ordinary dray or its four-footed power is.

All-the-Year Autoing Now Holds General Sway.

Nothing has accentuated the fact that there is no longer a closely defined automobile season so strongly as the easily demonstrated superiority of this form of transportation during the extended periods of inclement weather that have marked the present winter. The transition from the time when it was considered a worse than profitless undertaking, by all but the few who gloried in a strenuous pastime, to keep a car out of storage once the ground was covered with snow, to the present, when it is an exceptional case in which a car is put away at all, has been very rapid. The closed body has brought comfort with it, but only the vastly improved reliability of the machine as a whole has made its continued use under such conditions a possibility.

There is still a closed and open season, however, though the line of demarcation is no longer well-defined. While the majority of autoists now keep their cars in commission the year round, it is principally for city use or short trips when the weather favors. Touring is still a summer pastime, and balmy weather marks the coming of the open season.

AMERICAN DRIVERS FOR AMERICAN CARS.

Albert L. Pope, first vice-president of the Pope Manufacturing Company, commenting on the next Vanderbilt Cup race, expresses the following views:

"The subject of another Vanderbilt Cup race is of widespread interest, not only throughout the United States, but across the Atlantic. A good many inquiries are being made concerning the details of this event, and I have on many occasions expressed myself to the effect that we expect to enter several cars for that race. We feel that it is not an essential feature to fix a maximum limit of horsepower in the contesting machine, although we do believe in the present French system of fixing an outside limit of weight.

"The season of the year has been more or less discussed, but we are inclined to the opinion that October furnishes the best environment and weather conditions to run this contest, and we know of no better place in America than the new automobile highway on Long Island, provided that is completed in season. Otherwise, any course similar to the one already used on Long Island, which would cover a distance of approximately 300 miles, seems most advisable. Long Island is particularly well located, and its topography well suited to the general conditions required in a fair automobile contest of this kind.

"We are strong believers in the policy of having American machines driven by American-born citizens, and we would like to see the next Vanderbilt Cup race run under approximately these conditions, with the addition of such other details in arrangements as are found necessary to the proper regulation and safe-guarding of the contest."

THOMPSON SAYS PARKWAY WILL BE READY.

"Enough of the Long Island Motor Parkway sufficient for the holding of the Vanderbilt Cup race will be completed beyond any possible doubt," said Chairman Jefferson DeMont Thompson, of the A. A. A. Racing Board, when asked the other day, probably for the thousandth or more time. Duncan Curry, of the *New York American*, was the questioner, and according to what Chairman Thompson told him, the race may take place in the vicinity of Riverhead, which will be at the east end of the parkway. Since the international balloon race of the Aero Club of America will take place at St. Louis, October 19, it appears probable that October 12 will be the date of the Vanderbilt race, the American Elimination trial being held a fortnight previous. Mr. Thompson is treasurer of the parkway, in addition to being chairman of both the Racing Board and the Vanderbilt Cup Commission. Therefore, he should know what he is talking about.

MARRIOTT ACTS AS A STARTER AT ORMOND.

ORMOND, FLA., Feb. 22.—At some impromptu automobile races held to-day at the Ormond end of the beach, Fred Marriott, who nearly lost his life at the recent meet, acted as starter, and has apparently thoroughly recovered from his frightful experience met with in the wrecking of the Stanley "Teakettle." To-day's winners included C. W. Seamans, of Brooklyn, two-mile event; W. A. Adriance, of Poughkeepsie, potato race, and R. H. Kimble, of Omaha, obstacle and novelty races; J. H. McCarthy, of Boston, figured as the winning owner in the motor boat race, in which there were seventeen participants.

FRANCE AFRAID OF THE INVADER?

A cablegram from Paris to the *Sun* announces that *Les Sports*, one of the leading French daily automobile journals, violently attacks the proposed tour of American automobiles through France as dangerous to the French industry, and demands that it be prohibited. *La Presse*, a leading evening journal, concurs in this demand. Both papers maintain that if American manufacturers want to advertise the capabilities of their cars they should enter the French tests or allow French cars to participate in the tour.

CHRISTIE'S GRAND PRIX ANNOUNCEMENT.

Walter Christie, the solitary American entrant for the Grand Prix, last week gave an informal dinner at Martin's, New York City, which function was utilized by Mr. Christie in informing the metropolitan press representatives of his intention to compete in the big French race. Besides the press men, the guest list included Alfred Reeves, Sumner Healey, ex-Senator Barcus of Indiana, S. M. Butler, J. B. Lozier, Samuel Bogart, A. Carter, Georges Dupuy, and Harry Treadwell. Louis Strang, who will serve as mechanic, as in the past, on the Christie craft, was also present. The newspaper men told Mr. Christie that he had supplied them with more or less sensational news in the past, and they hoped that the foreign chapter which he was to contribute would be equally interesting. The indefatigable American intends to locate on the French course several weeks before the race and become thoroughly familiar with every kilometer. The Christie racer is very nearly completed, and will be ready for trying out in less than a month.

NEW JERSEY'S REVENUE FOR ONE YEAR.

TRENTON, N. J., Feb. 25.—Commissioner J. B. R. Smith, of the Department of Motor Vehicles, estimates that the automobile receipts for the fiscal year ending May 1 will be about \$80,000, which money will be expended in repairing the improved roads of the State, providing the legislature legalizes this expenditure.

Up to January 1 the department registered 13,759 vehicles and issued 15,269 licenses to drivers. At that date the amount of fees collected was \$62,233.91. The receipts of the department in January for registration and licensing amounted to \$1,193.17, and at the close of business last Saturday the receipts from these sources were \$506, making the total receipts from May 1, \$63,933.08.

Up to January 1 there had been collected \$991 in fines. In January the fines collected amounted to \$111 and in February \$470, making the total receipts from this source \$1,572.50. The aggregate receipts of the department to date are \$65,505.58.

"DIPLOMAED" CHAUFFEURS INELIGIBLE.

As in every other walk of life, the man who has gained his knowledge of automobiles entirely in the hard school of experience looks down contemptuously upon the would-be chauffeur and his "book-learning." To judge from the statements of some of the speakers at the preliminary meeting of graduates of the New York West Side Y. M. C. A. to form a club, the contempt takes the form of positive enmity. "College graduates" need not apply, seems to be the feeling, and the advice to say nothing about being such was freely handed round. After much discussion, it was finally decided to call the new organization the Motor Club of the West Side Y. M. C. A., though the last part of the name occasioned much trouble, and it was seriously proposed to omit it owing to the prejudice referred to. The lengthy appellation was finally adopted, however.

MORA CAR MAKES INTER-CITY RECORD.

One of the cars exhibited by the Mora Motor Car Company, of Rochester, was run to the Buffalo show under its own power in the record time of 2 h. 30 min. Mr. Mora made this statement in the course of a conversation, and A. Vernon Hart, a Rochester dealer who has had experience over the roads in question, immediately laid a wager that it could not be done in such a time under prevailing conditions. The wager was accepted. Driven by W. M. Birdsall, its designer, the car left Buffalo at 8 A.M. Sunday, reaching Batavia at 9:07, where Ray Hollis took the wheel. The entire drive was in the face of a blizzard, but the car arrived at Rochester at 10:13:45, having done the distance in 2 h. 13 min. 15 sec., or with 16 minutes and 15 seconds to spare. Robert Thompson and William Likly acted as referees and timed the arrival of the car at the Rochester end.

EMPEROR'S CUP HAS 92 ENTRIES.

BERLIN, Feb. 15.—Five European countries will this year organize five important speed contests, all on different lines. England has its Tourist Trophy, a speed test for touring machines with a limited fuel supply and a weight limit; France has its Grand Prix, a racing event pure and simple, with a limited but generous fuel supply; Italy holds to its Targa Florio, with a limited cylinder area; Belgium has its fast Ardennes circuit, in which racers must submit to the old weight limit, and Germany has its Emperor's Cup, nominally for touring machines, but in reality for racers with a limited cylinder volume.

OFFICIAL COURSE FOR EMPEROR'S CUP.

The main regulations of the German event, which will be held June 14, are cylinder volume limited to 10.56 pints; minimum wheelbase, 118 inches; minimum height of seats, 93.4 inches; minimum weight, 2,585 pounds; road clearance, 6 inches. Ninety-two entries have been received for the race, the number being the largest on record for any speed contest. The nations represented are: Germany and Austria, 33; France, 23; Italy, 20; Belgium, 10; England, 4; Swiss, 2. Owing to the large number of contestants, some difficulty has been experienced in finding a suitable circuit, and for a time it was thought that the number of cars per firm would have to be reduced from three to two. This has been avoided by lengthening the course to seventy-five miles without any controls or neutralizations. Even with this length of course the leading cars will be round to the starting point before the last starters have begun their run, but special precautions will be taken to prevent accidents from this cause.

As will be seen from the accompanying map, just issued by the Automobile Club of Germany, the course is a modification of the Taunus circuit, on which the 1904 Gordon Bennett race was run. On that occasion the course was taken left-handed; this year the German race will be run right-handed. The headquarters of the circuit will probably be Kloster-Thron, a few miles to the north of Saalburg, where the Gordon Bennett headquarters were fixed. From this point the arrival of the racers can be seen for a considerable distance; they will descend the hill towards Werheim and climb up the short hill leading to the grandstands.

It is expected that the Emperor will be present in person at the race, and every effort will be made to make the grandstand worthy of their royal occupant. The Imperial pavilion will occupy a central position with a grandstand on each side, the whole placed obliquely so as to obtain a good view of the machines from the time they begin to descend the hill towards the grandstands. Seventy thousand dollars have been received in entrance fees, and the club officials declare that they will not spare the funds to obtain a perfect course and elegant stands. The weighing-in ground will probably be at the west side of the course, a considerable distance from the start. A special loop has been built on the course to allow of turning after the race.

GRAND PRIX DATE IS JULY 2.

PARIS, Feb. 18.—Although no official announcement has yet been made, we are able to state that the Grand Prix of the Automobile Club of France will be held on the Dieppe course on Tuesday, July 2. In fixing a date account has to be taken of the local markets, for although the Norman population is enthusiastic over the auto race, and would make no objection to the pulling down of a bridge or the stoppage of the entire railroad service, the disarrangement of the little country markets would not be tolerated. As Tuesday is the only day on which no market is held in the towns on the course, it will certainly be the day chosen for the race. A formal assurance has been given by the prefect, the local deputy, and other officials that a subvention of \$20,000 will be handed over to the Automobile Club of France and that certain road improvements will be carried out and the telegraph service reorganized at Government cost.

It has been practically decided to erect the grandstands at Pollet, four miles from Dieppe, facing the sea, and on the side of the triangular course running parallel with the English Channel. This is conceded to be the most suitable spot and will be accepted if satisfactory terms can be made with the owners of the land on which it is desired to build the stands.

Entries for the Sporting Commission Cup, to be run on the same circuit as the Grand Prix, only number nine, as follows:

- | | |
|-------------------------------------|------------------------------|
| 1. Gillet-Forest (De la Touloubre). | 6. La Bulre (———). |
| 2. Darracq (Wagner). | 7. Porthos (Strickert). |
| 3. Darracq (Hanriot). | 8. H. I. S. A., Italy (———). |
| 4. La Bulre (———). | 9. H. I. S. A., Italy (———). |
| 5. La Bulre (———). | |

These machines will cover about three hundred miles on exactly half the fuel allowance given to the Grand Prix racers. The contest was put forth as a rival to the German Emperor's Cup race, which has now obtained 92 entries, and was expected to unite a big number of machines of approximately the same horsepower as those for the German event, though running under entirely different conditions. With such a diminutive entry list the club officials have decided that it is impossible to run the race as a separate event, and the Sporting Commission Cup will consequently be run the same time as the Grand Prix. Here difficulties arise, for Wagner and Hanriot of the Darracq team and Strickert of the Porthos firm have been entered as drivers in both events. Should either of these firms object to the late change in the conditions of the race, there will be a deadlock. The failure of the Sporting Commission Cup could not be more complete, for, excepting Darracq, none of the five firms have had experience in long-distance speed contests.

WELCOMES THE GOLD CUP TOUR.

Commenting on the visit to Europe of American automobilists engaged in the American Gold Cup tour, Charles Faroux, one of the best known of French automobile writers, says that the project is one of special interest. "In the new world there are no roads; in the old countries, on the contrary, the national highways are one of the countries' glories. The organizers of the tour have wished to prove to the Yankees that a tour in Europe is not especially reserved to a few millionaires, but that a family of five can travel through these wonderful countries in automobiles cheaper than by rail, and in the hands of the agent who would treat them as so many bundles. This is not an American invasion, as some appear to think, for transatlantic manufacturers know full well that the hour of the Yankee commercial superiority will certainly not be in 1907. On the contrary, the desire of those engaged in the tour is to contemplate for once, and very widely, the marvelous panoramas of Eastern Europe. It is a project of the highest interest, which cannot fail to directly impress the prosperity of our tourist regions; that is why we will accord all our assistance to the American chauffeurs to assure them a welcome as worthy of them as of us."

NEWS BUDGET FROM BRITAIN.

LONDON, Feb. 20.—The chief recent event of competitive importance has been the preliminary test of the Side-Slip Prevention Competition. Out of the original total of forty-one devices entered, twenty-seven were rejected as impracticable at the examination of the drawings and withdrawals further reduced the number, with the result that only seven devices remained for the test at the Clement Talbot Works. The track had been carefully covered with a mixture of mud and soft soap, and on this compound the 'buses to which the devices were fitted had first to effect a sudden stop with brakes hard on, and in the second test a double right-left turn was attempted. The results were anything but encouraging, and the only effective device seemed to be Molesworth's six-wheeled vehicle, with back and front steering. However, the abnormal conditions created by the presence of the greasy compound must have materially affected the efficiency of the remaining six devices, and possibly better results will be attained in the long-distance trial in London streets, which completes the competition.

The 5,000 miles tire trials will be postponed till the spring of 1908. The best time of the year for these trials is February and March, and it has not been possible to make a start this month. Half of the trials will be run in England and the remainder in France.

Since the beginning of the year there has been the customary round of provincial exhibitions, few of which contain any improvements or alterations on the models introduced at Olympia. The show season will culminate in the Agricultural Hall Exhibition early in April, but before this event commences there is to be the big Commercial Vehicle Exhibition at Olympia, from March 7-16. The Society of Motor Manufacturers and Traders promotes this show, which is really an overflow of the November Olympia, and interesting evidence of progress in commercial vehicle and motor boat construction may be expected.

Probably the longest officially observed motor car trial yet entered upon commenced on Monday from the A. C. G. B. and I. clubhouse. A standard 30-horsepower Siddeley is now following a carefully mapped out tour of 10,000 miles through Great Britain in charge of the club's observer, who will note every delay and adjustment. A rather interesting record should result, particularly in the case of the tires, which are fitted with tubes of the new rubber substitute, Elastes. The claims advanced on behalf of this unpuncturable and resilient compound by many motor authorities will thus be afforded good opportunity of confirmation.

MINNESOTA AUTOISTS HAVE A BILL TO KILL.

MINNEAPOLIS, MINN., Feb. 25.—A protest against the Nelson "anti-automobile bill," as it is known, which has been introduced in the Minnesota Senate, was made by the Minneapolis Automobile Club at a meeting at which representatives of the St. Paul club were present. The automobilists characterized the bill as "too absurd for consideration." It is drastic in its provisions, reducing the speed limit materially, requiring examination of drivers and owners, and allowing county commissioners to close roads to automobile traffic whenever deemed necessary. A campaign for the passage of the bill has been started in the southern part of the State, and papers and legislators are being flooded with "anti-automobile" literature.

POST & LESTER CO. SETTLE AT THE HUB.

It has been rumored that the Post & Lester Company, the big supply dealers of Hartford, Conn., have been contemplating a descent on Boston for some time, and the report has now been verified. They are opening a branch at 815 Boylston street, which will be in charge of E. L. Thompson, formerly with the Angier Company. The new store will be in operation by March 15, and will carry a very complete line.

FINISHING POINT OF ATLANTA CLIMB—ROAD WAS EXCELLENT.
Photograph by Percy H. Whiting.

ATLANTA HAS A NOTABLE HILL-CLIMB.

ATLANTA, GA., Feb. 22.—The first hill climb ever held in Atlanta was run off to-day, and, barring the refusal to act of the timing apparatus, the affair went off smoothly.

The best time of the day was made by John Toole in Ed Inman's Stearns car. He covered the seven-eighths of a mile in 1:06 1-5, winning the free-for-all with a big margin.

Next to the Stearns and D. C. Lyle's Apperson, which took the hill in 1:19 2-5, Lowry Arnold's Buick runabout was the star of the collection. This car won the race for runabouts in 1:38 4-5 and the event for cars listing \$1,500 or under.

A Stoddard-Dayton, with James Todd at the wheel, won the race for cars costing \$3,500 and under in 1:25 1-5, and also, with the same car, the race for cars listing \$2,500 and under.

Handsome cups were given in every event. So successful was this hill climb, in which there were twenty-nine starters in the various events, that local enthusiasts are planning an endurance run from Atlanta to Macon—a distance of about 200 miles over all kinds of roads, mostly bad, and a Fourth of July race, perhaps forty miles in length, from Atlanta to Roswell, Ga., and return.

APPRAISER'S DECISION REVERSED.

On a recent invoice of cars sent to this country by the Societe Mors, Paris, one of the machines was invoiced as worth 21,000 francs, while another was entered at 6,300 francs. They were turned over to Appraiser Fowler, who reported that the cars were of a value in excess of the invoice prices. An appeal was taken from this ruling, and in a decision by I. F. Fischer, the Board of U. S. General Appraisers sustained the importers, reversing the appraiser in the first instance.

STARTING POINT OF THE ATLANTA HILL CLIMB, FEBRUARY 22.

REASSURING SITUATION AT ALBANY, N. Y.

ALBANY, N. Y., Feb. 25.—So far, legislation affecting autos has not progressed beyond the committee and introduction stage. But three bills have been let out of committees, and they are all of a character desired by automobilists or not objected to except one; and that is desired by some owners who frequently drive to New Jersey or Pennsylvania, is retaliatory in its nature and not calculated to accomplish the object it seeks. These three bills are:

Assemblyman Young's bill amending the insurance law so as to permit the formation of companies to guarantee against loss or damage to property resulting from accident to a duly licensed automobile; or loss or damage resulting from accident to a duly licensed automobile. This bill has already passed the Assembly and is in the Senate committee on insurance. This is the farthest advanced of any of the auto bills.

The next in order of advancement is the G. H. Whitney bill, which was reported while the delegation of the New York State Automobile Association were in Albany last week and was shown to them and they expressed no objection to it and have not interfered with its progress. It is now on third reading in the Assembly. It is an act to fix and prescribe rates of toll for autos on toll bridges and toll roads. The law now gives the corporations owning the toll-bridges and toll roads the right to collect toll from drivers of horse-drawn vehicles. This is the first legislative measure which has seen fit to place the motor vehicle on an equality with the animal-drawn vehicle, and the autoists hail it as an encouraging sign of progress, since they have been submitting to restrictions which do not apply to other vehicles which injure the roads more than the automobile ever can. For the most part toll roads and toll bridges have been collecting tolls without this special warrant of law and fixing their own rates. The legislative committee of the State association deemed it a good bill to allow to pass, as it will establish a precedent for equality of vehicles on the highways.

The other bill which escaped from committee did so by reason of an oversight on the part of those watching the legislation here in Albany. It is the Weber bill, and is the retaliation measure to make non-resident owners of automobiles coming into this State register and take out a New York license, just as New Jersey and Pennsylvania laws require of New York autoists. This is the same as the Apgar bill in the committee on internal affairs, which the legislative committee opposed at the hearing last week so successfully that it was not reported. The Weber bill was sent to the general laws committee, which reported it out and it is now on second reading in the Assembly. Had Chairman Charles T. Terry made his argument before that committee it would probably have held the Weber bill as the Apgar bill was held. Mr. Terry informed the committee on internal affairs that the retaliation measure would do no good and it would only hit the two States mentioned above, and that in New Jersey the association's representatives had succeeded in convincing the authorities of the unwisdom of their law, and Mr. Frelinghuysen was preparing to repeal the objectionable clause.

Other Attempts in Automobile Law-making.

The bill of the late Assemblyman Stanley, to establish a State automobile commission to take care of the registration of automobiles and create a new State department with a legal end represented by a counsel at a fat salary, and a retinue of clerks to enforce the motor-vehicle law, is still in ways and means committee, where it died last year and where it is liable to remain.

That freak proposition of Assemblyman Stevenson to amend the motor-vehicle law to provide for a system of taxation of motor-vehicles by taxing each \$2.50 per seat in said vehicle was torn apart artistically and completely as a legal proposition and as proper legislation of any sort by Attorney Charles T. Terry,

who appeared before the Assembly committee on taxation for the New York State Automobile Association and the National Association of Automobile Manufacturers last week. It is an indefensible proposition, ridiculous in its terms, unconstitutional in form and altogether drastic and unusual in its penalty features. It is still in the committee, where it went on introduction, and even should the committee report it there is little chance of its being seriously considered.

Another vicious bill is the Hamn amendment to the town law, which has not been reported from the internal affairs committee, where a hearing was given on it last week. This bill in brief would confer upon any municipal corporation, such as a town, village or city, the right to enact its own rules and regulations for the use of public highways by motor-vehicles, and is an impossible proposition. Attorney Terry told the committee on internal affairs, and forced several of its members to acknowledge the justice and reasonableness of his contention, that no motor vehicle could use the highways at all under such conditions, as the bill sought to establish with a new and strange set of regulations on either side of an imaginary line dividing two towns or a town and a village. The legislators were insistent on some legislation which should properly restrain the automobilists who recklessly violate all rules of the road and take delight in causing discomfort and injury to others and showed it in their remarks on this bill at the hearing. But Attorney Terry argued that their proposed local regulations would not accomplish it, and that there was plenty of law now on the statutes, and the trouble was that those complaining did not learn its provisions and take proper means to enforce it. The same complaints at times could be made against reckless drivers of horses, both at night and in the daytime, but that did not warrant the enactment of oppressive, unjust and restrictive laws to govern the whole class of horse drivers, nor should it govern the minds of legislators in framing laws for the government of motor cars on public highways. The bill was not reported.

Another of the bills still in committee is the Northrup bill amending the motor-vehicle law to provide that "No person shall operate a motor vehicle on a public highway that is geared to run at a rate of speed greater than one mile in four minutes." This bill is in the general laws committee of the Assembly, where it was referred on introduction.

A measure introduced this week in the Assembly requires that automobiles be retained as security for the appearance of the person arrested for violating the law.

CONCERNING THE PROPOSED ILLINOIS LAW.

SPRINGFIELD, ILL., Feb. 25.—Some members of the Illinois legislature are objecting to certain provisions of the automobile bill introduced early in the session by Senator Humphrey. Opposition is heard particularly against a portion of Section 13 of the bill, which provides that "no city, town, or village, or other municipality shall have power to make any ordinance, by-law, or resolution limiting or restricting the use or speed of motor vehicles, and no ordinance, by-law, or resolution heretofore or hereafter made by any city, village, or town, or other municipal corporation within the State, by whatever name known or designated, in respect to or limiting the use or speed of motor vehicles shall have any force, effect, or validity, and they are hereby declared to be of no validity or effect."

The bill, however, would have motor vehicles used for public hire regulated, a provision in this respect reading "that nothing in this act contained shall be construed as affecting the power of municipal corporations to make and enforce the ordinances, rules and regulations affecting motor vehicles which are used within their limits for public hire."

A. A. A. TOURING BOARD REPRESENTS 32 STATES

THE Touring Board of the American Automobile Association for the current year has been announced by President W. H. Hotchkiss. It comprises 77 members and represents 32 States. While such a board in ordinary circumstances would prove unwieldy, it is understood to be the intention of Chairman F. B. Hower to divide the board up into numerous committees, each charged with some function and work important to the motorists of the country.

Chairman Hower has called a meeting of the board for Buffalo, March 1, at which time it will undoubtedly adopt board rules and subdivide its work. Among the representative motorists on this board are Paul H. Deming, Philip S. Flinn, H. W. Smith, J. C. Kerrison, Waldron Williams, L. E. Myers, Isaac Starr. The complete list follows:

American Automobile Association—Touring Board—1907.

CHAIRMAN, F. B. Hower, 760 Main street, Buffalo, N. Y.
SECRETARY, Dal H. Lewis, 760 Main street, Buffalo, N. Y.
CALIFORNIA—L. P. Lowe, 21 Presidio avenue, San Francisco; Chas. B. Hopper, 402 Laughlin Bldg., Los Angeles, Cal.
COLORADO—Dr. W. H. Bergtold, 610 California Bldg., Denver, Colo.
CONNECTICUT—Geo. W. Beach, 54 Main St., Hartford; W. L. Hatch, New Britain; Frank Miller, Atlantic Hotel, Bridgeport.
FLORIDA—Geo. E. Sebring, Daytona; Fred E. Gilbert, Jacksonville.
GEORGIA—Frank B. West, Macon.
ILLINOIS—A. D. DeMange, Bloomington; H. D. Grider, Decatur; L. E. Myers, 1117 Monadnock Bldg., Chicago; L. F. Hoy, Woodstock; N. M. Van Sicklen, 309 Michigan avenue, Chicago; F. H. Pietsch, Eighteenth and Canalport avenue, Chicago.
INDIANA—Herbert H. Rice, care of Pope Motor Car Co., Indianapolis; J. A. Spekenhler, Richmond; E. C. Briggs, Box 154, South Bend.
IOWA—A. H. Ruebsam, Davenport; Harold R. Wells, Des Moines.
KENTUCKY—Pike Campbell, Fifth Avenue Hotel, Louisville.
LOUISIANA—Hart D. Newman, New Orleans.
MARYLAND, Frank W. Darling, Pikesville; W. B. Littleton, Hagerstown.

MAINE—Chas. C. Adams, Portland.
MASSACHUSETTS—J. C. Kerrison, care the "Boston American"; R. C. Guptill, Maiden; L. H. Greenwood, Gardner.
MICHIGAN—Paul H. Deming, 128 Lafayette avenue, Detroit; C. S. Mott, Flint; H. E. Shiland, Jackson; J. R. Jackson, Grand Rapids; Edwin S. George, Detroit.
MINNESOTA—Geo. S. Daggett, Minneapolis.
MISSOURI—Jas. G. Butter, 4484 West Pine Boulevard, St. Louis; W. W. Cowen, 307 Board of Trade Bldg., Kansas City.
NEBRASKA—D. C. Bradford, care the Bradford Kennedy Co., Omaha.
NEW HAMPSHIRE—Herbert O. Prime, 61 Union street, Portsmouth.
NEW JERSEY—Chas. D. Cook, Paterson; Geo. Frisbie, Asbury Park; Henry W. Leeds, Atlantic City; Chas. S. Van Syckel, Trenton; Geo. E. Blakeslee, 2565 Boulevard, Jersey City.
NEW YORK—F. E. Barnes, Binghamton; J. P. McMurich, Oswego; R. H. Johnston, New York; Augustus Post, New York; Robt. E. Hopkins, Tarrytown; Howard Martin, Albany; Geo. H. Leonard, Auburn; F. M. Fast, Geneva; G. E. Mosher, Rochester; Chas. Jerome Edwards, Brooklyn; R. B. Billings, 211-2 Summit place, Utica; Waldron Williams, 254 West End avenue, New York; H. W. Smith, 701 East Washington street, Syracuse.
NORTH CAROLINA—Walter Sprunt, Wilmington.
OHIO—Foster H. Bradley, Cincinnati; Thomas Curtin, care the Curtin Williams Co., Columbus; F. E. Avery, 1197 Franklin avenue, Columbus; Chas. N. Coit, Cleveland; C. Gordon Neff, 3518 Teleford avenue, Cincinnati.
PENNSYLVANIA—Edw. Kneeland, 2301 Farmers' Bank Bldg., Pittsburg; Chas. J. Swain, Philadelphia; H. F. Rawlin, P. O. Box 472, Harrisburg; Isaac Starr, 240 Dock street, Philadelphia; Philip S. Flinn, 320 Diamond street, Pittsburg.
RHODE ISLAND—Elliott Flint, 212 Union street, Providence.
SOUTH DAKOTA—F. D. Fitts, Madison.
TENNESSEE—S. T. Carnes, 316 Tennessee Trust Bldg., Memphis.
TEXAS—G. A. C. Haiff, San Antonio.
VERMONT—W. H. Riddle, Cottage street, Rutland.
WASHINGTON—Alfred Bornstein, 315 First avenue, South Seattle.
WEST VIRGINIA—W. E. Minghini, Martinsburg.
WISCONSIN—Jesse L. Potter, Milwaukee; Richard T. Robinson, Racine.
VIRGINIA—Frederick Lewis, 510 Atlantic Trust Bldg., Norfolk.

CHICAGO WANTS THAT A. A. A. TOUR IN SOME MANNER

CHICAGO, Feb. 25.—The movement to have the Glidden Tour end in Chicago is gaining new supporters daily. The Chicago Athletic Club and the South Shore Club have now joined hands with Chicago Automobile Club and the Chicago Motor Club in an effort to secure the honor for Chicago. Both the Athletic Club and the South Shore Club would throw open their respective clubhouses for the entertainment of the guests should the committee see fit to make Chicago the objective point. The committee appointed last week by the Chicago Motor Club to endeavor to convince the Touring Committee of the wisdom of this choice of route has held several meetings, and is formulating plans upon which to act. This will include the extending of invitations to the Chicago Golf, Glenview and Onwentsia clubs to join with the Athletic, South Shore and Chicago Automobile clubs in keeping open-house for the Gliddenites should the committee end the tour in Chicago.

Activity of the Trade Association.

During the week the plans of the Automobile Trade Association for placing guide posts along the principal roads leading to Chicago and used by automobiles have assumed definite form. It is proposed to use a 2x24-inch signboard on a 5-foot angle iron post set in cement. The cost of these signs and the surveys which will have to be made will bring the cost of each sign up to at least five dollars for every one placed.

The second annual meeting and election of officers of the Trade

Association will be held next Thursday evening. The ticket nominated as the "members' ticket" is as follows: President, Joseph F. Gunther; vice-president, W. J. Mead; treasurer, W. L. Githens; secretary, Thomas Hay. The officers and members of the Trade Association feel gratified with the results of its first year's work and look forward with hopefulness to the success of the contests which will be arranged for the summer in conjunction with the Chicago Motor Club. These include reliability, endurance, economy, and braking and skidding contests.

President Ira M. Cobe feels that these are red-letter days for the Chicago Automobile Club, as the membership is increasing by at least twenty each week.

MARYLAND CHAUFFEURS HOLD ELECTION.

BALTIMORE, Feb. 25.—At the annual meeting of the Chauffeurs' Club, which was recently held at the clubrooms in the Mount Royal Garage, the following officers were elected for the coming year: President, William Stevenson; first vice-president, A. R. Qualey; second vice-president, Fred Charpait; secretary and treasurer, W. D. Wehland; board of governors, William Stevenson, William Thornberg, John Harris and W. T. Carter.

Following the election of officers an enjoyable smoker was held. The club was organized in 1905 with a few members, and since then its membership has been considerably increased.

BUFFALO'S SHOW A RECORD BREAKER.

BUFFALO, N. Y., Feb. 23.—Dai H. Lewis, manager of the Fifth Annual Show of the Automobile Club of Buffalo, said to-night: "This has been the most satisfactory exhibition since shows were held in Buffalo, and it means that there will be a similar event in 1908 on a much larger and grander scale. The attendance was larger and the sales were a substantial increase over a year ago."

Amid the screech and din of hundreds of automobile horns, the show came to its end in Convention Hall to-night. Thousands of Buffalonians attended the show every night, and delegations came from Rochester, Syracuse, Toronto, Niagara Falls, Lockport and small cities. "Sold" signs were many, and every exhibitor had one or more on the machines he displayed. So successful has been the 1907 exhibition that the talk of abandoning local automobile shows, which was the rumor several weeks ago, has dissipated, and the 1908 automobile show is already assured. The Great Arrow cars had many admirers, and some sales are reported as a result of their presence in the hall. The Thomas Flyers also called forth an abundance of admiration, while many persons desiring horseless transportation gazed admiringly at the Babcock electrics. The non-stop Thomas was on exhibition a part of the week, and the Thomas Vanderbilt car was also shown. The Great Arrow, which won the Glidden trophy, was shown by the Pierce Company.

MABLEY FAVORS ANOTHER OUT-DOOR SHOW.

When approached on the subject of an "automobile trade show week," in accordance with the suggestion made at the last meeting of the New York Automobile Trade Association, Carleton R. Mabley, of Smith & Mabley, Inc., was not altogether enthusiastic for reasons that appear.

"Of course, like any other new and untried proposition, it is hard to say whether or not the plan would be a good one," he said. "My personal opinion, however, is that in view of the fact that the various New York representatives receive their new models at different times, it would be an awfully hard proposition to select a week that would suit even the majority. The outdoor show that was held last year under the auspices of the trade association, as far as I could learn, was very successful, inasmuch as the event was in its infancy, being tried then for the first time. Many things were brought to the notice of the association, which, if the show were held again, would be taken advantage of and bettered. Therefore, I feel that another outdoor show would be preferable to a spring show week."

GOVERNOR WILL OPEN MINNEAPOLIS SHOW.

MINNEAPOLIS, Minn., Feb. 25.—The Northwestern Automobile Show, to be held next week, is rapidly approaching completion as to detail of decorations and exhibits. The Chicago show decorations have been received and are being installed, and an elaborate scheme of adornment has been built up around them. An elaborate program in connection with the show has been laid out, including music by the Minneapolis Symphony Orchestra. In the evenings noted soloists will appear. Governor Johnson and Mayor Haynes of Minneapolis are to officiate at the opening of the show, Saturday, March 2.

The entire Northwest is tributary to Minneapolis and St. Paul in the automobile field, and dealers, owners and prospective owners from all parts of Minnesota, Wisconsin and the Dakotas, and as far west as Montana, will attend the exhibition.

NEW HAVEN'S SHOW TO BE HELD MARCH 21-30.

NEW HAVEN, Conn., Feb. 25.—Arrangements have been completed for an automobile exposition to be held March 21-30 in the Second Regiment Armory. All of the local dealers will be represented, some of them entering as many as eight or ten cars. The Bridgeport Motor Company will have an exhibit of motor boats and engines, and two other large Bridgeport firms will be represented.

CLEVELAND SATISFIED WITH ITS SHOW.

CLEVELAND, O., Feb. 23.—George Collister, manager of the Cleveland automobile show, to-night said: "This show has done its share in demonstrating to the public the promising present and the great future of automobiling. Local shows unquestionably are of substantial value to the dealers of the cities in which they are held."

All week long Central Armory has held interested crowds, afternoon and evening, and the exhibitors, with scarcely an exception, expressed themselves as thoroughly satisfied with the results that have been secured. The artistic decorating of the show, with its absence of signs in the center of the building, was an attractive feature which brought forth much praise. It was a case of the commercial instinct being subordinated so as not to interfere with the artistic conception of the decorator.

While Clevelanders buy cars made in other cities, it is a fact that the majority of them make their selections from the home product, all of which were well represented in the show, and of course included Winton, Peerless, White, Baker, Cleveland, Royal, Gaeth, and R. & L. electric.

One of the impromptu pleasant social gatherings of show week was a dinner in the Bohemian room of the Cleveland Automobile Club, at which George Collister and W. F. Sayle were the hosts of the occasion. Those present included D. J. Post, W. E. Metzger, J. W. Gilson, James Becker, "Gov." Fred Castle, O. J. Woodward, G. J. Bradley, J. Cramp, L. C. Boardman, T. J. Wetzel and A. G. Batchelder. The rooms of the Cleveland Automobile Club answered for a general gathering place every evening, and Secretary Asa Goddard, in behalf of the club, extended the hand of welcome to the many visitors. One of the recent subscribers to the club's fund for the building of a model highway in the suburbs of Cleveland was John D. Rockefeller, who gave substantially.

A. M. C. M. A. TO FATHER ENGINEERS' SOCIETY.

According to officers of the American Motor Car Manufacturers' Association, the business of building automobiles is the only great industry that has no organization whose avowed purpose is general scientific research of the subjects of most interest to the members of the industry supporting it. That is, there has not been up to the present time any organization or society on this order that is open to all who wish to enter, regardless of trade affiliations. With this in mind, the American Motor Car Manufacturers' Association plans to foster an organization to be known as the American Society of Automobile Engineers. The members of the former will form a nucleus for the new organization, any designer of known ability being afforded an opportunity to participate in its meetings, and membership being open to all automobile engineers, whatever their connections may be.

It is expected that General Manager Alfred Reeves will issue a call for a meeting to organize the new society within a very short time. In addition to this, the A. M. C. M. A. is planning the establishment of a laboratory to further a higher grade of work of a similar character, the benefits of this, however, being confined to the membership of the organization. An option has been obtained on an old factory building at Yonkers, N. Y., and it is expected that the negotiations now under way will shortly be brought to a successful culmination, in which case a lease of the building will be taken and a complete plant for chemical and mechanical tests will be installed. Work on both the projects in question will be pushed, it being intended to hold the first meetings of the new organization during March, as it is planned to make them bi-monthly during the busy season of the year.

BOUGHT CARS OF HOME MANUFACTURE.

SPRINGFIELD, MASS., Feb. 25.—The Board of Fire Commissioners has decided to place an order for two 30-horsepower Model H Knox machines for the use of the chief and deputy chief of the department. The order was placed through Charles R. Culver, the city sales agent.

DAVID L. CANNON A PROGRESSIVE MICHIGAN AEROCAR OWNER.

AN UP-TO-DATE MICHIGAN STOCK BUYER.

DETROIT, MICH., Feb. 25.—With steady strides, the automobile is rapidly pressing forward and is being used to shorten distances and time in almost every line of work. One of the very latest uses for an automobile is novel indeed. David L. Cannon, a drover and stock buyer in the eastern part of Michigan, uses an Aerocar for getting about the country and looking up stock among the farmers. Many miles in a day can be covered in this manner, and the time spent between the different homes is practically nothing as compared with what it was when he made the same trip with a team of horses. It is during the winter months that the greatest rush of business is on. With his air-cooled car he drives up to a farm house, shuts off the power, leaving the machine anywhere, and is soon engaged in trying to make a deal with the farmer for his fatted cattle. This drover is a student of human nature. He has learned that one of the nearest ways to a man's heart is through his stomach, but that you can get pretty close by pleasing him. It is, therefore, a common occurrence to see him spinning along the road with the car filled with broad smiling agriculturists, who, perhaps, had never before ridden in a horseless vehicle. After such a ride very few objections are made even if Dave's price for beef on the hoof is not quite what they had expected.

The accompanying picture shows this up-to-date drover on a return trip, driving a herd of young cattle. He rides in his car, toots the horn, and, with his two Collie dogs, drives his purchases in a manner that is in keeping with the enterprising spirit of the man and the times.

MISS ZABELLE ENJOYING A CONSTITUTIONAL IN HER POPE-TOLEDO

AUTOMOBILING AS A WINTER PASTIME.

In its earlier days the automobile was a fair-weather bird pure and simple. Rain was sufficient to cause it to stay at home, and mud proved such a strong deterrent to its underpowered engine that pleasure was only to be found beneath fair skies and along smooth roads. At the head of the column is shown Miss Flora Zabelle taking a constitutional in Chicago's parks with the aid of her new 50-horsepower 1907 Pope-Toledo, while below, the leading ladies of one of the companies now playing in New York, Miss Agnes Cain Brown and Miss Lillian Hudson, are shown in Miss Brown's new 22-horsepower Berliet, which she has used regularly to take her back and forth between her home at Tarrytown-on-the-Hudson and the theater in the city.

Major C. J. S. Miller is seen in his new American Mors. Automobiles have been his hobby, and it is not too much to say that he has probably owned as large a number and as great a variety of different makes of cars as any amateur on this side of the Atlantic, not even excepting Colonel John Jacob Astor, who also has a strong penchant that way. For the first ten days of his American Mors ownership the Major ran up a total of 600 miles, all of which were through snow and no little part of it through heavy drifts, which were negotiated without difficulty.

Equipped with chains on the drivers to procure the necessary traction, the modern automobile no longer fears the snow. It is a detriment, to be sure, for six inches or more of the "beautiful white" constitute a speed-reducer that has a marked effect on even the most powerful of cars, while heavy drifts frequently call for a shift of gear even on the level.

MAJ. C. J. S. MILLER WINTER RIDING IN HIS AMERICAN MORS

MISS AGNES BROWN'S BERLIET WHICH PLOUGHS THROUGH SNOW.

A 1907 MOON: DESIGNER L. P. MOOERS AND J. W. MOON.

MOTOR PARTS COMPANY, W. W. BURKE, MGR.

With headquarters at 25 West Forty-second street, New York City, a capitalization of \$100,000, and with W. W. Burke as its president and general manager, the Motor Parts Company is announced as a selling corporation partaking of the nature of a co-operative buying company. Mr. Burke will be well remembered as manager of the Electric Vehicle Company's Boston and New York branches, and associated with him are some prominent automobile tradesmen of wide experience.

"One of the greatest evils in the automobile business has been the taking of orders by parts people in excess of their production," said Mr. Burke, "and this has resulted in manufacturers being held up for their parts. A maker of parts would take orders for 6,000 or 7,000 sets to cover himself thoroughly, when he knew that his output would not be more than 5,000 sets. It was to remedy this trouble, besides securing inside prices, that a number of prominent manufacturers have interested themselves in this idea, which I have had in mind for more than a year. The company will handle only the very best products and only after they have been tested out in our laboratory at Yonkers.

"It is the idea of those interested to push only one article in a line, and to be able to assure our customers that the article in question is the best. The company intends to take outputs on a reasonable basis, thus relieving factories of the expense of selling departments. The accounts which we start with are such as to give the company a standing at once.

"The Motor Parts Company will be a sort of clearing house between the maker of the parts and the builder of the automobile, with the former being assured of a sale for his output and the latter being assured of deliveries and proper prices.

EZRA KIRK A TOLEDO GARAGE MAN.

Ezra Kirk, a well-known cycle trade graduate to automobiling, has resigned as sales manager of the E. R. Thomas Motor Company, of Buffalo, and in company with a brother will conduct a mammoth garage in Toledo, Ohio. Mr. Kirk's old home is in Toledo, from which city he went to Buffalo.

R. H. CRONINGER TO SELL PENNSYLVANIA CARS.

R. Harry Croninger, formerly Stoddard-Dayton sales manager, has gone with the Pennsylvania Auto Motor Company, Philadelphia, to act in a like capacity. It is understood that the Pennsylvania company intends to make extensive additions to its factory in the near future.

NOTABLE ADDITIONS TO EMPIRE TIRE STAFF.

H. H. Githens and W. R. Whitlock are well-known additions to the selling staff of the Empire Automobile Tire Company, of Trenton, N. J. Both were formerly of the G & J Tire Company.

C. A. BENJAMIN TO BE AEROCAR ADVOCATE.

C. Arthur Benjamin, one of the pioneers of the automobile trade, first with the Locomobile Company of America, then with the H. H. Franklin Manufacturing Company, and now leaving the sales managership of the Babcock Electric Carriage Company on March 15, will become vice-president and general manager of the Aerocar Company, of Detroit. Mr. Benjamin's change of base was somewhat unexpected, but it is understood that the inducements offered were of a substantial character.

WARNER LEAVES MUNCIE PARTS COMPANY.

H. L. Warner, up to recently connected with the Muncie Auto Parts Company, Muncie, Ind., has just severed his connection with that concern, and will organize a corporation to be known as the Muncie Gear Company, which will manufacture bevel and spur gears, sliding-gear transmissions of both types, disk and cone clutches, control levers and the like.

JAMESON GOES WITH DAYTON INTERESTS.

Charles Jameson, late of the Orlando F. Weber Company, Chicago, has given up the retail end of automobile selling for the wholesale, having just gone with the Dayton Motor Car Company as sales manager, and will from now on push the Stoddard-Dayton cars. He takes the place of R. Harry Croninger, who resigned recently to go with a Pennsylvania concern.

L. D. PARKER, BILLINGS & SPENCER DIRECTOR.

At the annual election of the Billings & Spencer Company, Hartford, Conn., which was held last week, L. D. Parker, formerly president of the Hartford Rubber Works Company, was elected a director to fill the vacancy caused by the death of Franklin Clark. All the other officers who served during the past year were reelected.

HOW FRANKLINS ARE SHIPPED NOWADAYS.

SYRACUSE, N. Y., Feb. 25.—The photograph gives a very clear idea of the cars now being furnished by the Lackawanna Railroad for automobile purposes. In construction these cars are cut along the line of furniture and wagon cars, except that the doors, instead of being directly opposite one another, are staggered in such a way as to make extremely easy the loading of motor cars. In size they are roomy, being high and wide, the inside measurements being 40 feet long, 13 feet 11 3-4 inches wide and 9 feet 4 5-8 inches high. These measurements are such as to admit of loading the largest Franklin cars with the top up, as will be seen in the photograph.

AUTO CAR NOW SUPPLIED BY LACKAWANNA R.R.

IN AND ABOUT THE AUTO GARAGES

ONE of the popular garages for automobilists touring in Northern New Jersey is that of the Perkins Automobile Company at Rockaway. This thriving Jersey town is situated on the Rockaway river, near Dover, on the road leading out from Newark to the north of the Oranges, and through Montclair, on

A MODERN GARAGE AT ROCKAWAY, NEW JERSEY.

the direct route to Port Jervis, N. Y. As will be noticed by the photograph, the garage is roomy, and the entrance arrangements show an appreciation of up-to-date requirements. The Perkins company are also agents for the Corbin car in that vicinity.

Rochester's Big Garage to Be Extensively Enlarged.

ROCHESTER, N. Y., Feb. 25.—Fulton Avenue Motor House has purchased the property adjoining it in the rear, and the buildings on the newly acquired property will be connected with the Fulton, thereby making one of the largest garages in the city. The property purchased has a frontage on Lake avenue of 92 feet, and is 225 feet deep. Lake avenue is one of the principal business and residence streets of Rochester, and is the main boulevard to Lake Ontario. During 1907 the business will be conducted under the name of "The Autohospital," as the management of the concern has been somewhat changed. Howard M. Stone, who has been exclusive manager for the past two years, has taken into partnership with him Charles D. Barrows, who was connected for four years with the Knox Automobile Company.

A Modern Garage for Vancouver Island.

VICTORIA, B. C., Feb. 20.—The Pilmey Automobile Company will have its new garage on James Bay ready for occupancy on May 1. The total cost of the building is estimated at \$10,000; there will be housing room for about forty cars. Advantage will be taken of the growing tourist traffic on Vancouver Island to run an automobile tally-ho with a capacity for carrying sixteen persons. Trips will be made at stated intervals during both winter and summer to various places of interest. The company, which will handle English cars exclusively, has a capital stock of \$100,000, subscribed by Victoria people.

Winnipeg to Have a Modern Garage at Once.

WINNIPEG, MAN., Feb. 20.—Canada's most progressive city is to maintain its reputation by shortly erecting the most modern garage that the entire Dominion can boast of. Though not as well situated regarding population or opportunities for the use of the automobile, Winnipeg is about set out to astonish its sister

cities further east. The new building is to be erected for Joseph Maw, and construction will be started as soon as the weather permits, which in the Northwest means much later than here. The property, which has a frontage of 66 feet and a depth of 200 feet, is now occupied by a livery stable, so that it will be another instance of horse giving way to the automobile. The construction will be of steel and brick, and though the entire area will be covered by the garage there will not be a post to obstruct the floor. The Maw Company, owners of the new garage, have just received a new 12-passenger sightseeing 'bus which will be put into active service immediately.

Increased Garage Facilities at Burlington, Vt.

BURLINGTON, Vt., Feb. 25.—Plans have been completed for the erection of a new building which will double the present car capacity of the Van Ness garage, in this city. When completed there will be accommodation for about twenty-seven cars. A feature of the garage which will be welcomed by tourists visiting Burlington will be the twelve-passenger Rapid sightseeing automobile recently purchased by Capt. E. P. Woodbury, of the garage. It will be used on excursion parties, and will also make regular trips to the wharf of the Champlain Transportation Company, on Lake Champlain, in place of the horse-drawn 'bus previously used. The Van Ness garage now has the agency for Western Vermont of the Rapid, the Reo, and the Premier cars.

GARAGE NOTES FROM ALL OVER.

Yakima, Wash.—The Yakima Garage and Automobile Company of North Yakima, Wash., has been incorporated, with a capital stock of \$5,000, by R. H. and A. F. Mitchell.

Houston, Tex.—On a recently purchased lot on Travis street, just above Texas avenue, Levy Brothers are building a brick structure designed as an automobile garage.

Ft. Dodge, Ia.—W. W. Eggers, formerly of Nora Springs, has signed a lease of the Crawford building on Public square, where he will open and operate an automobile garage.

Los Angeles, Cal.—A. J. Crawford has secured the contract to build a two-story brick building at the southwest corner of Main and Fifteenth street for George Wilson King. The lower story will be arranged for an automobile garage.

Philadelphia.—J. E. & A. L. Pennock, of this city, have just completed plans for a three-story and basement garage to be erected at 216-220 North Broad street. Construction will probably be undertaken as soon as the spring opens.

Canton, Ill.—James Duvall and A. M. Champ have just completed the purchase of a lot 40 by 80 feet on East Pine street, and will immediately begin work on the erection of a one-story garage building. This will be of brick, and will cover the entire lot.

Toledo, O.—Mirk Brothers have leased the ground floor of the building about to be erected on Jefferson street next to the Zenobia building, and will fit it up as a garage as soon as ready for occupancy. It has a frontage of 50 feet and a depth of 100. Construction has already been begun.

Wilmington, Del.—On April 1 the Wilmington Automobile Company, which now occupies half of a large building at Delaware avenue and Tenth street, will take possession of the re-

mainder of the building, thus more than doubling the present floor space. A new feature will be separate doors for entering and leaving the garage.

Chicago.—The automobile business is about to invade the residence district in Michigan avenue, south of Twenty-sixth street, Richard T. Crane having sold his large vacant holding in this block to purchasers who plan to erect upon it a five-story building for the purpose indicated. The proposed building will cost about \$100,000. The names of the purchasers are withheld.

Des Moines, Ia.—The garage of the Iowa Automobile Company is being entirely remodeled. The south twenty-two feet of the large room is being partitioned off for a retail sundries room. A new office will be built and the old one torn down. A new front will be put in and a new floor laid, and several of the center supports will be removed to give more room. New machinery is being added to the repair department.

Washington, D. C.—The corporation commission of Virginia has granted a charter to the Dupont Garage Company, of Alexandria, Va., which will conduct a general automobile business in Washington, D. C. The capital stock is to be not less than \$29,000 nor more than \$50,000. The officers and incorporators are as follows: W. S. Washburn, president; G. P. Sacks, vice-president; C. F. Sponsier, secretary; R. A. Klock, treasurer. The company has a large garage on M street, in Washington, and handles the Cleveland, Rambler and Orient.

Charleston, S. C.—The Army Cycle Manufacturing Company, the first concern to introduce gasoline cars in this section, is now planning to erect a modern garage adjoining its present establishment at 130-132 Meeting street. The building will be of brick, with cement floors, and will have a plate glass front. Included in its equipment will be a modern repair shop fitted out with machine tools of every kind needed for doing auto repair work. Among the recent sales made by this concern has been one of a four-cylinder Buick to the local fire chief.

■ MANY TOLEDO GARAGES AND AGENCIES.

TOLEDO, O., Feb. 25.—Local garages are getting in their stock of 1907 cars for prospective purchasers who are becoming more numerous every day. The Kirk Brothers have on hand a goodly number of Thomas Flyers at their Jefferson street garage, and incidentally it might be stated that before the season progresses very far this company will be installed in one of the finest garages in the city. C. S. Ashley is now starting the erection of a building on Jefferson street, between Tenth and Michigan streets, which is to be occupied by Kirk Brothers as a showroom. It will have a floor space of 50 by 100 feet.

Adjoining the site of the Kirk Brothers' new garage is located the Lichtie garage, which will continue to handle the Cadillac machines. To better display his automobiles, Mr. Lichtie has just had a large electric sign placed in front of his garage.

The Jackson machine will be introduced to Toledo buyers by the Rivers-Jacoby Automobile Company, which is located on Monroe street in the residence section. Along with the newcomer, the concern will handle the Rambler. Both stocks are well represented, but both are to be greatly increased as soon as the floor space of the company can be enlarged by an addition.

The Atwood Automobile Company, also located on Monroe street, will act as sales agents for the Elmore, Franklin, Pope-Waverley and Pope-Hartford cars during the coming season. The company has the largest garage in the city, being able to house 125 cars. Shipments of all these cars have been received.

The Central Automobile Company, on Ontario street, not far from Jefferson, will sell the Maxwell cars, a large consignment having just arrived. The company will also handle the Mitchell.

The Toledo Car Company, on Madison street, will act as sales agents for the Pope-Toledo cars and, with the home of the car in this city, the company ought to have something of an advantage over its rivals.

The new garage of the White Company, which the Spitzer Brothers are erecting for it at 1211-15 Madison avenue, will be open within a few days, and the White cars will be shown there.

ATLANTA HAS LARGEST SOUTHERN GARAGE.

ATLANTA, GA., Feb. 25.—There has been a considerable shake-up in the Atlanta automobile trade since the beginning of last season. The Atlanta Automobile Co., at that time a large concern, has been absorbed by the Capital City Automobile Co., a stock company backed by very considerable capital. This company has secured the old Peachtree Auditorium and fitted up the largest garage in the South. The cars carried by the Capital City Co. are the Stevens-Duryea, Peerless, Stearns, Franklin, White and Buick.

In addition to this corporation there are three other dealers—F. C. Steinhauer, 56 Edgwood avenue, who sells Thomas cars; James B. Todd, 322 Peachtree street, who handles the Stoddard-Dayton line, and John E. Smith, 122 Auburn avenue, who has the agency for the Reo line.

A "MOOSE" COLUMBIA DINNER AT HARTFORD.

HARTFORD, CONN., Feb. 28.—Sixty members of the office and factory force of the Electric Vehicle Company attended the annual moose dinner, the *picée de resistance* of which was supplied, as usual, by George E. Risley, of the sales department, who once a year travels to the wilds of Maine and returns therefrom with a moose. Three consecutive seasons has Mr. Risley been successful, and the third affair, held at Parson's Café, was the banner one of the series. Each course on the menu bore the name of some part or accessory of a motor car, and "Deacon" Henry A. Castle made a versatile toastmaster. Speeches and recitations were rendered by Messrs. Castle, Higgins, Hill, Bee, Wilson, Hathaway, Whitney, Nuckols, Fisher, Strout, and Risley, with songs sung by Messrs. McAneeny, Mertens and Hathaway. While the menu bore the caption of "All Speed Limits Removed," the autoists observed a reasonable pace and none was apprehended for scorching, or flooding his carbureter with alcohol.

DURYEA POWER COMPANY GOES UNDER.

What has long been predicted by the business-wise, if mechanically unlearned, has at last come to pass. Charles E. Duryea's persistent adherence to ideas that were beautiful theoretically and mechanically, but not practical from the point of view of the public demand, has brought him to financial ruin. How the company has managed to exist has long been a matter of wonder, so that its downfall is not wholly unexpected. It has always been hampered for lack of capital, and was finally compelled to go to the wall. The Pennsylvania Trust Company has been appointed receiver, and it is rumored that Herbert N. Sternbergh, of Reading, Pa., one of the stockholders, will buy in the plant and consolidate it with that of the Acme Motor Car Company, which he recently bought from the receiver of that concern.

BRISCOE MFG. CO. DENY UNAUTHORIZED RUMOR.

DETROIT, MICH., Feb. 25.—Owing to the statements which have been circulated among the trade that the Briscoe Manufacturing Company, of Detroit, Mich., intends to discontinue its radiator business, it has been found necessary to issue an official denial. The mistake probably arose from the fact that the company has discontinued the manufacture of galvanized ware, stoves, etc., this being rendered necessary in order to make room for the manufacture of radiators and other automobile parts. The Briscoe Manufacturing Company is now making plans for a larger business. In addition to the new brass foundry, a complete machine shop for automobile work has been opened.

BRIEF ITEMS OF NEWS AND TRADE MISCELLANY

John Duer, of Hastings, Neb., has disposed of his automobile business to C. L. Jones & Company, who will occupy the First street garage.

In the issue of *THE AUTOMOBILE* for January 31 the Holsman Automobile Company's machine was described as having "rope" drive. The company states that this should be "steel cable" drive.

The DAC Automobile Supply House controlled by Wyckoff, Church & Partridge, has changed its name to the W. C. P. Automobile Supply House, and Raymond H. Weaver, well known to the local trade, has been appointed manager.

John C. King, of Chicago, has ordered a 35-horsepower Fiat chassis to be fitted with a four-seated runabout body. He will take delivery of this car this month at Turin, Italy, and will spend the entire summer touring about Europe.

At a recent meeting of the D. C. Stover Company of Freeport, Ill., it was decided to change the name of the firm to the Stover Motor Car Company. For some time the engineers of the company have been busy on an engine for railroad and track inspection trips.

An order has been received by the Ajax-Grieb Rubber Company for 5,000 sets of tires for the well-known runabouts built by the Ford Motor Car Company. The tires will be shipped in pro rata lots during the next seven months. The Ajax people now occupy the three floors in the building at Broadway and Fifth-seventh street, with the factory at Trenton, N. J.

M. C. Hutto and Claude Nolan, of Jacksonville, Fla., have closed a deal with the Clark Auto & Launch Company whereby they become the sole owners of the plant, comprising fourteen second-hand automobiles, machinery, tires, tools, etc., and two new touring cars. This combined equipment will give the firm one of the most extensive repair shops and supply stores in the South.

While standing outside the Coliseum at Chicago at the end of the show week, the Stearns demonstration car was stolen. The automobile was a 30-60-horsepower model, bearing factory No. 202. It was painted with red sear panels, black under body and red running gear, and was equipped with a folding glass front. The F. B. Stearns Company would be glad to hear from any person having observed this car.

The limousine body building department of the Packard Motor Car Company, of Detroit, having completed its work of building the season's output of limousines for Packard "thirty" chassis, the company has decided to build a special lot of limousine bodies for summer delivery. These will be of standard Packard design and will be interchangeable with the touring body on either the Packard "twenty-four" or the "thirty."

One of the old landmarks of Main street, Buffalo, the Sheldon homestead, is to be removed to make room for a new automobile store for the Imperial Motor Company, of Buffalo, of which C. B. Penny is president. The building, which will be two stories in height, will have

a frontage from 1094-1100 Main street and a depth of 436 feet to Linwood avenue. A selling business only will be carried on, the building not to be used as a garage.

The Court of Common Pleas of Berks county, Pa., has entered a decree conveying to H. M. Sternbergh, of Reading, Pa., the entire property and assets of the Acme Motor Car Company of that city, terminating the receivership of D. J. Driscoll, which commenced in July, 1906. The price paid was \$66,000, and creditors will be paid in full therefrom by the receiver. Pending the organization of a new corporation the Acme Motor Car Company's business is continued without interruption by the purchaser.

A tester for the Wayne Automobile Company, of Detroit, Mich., who was discovered with the nose of his machine firmly planted against the factory wall, the high gear in and the rear wheels spinning merrily over the road, retains a rather unpleasant memory of the result of his inventive genius. He was trying to demonstrate to his own satisfaction the pulling powers of the engine and the staying qualities of the clutch. However, so pleased were the officials of the company with the idea that it was decided to submit every car to the test before shipping.

"Captain the Hon." William Stanley, noting the difficulty of beginners and others in the matter of speed-gear changing, set himself to design a device which would automatically and efficiently perform the work, remarks an English exchange by way of introductory to a description of the mechanism in question. It further describes a test of the device, which is said to work "charmingly" and in a most amazing and satisfactory manner. A car that will dispense with the services of a driver altogether should be next in order.

According to the figures which have been compiled at Albany by a Rochester automobile agent, 1,525 automobiles have been licensed in Rochester up to February 15. The automobile man was put to considerable expense to get the figures from the State records and believes the following numbers of the makes in use in that city to be authentic: Cadillacs, 107; Columbia electrics, 135; Wintons, 75; Packards, 59; Fords, 56; Franklins, 55; Pops (Pope-Toledo, Pope-Waverley, Pope-Hartford), 51; Olds, 48; Columbus electrics, 32; Bakers, 21; Jacksons, 13; Royals, 13.

NEW AGENCIES ESTABLISHED.

W. C. Jaynes & Company, 721 Main street, Buffalo, N. Y., have been appointed agents for the Royal.

The McDuffee Automobile Company, of Chicago, will very shortly move into the new branch salesrooms and garage in Milwaukee.

The George Lowe Company, 509 Tremont street, has taken the Boston agency for the American Mors, manufactured by the St. Louis Car Company.

The International Automobile Company, Montreal, is about to erect a \$40,-

000 garage on St. Catherine street and will represent in Canada the Dragon car, and for Eastern Canada the Wayne and Gale lines.

New agencies established by the Wayne Automobile Company are as follows: A. F. Solliday, Milwaukee, Wis., entire State of Wisconsin; Johnstown Automobile Company, Johnstown, Pa.; P. Pawler, Calumet, Mich.

W. W. Haskell has been appointed manager of the New York branch of the automobile oil department of the Alden Speare's Sons Company, of Boston. The New York branch of this firm is located at 654 West Thirty-fourth street.

Toronto, Can., has obtained a new automobile show room and garage, recently opened at 6 East Adelaide street by the Toronto Automobile Company. The new firm will handle all the well-known Pope models. W. R. Kicks is manager of the company.

Frank F. Weston, sales agent for the R. H. Smith Manufacturing Company, announces that his firm has leased the store, 1303 Michigan avenue, Chicago, to open a branch for the sale of the Springfield Motometer. W. L. Bowman will act as Western branch manager.

The Firestone Tire & Rubber Company will shortly open a Pittsburg branch at 5904 Penn avenue, East End, one square from the center of the "bunch." A complete stock of solid and pneumatic tires will be kept and a first-class tire repair shop will be installed.

A strong combination has been formed in New Jersey to handle the Lozier car in the eastern section of the State. Salesrooms have been opened at 17 Bank street, Newark, and it is proposed to establish branch headquarters in other localities. The members of the firm are C. Linkroum and L. W. Smelser.

Automobile dealers in Indianapolis, Ind., are constantly adding to their agencies and more than twenty-five foreign lines will be represented in that city this season. The Indiana Automobile Company has just taken the State agency for the Pope-Hartford, Thomas, and Baker Electric lines; the Gibson Automobile Company has contracted for the agency of the Logan Construction Company and will make a specialty of one and two ton trucks.

OLD CARRIAGE FIRM ENTERS AUTO BUSINESS.

The Hume Carriage Company, one of the oldest firms engaged in the carriage industry, has opened an automobile department in connection with its works at Amesbury, Mass. A specialty is made of all styles of high-grade automobile tops in leather, twill or khaki. Repair work and do-over of automobile bodies will in future be an important branch. The company will carry automobile patent bumpers, patent foot rests which can be raised or lowered to fit any person, patent folding seats for limousine and touring cars, as well as a full line of headlights, searchlights and lamps of the best makes.

INFORMATION FOR AUTO USERS.

Auto Jewelry Novelties.—Automobile jewelry is one of the important lines handled by Chas. E. Miller, manufacturer, jobber, exporter and importer, of 97-101 Reade street, New York. The jewelry line is a branch of a large automobile supply trade, and includes such

AUTOMOBILE INKSTAND.

articles as charms, hatpins, and fobs copied from the automobile and automobile parts. The latest of these interesting novelties is the automobile inkstand, illustrated herewith. The top of the car opens, revealing an ink well. Other articles made from the same model are an ash receiver, match holder, jewelry case and pin cushion. All these are finished in a rich ormolu gold or French gray silver, and the length is 5 1-4 inches and height 3 1-8 inches. The price in either style is \$2 each.

The firm's 1907 catalogue has just been prepared, and can be had upon request.

Novel Lock Switch.—With the constantly increasing spread of knowledge of how to operate automobiles, and particularly in view of the strong temptation held out to the unscrupulous chauffeur out of work to make way with a car standing at the curb, a lock of some kind becomes an absolute necessity. And the great trouble with any form of lock requiring a key is that the owner him-

BRANDOW LOCK SWITCH.

self most often mislays the key and has to smash the lock. To remedy this and provide a simple and effective lock which is proof against anyone but the owner or employee with knowledge of its working, Dr. Frank W. Brandow, of Pittsfield, Mass., has devised a simple combination lock. But unlike the usual article of this

kind, there is no dial or number plate, the lock being operated solely by the sense of hearing or touch. It is a click lock and it is only necessary "to count the clicks." It may be operated by one, two or three numbers and an almost endless number of combinations are possible. One turn of the lever shown disconnects the batteries and a revolution of the dial advances the lock bolt, short-circuiting the magneto. The lock switch is enclosed in a neat hard-rubber case and lists at \$10.

A smart, attractive booklet has been issued by the A. W. Harris Oil Company, of Providence, R. I., dealing with their famed oils. Printed in yellow, black and red, the booklet is gotten up with considerable skill and is of a catchy nature. Le Blon, one of France's crack drivers, Barney Oldfield and F. E. Stanley, America's speeders, give their opinion on these oils, and the compiler of the booklet sets forth the different qualities of the firm's products and gives advice on the most suitable grades to use for different weather conditions and on various types of engines.

Merkel Motorcycle.—Numerous changes and improvements have been effected in the 1907 model of the Merkel motorcycle, manufactured by the Merkel Motor Company, Milwaukee, Wis. Wheelbase is six inches longer than formerly. The motor, 3 1-4 bore by 3 inch stroke, developing three horsepower, is set in an upright position and carried in the loop portion of the main frame tube. An entirely new float feed compensating carbureter, designed to give considerable variation of speed, has been utilized. Engine control is a grip device devoid of any angles or parts liable to wear loose or rattle. It is entirely inclosed in the inside of the handle bar, except that portion extending from the center portion of the main handle bar to the throttle lever of the carbureter. The Merkel type of suspension, so designed that it carries the weight of the rider entirely suspended on the springs housed within the rear stays, is retained as a feature of the new model. In addition a spring fork is now employed. A 1 1-4 inch flat, two-play belt is used, and the driving belt idler is so arranged that it can be adjusted while the machine is in operation and can be used in practically the same manner as

the clutch of an automobile to free the motor and allow it to run independently. The gasoline tank has a capacity for a 200 miles journey, while the lubricating supply is sufficient for 350 to 450 miles. An efficient muffler is provided, making the motor almost silent when under way.

Big 4 Spark Plug.—The spark plug put on the market by the Big 4 Spark Plug Company, 104 John Street, Detroit, is so named from the fact that it has four

CROSS SECTION BIG 4 SPARK PLUG.

electrodes, from which under all ordinary circumstances a flame is obtained from each point at one and the same time. Perfect insulation is obtained by the use of the best imported porcelain in two pieces, the front piece passing through the steel head, one-fourth inch, therefore giving no possible chance for the current to jump through from the central adjusting pin to the steel head. In this plug the large threaded bushing in the rear of the steel head, common to most plugs, is abolished. The steel pin, 3-16-inch in diameter, in the center of the plug, is that from which all adjusting and tightening is done. A special grade of wire is used for making the contacts, which has been proved by long tests not to corrode, scale or in any way break the spark.

1907 MODEL OF THE MERKEL MOTORCYCLE.

THE AUTOMOBILE

BOSTON, March 7.—And, finally, of the big shows comes Boston, with its Fifth Annual Automobile and Power Boat Exhibition, housed in spacious Mechanics Building and overflowing into Horticultural hall, and even then not having enough room for all comers. From Saturday night next to the following Saturday night the New England patrons of automobiles and motor boats will attend in thousands, and the allied industries will benefit to the extent of thousands of dollars in sales.

"Bigger, Better, Busier Boston" was the slogan that landed Boston's energetic mayor, John F. Fitzgerald, in the coveted place in City Hall, and since the campaign his alliterative war-cry has become almost indelibly associated with the commercial activities of the Hub. The phrase cannot be applied with greater truth than to this fifth show of the Boston Automobile Dealers' Association. Each one of the adjectives by itself, or the three as a unit, describe the collection of motor vehicles for land, and power craft for sea that has been assembled for the edification of New Englanders next week fully and completely.

That the Boston show is "Bigger" than any of its historic or immediate predecessors, here or elsewhere, needs only a brief and cursory examination of the halls to prove. Every foot, every inch even, of the exhibition space in the great halls of Mechanics Building, the largest of its kind in New England, and of Horticultural Hall, has been sold. Late comers who, though they moved heaven and earth, could not buy or beg floor space have had to be content to show their products on the side walls or in the aisles. And they consider themselves lucky to be a part of the biggest automobile show of the country. The automobiles have even invaded the precincts of Paul Revere Hall in Mechanics Building, a handsome apartment whose polished floor is rarely revealed except for dancing purposes. That this hall might be used required several special meetings of the trustees

of the buildings, and the bringing to bear of every possible influence by one of the oldest and largest automobile concerns in the country, which, through misunderstandings, had been shut out from obtaining space on the main floor. Up the avenue in Horticultural Hall the huge motor trucks look strange in the halls where the Boston public is accustomed to view rare orchids, roses and the other products of the best greenhouses of the State. More different makes of automobiles will be on exhibition at the Boston show than at either of the New York exhibits, and nearly, if not quite, as many as at the two combined.

That the show is "Better" than ever before cannot fail to be the verdict of the host of enthusiasts when it is admitted to the apple orchard and rose garden into which Manager Campbell has transformed the show buildings. Not only is the idea of the decorations unique, but it is effective, and the orchard in full bloom and the trellises loaded with roses, sheltering the mechanical masterpieces of the 1907 product of the automobile factories, cannot but delight the New Englanders who have been so badly buffeted about by the raw North winds this exceptionally cold and severe Winter. It will be like a jump forward of two months into the springtime atmosphere of early May. But it is not alone in its decorative features that the Boston show claims superiority. Its main claim rests on the fact that here, and only here, in the eastern half of the United States, can the season's progress in automobile construction be observed and studied at one time, in one place and without distinction between exhibitors. Selden licensees of years' standing, and the youngest comer from some local machine shop are aligned side by side and invite comparison. It is the boast of the management that nowhere east of Chicago is there so thoroughly representative an exhibition of motor vehicles as that which has been arranged for the delectation of New England people.

When it comes to the third adjective, "Busier," evidence, in its nature circumstantial, must be relied upon to prove the case, for it will not be until the end of the show, when the exhibitors have had a chance to figure results, that the business will be definitely known. But circumstantial evidence is often stronger than direct, and all that at hand points to the Boston show as a record breaker in point of attendance and sales. Since the 1907 models made their appearance three months ago, the local dealers have been conducting a strenuous campaign, and many are the buyers whose appetites for motoring have been whetted by the accounts of shows in other cities and by demonstrations in Boston, and who have been brought to the point where they just want "to look 'em over" once more before signing the order and making the deposit. There are so many of these that all the previous records of the Boston show for business are likely to go by the board. Another thing that has always made the Boston show noted for its sales, is that the spring riding season is only a few weeks away, and even the most inexperienced know that if they wait any longer the 1908 models will be out before they have a chance to ride in their 1907 cars.

Why the Boston Show Is Held in the Spring.

It has often been said, particularly within the past year, that the Boston show ought to be earlier in the season, and the change has been advocated to some extent. It is claimed that the show now comes in the midst of the selling season and interrupts business for a couple of weeks just when the dealers need their time for giving attention to customers. It is also claimed that being so late it keeps purchasers from placing their orders and makes deliveries late. This argument, of course, has some weight, but the great fact remains that in Boston and at the Boston show the dealers come in contact with the purchasers, instead of the factories with agents. It is in no way an agent's show, though more or less agency work is done. It is a show that is retail rather than wholesale in its character; and, therefore, its closeness to the open riding season is an advantage, for purchasers do not want to put up their money or receive their car any earlier than necessary before they desire to make use of it.

At the opening of the show this year it is planned to have some little ceremony. The Boston management cannot get the diplomatic corps from Washington to grace the affair, and it has not invited the President, but it will have some of the prominent men in the automobile line on hand for the preliminary opening. Nothing elaborate will be attempted, but there will be a select few who will get a glimpse of the apple orchard before the great Saturday night crowd is admitted. This is an innovation, as heretofore the doors have been thrown open to all at the appointed hour and when the thousands got ready to leave the building it required all day Sunday to put it in presentable condition for the real interested parties who make it a point to stay away from the opening night. The real opening will take place at 8 o'clock Saturday evening, but beginning Monday the doors will be open from 10 o'clock in the forenoon until 10 o'clock at night. One ticket will admit to all departments of the show.

STATISTICS THAT TELL OF ITS BIGNESS.

According to Manager Chester I. Campbell, the following statistics illustrate how great will be Boston's fifth show. The Paris Salon figures somewhat spoil the leadership in the accompanying statistics, and so nothing is said of the French affair.

The Number of Exhibitors.

A. C. A. Show, Grand Central Palace, New York, December, 1906	230
A. L. A. M. Show, Madison Square Garden, New York, January, 1907	249
Chicago Show, Coliseum, February, 1907	270
London Show, Olympia, December, 1906	290
Boston Show, March, 1907	342

Individual Makes of Automobiles.

A. C. A. Show, Grand Central Palace, New York, December, 1906	85
A. L. A. M. Show, Madison Square Garden, New York, January, 1907	45
Chicago Show, Coliseum, February, 1907	96
Boston Show, March, 1907	121

Total Number of Cars Exhibited.

A. C. A. Show, Grand Central Palace, New York, December, 1906	251
A. L. A. M. Show, Madison Square Garden, New York, January, 1907	238
Chicago Show, Coliseum, February, 1907	359
Boston Show, March, 1907	423

NEW CARS AT THE BOSTON SHOW.

Though the closing event of the show season held at the Hub has always been productive of novelties in the shape of new entrants into the field of automobile builders, this has seldom, if ever, been the case to the same extent as will mark this year's show. Gasoline, steam and electric cars are all represented. No less than eight of the first-named type will make their debut.

These are the Bay State Forty, Bay State Automobile Company; the Bailey, Bailey Automobile Company; the Aurora, Brown Motor Car Company; the Gearless, two-cycle and four-cycle, Gearless Transmission Company; the Holmes, Holmes Motor Vehicle Company; the Heyman, Edward Heyman; the Mason, Puritan Motor Co.; and the Broubot, K. A. Skinner.

The Clark steamer, built by Edward S. Clark, is the sole new representative to appear in this class, while in the electric field there are the Bailey, S. R. Bailey & Company, Inc.; and the Boston, made by the Concord Motor Car Company.

A SHOW LAUNCH WITH FEATURES.

One of the Maine exhibitors will show in the boat department a launch built expressly for a young woman who has attained a wide reputation as a daring racer of motor boats. The launch is built on very graceful lines, of approved design, and has many noticeable features, one particularly, which the women will admire, is the enclosed engine, as no motor is in sight, and all danger of a woman's skirt becoming entangled in the moving parts of the machinery is eliminated.

WHY THE BOSTON SHOW IS A NECESSITY

WITH the rapid spread of the automobile show idea throughout the country, until every city where there are a few agencies, is clamoring for a show and the agents are asking the manufacturers to help them out by supplying show cars, it is no wonder that the manufacturers are much disturbed at the prospect, and look with favor on the suggestion to limit the number of shows to the so-called national exhibitions in New York and Chicago. Boston representatives who have been called upon by their agents in other New England cities to supply cars and help out at the local shows can sympathize with the manufacturers to a certain extent, for these small shows require very much time and do not yield an adequate return. When it comes to a suggestion that the Boston show be eliminated, the Boston and New England dealers, however, are at once in arms, for they believe that the annual Boston show is as necessary from an industrial standpoint as are the New York and Chicago shows. New England people, they argue, cannot be forced to go to New York to select their cars, especially when, in order to see all the machines, two trips would be necessary. Furthermore, the Boston show has always been a big seller, and as a means of arousing enthusiasm for automobiling and as an agent of publicity is unequaled.

There is, however, among the Boston dealers, a feeling that while it is better to have the Boston show in the late rather than the early Winter, as it is in effect a retail show, business being done between agents and owners, rather than between manufacturers and agents, it might be a good plan to advance the date a few weeks so as to bring the show into February, having it come a little nearer after the Chicago show. The middle of March as a show time is a little too late, for it comes just in the midst of the selling season, and tends to delay orders, and in consequence make deliveries late. The movement for an earlier show has not taken definite form just yet, but there is a possibility that when the Dealers' Association gets ready to make its preliminary plans for the 1908 show, it may decide to have it in February instead of March.

As the Manager of the Shows Looks at It.

Speaking of the place in the industry occupied by the Boston show, Chester I. Campbell, who has managed the Boston show for the past three or four years, said:

"The Boston show is entirely different from the national shows in New York, but has as important bearing on the industry in its way as the earlier exhibitions. The Boston show is not for the purpose of giving the manufacturers a chance to show their agents the new product and to place new agencies, nor is it to give the agents an opportunity to become familiar with the cars for the coming season. On the contrary, our show is to instruct individuals and prospective owners. It is essentially a retail show, so to speak; it comes too late for agency business. The people who have made up their minds just what car they want may buy earlier, but there is always a great host that is undecided, and the Boston show creates enthusiasm among these. We have considered the question of holding the show earlier in the season, and while there is some feeling among the members of the Automobile Dealers' Association in favor of an earlier show, I do not think that the majority would want it much earlier than at present. It might be advisable to move back the date to the middle of February, providing we could secure the halls for that time, but no earlier. Even in February there would be less chance for demonstrations, which are an important part of a show held primarily for those who are going to buy cars for their own use and drive them. The importance of the Boston show from an industrial standpoint is best demonstrated by past results. Sales have always been very large and the attendance remarkable, while in point of space the Boston show is the largest in the country. We have already received sixty applications for

space in the 1908 show and it is not at all improbable that we will have to separate the motor boat show in another year in order that there may be sufficient space for the growing number of automobiles."

According to the Treasurer of the Association.

Harry Fosdick, who has been an automobile dealer in Boston ever since the trade was concentrated in two or three types of steam buggies, and who is now treasurer of the Dealers' Association, is enthusiastic over the advantages of the Boston show.

"The manufacturers may call our show local, but it is as much national in effect as the Chicago show. If the show were omitted the manufacturers would hurt themselves as much as the local dealers, for the New England trade is a large one and important. Boston and New England people do business different from the way it is done in New York. In that city sales are made quickly; here the buyer wants to investigate thoroughly and be sure of what he is getting before he pays his money. He doesn't buy on the spur of the moment and therefore doesn't like to buy in New York. Besides, New England people take an interest in things in Boston and will come here from Maine, Vermont and New Hampshire; Boston sets the style, so to speak. Some Boston people go over to New York, but they go to get ideas, and don't buy there to any extent. Our show might be a little earlier, perhaps, but it occupies a peculiar place in the industry; it is a place where actual business is done and as such does not need to be so early as the shows where the larger part of the sales are by the manufacturers to their agents."

From the President of the Association.

J. H. MacAlman, president of the Dealers' Association, when asked for his opinion concerning the industrial importance of the Boston show, said:

"The anxiety of the manufacturers to secure space in our show and its growth in the past two or three years are proof enough, if any is needed, of the high place the Boston show holds in the estimation of the manufacturers. We are absolutely unable to accommodate all who have applied to us for exhibition space this year. Boston is one of the largest automobile centers in the country and Boston people demand an exhibition where they can see all the cars before deciding which they will buy. The Boston show is a retail exhibition for New England. The New York shows come at a time when all the cars are not ready and the product that is shown is more in the nature of machine shop cars. The cars at the Boston show, on the other hand, are the manufactured product ready for delivery from the floor. The attendance and sales of the past shows indicate clearly that Boston people are ready and willing to support a show and are anxious to see the cars."

The Opinion of the Vice-President.

George H. Lowe, vice-president of the Dealers' Association, has been in the New England trade since the automobile made its first appearance, and he has had more or less to do with Boston show promoting since it began. He commented in this vein:

"To my way of thinking, the Boston show is an absolute necessity to the automobile trade of New England. There are many down Easters who have neither the time nor the money to make the long trip to New York, but they desire to look over all the cars, even though they select a later model of the cars which they might be driving. In point of immediate results, it is pretty safe to say that the Boston show results in the sale of more cars than any other exhibition held in the country. People certainly come to the Boston Show for the purpose of buying, and in the majority of cases the experienced expositors see to it that they do not go away empty-handed. And New Englanders are cautious buyers."

HISTORY OF BOSTON AUTOMOBILE SHOWS

IT is so long since Boston had an unsuccessful automobile show that most of the people who crowd their way into the big Mechanics Building this year will probably have forgotten all about it. Some of them will recall that the big shows previous to last year were given in Symphony Hall, farther up the avenue; but they will remember the Symphony Hall shows merely as good displays that proved tremendously popular with the show-going public and automobile enthusiasts of all sorts.

The fact is, automobile shows in Boston beginning with that of 1903 have been remarkably successful. They have needed no apologies, even on the score of lateness in opening, for the Boston public has shown itself perfectly ready to wait until March for a look at the local offerings, regardless of the fact that new models have usually been seen and discussed pretty generally at the big shows in New York and Chicago, earlier in the year.

One new thing about the show in Boston this year is the organization back of it. Since last year's exhibition a reorganization has been effected, and this year's show is given under the auspices of the Boston Automobile Dealers' Association, Incorporated, instead of the Boston Automobile Dealers' Association.

But to get back to the last unsuccessful show: It was in Mechanics Building, in 1903. It failed of success because of a split between the local automobile clubmen and the dealers. All hands started early in the winter to work together for a show; but when it developed that each faction wanted to be the guiding influence, the parties separated. The clubmen, organizing what was known as the New England Automobile Association, gave a show in the main hall of Mechanics Building in February, at the same time that the New England Kennel Club's dog show occupied Exhibition hall, in the same building. But most of the dealers held back their cars for the dealers' show, which was then planned for Symphony Hall in March; and the result was a meagre display of vehicles at the club show, and the substitution of "stunts" on the broad floor instead of an exhibition of new-model autos.

The show of the dealers, in March, proved doubly successful on account of the fiasco in February; the gate receipts were in excess of the dealers' wildest anticipations, and dealers and public were alike gratified. Another successful show was given in Symphony Hall in 1904; but thereafter more room was imperative, and the dealers moved down to Mechanics Building in 1905, taking the whole building with such success that they have continued there until the present season, with a show each March. Meanwhile, certain dealers had a rival show in Symphony

Hall in show week of 1905, and last year Symphony Hall was used in the show week for an exhibition composed largely of imported cars—virtually an overflow exhibit of cars crowded out of Mechanics Building. Horticultural Hall has been used each year for a power boat show, except last year, when the power boats were in the basement of Mechanics Building.

Early automobile shows in Boston were always in conjunction with some other and larger exhibition. The first was an adjunct to the Mechanics Fair, so-called, or customary exhibition of the Massachusetts Charitable Mechanics Association, in Mechanics Building. It was given in November, 1898, and while the main floors of the building were occupied as usual in the Mechanics Fair by all sorts of machinery, a section of the basement was given especially to automobiles. This section was visited by many persons interested in the automobile as a novelty, but it attracted little popular notice. The Charitable Mechanic Association, however, did much to stimulate interest among inventors of that day by offering \$1,100 in prizes for automobile events given one afternoon during show week at the Charles River Bicycle Park, near the Cambridge end of the Harvard Bridge.

Subsequent automobile shows in Boston were merely small displays in connection with industrial shows or food fairs until 1901. In that year a company of professional show promoters came to town prepared to run a big automobile exhibition and reap a harvest. They engaged Mechanics Hall; but they charged such amounts for floor space that comparatively few manufacturers or dealers cared to bid for popular favor through their show, and as a result the exhibition was a fizzle. The public did not attend in large numbers and those who went saw comparatively few machines.

Partly to overcome the ill effect of this show on the public mind, the dealers and the members of the newly-formed automobile club in 1902 joined with the promoters of a big fair that was to be held in Mechanics Building, and arranged for an automobile section. All hands, dealers, clubmen and users of commercial vehicles, joined to make this exhibit a good one; and for a small show it was a pretty good success. One of its interesting features was a street parade, starting from the Mechanics Building and touring the business and financial districts in mid-forenoon. The 1902 show was the first to convince the public that steam, gasoline and electric cars were all being developed successfully; and it paved the way to the enlarged public interest that has been in evidence at all shows since that year.

BOSTON'S 1906 SHOW OPENED WITH IDEAL WEATHER.

LATER A SNOWSTORM MADE DEMONSTRATIONS DIFFICULT.

TO TAX AUTOISTS FOR ROADS BUILDING?

NEW HAVEN, CONN., March 3.—A bill for the bonding of the State for a large sum for the building of a comprehensive system of highways is now before the Connecticut legislative committee on roads, bridges and rivers.

Representative Charles G. Allerton, of Middlebury, Conn., house chairman of the committee on roads, bridges and rivers, is in favor of a bill taxing all automobiles in the State.

"The bonding of the State, say for \$5,000,000, to meet the expense of building an efficient system of highways would entail practically no burden on the people of the State and the result would be of inestimable benefit to rural communities.

"There is now, I learn, 400,000 horsepower in automobiles in use in this State. If a tax of say 50 cents a horsepower were levied on the owners, \$200,000 a year could be raised which would pay the interest on \$5,000,000 worth of bonds.

Mr. Allerton, being a successful farmer in Middlebury, thoroughly appreciates the value in facilitating the marketing of farm products by good highways.

GOVERNMENT DOING LITTLE FOR ROADS.

WASHINGTON, D. C., March 2.—Logan W. Page, director of the Office of Public Roads, recently appeared before the Committee on Expenditures in the Agricultural Department and gave the members considerable information about the work being done by his bureau.

Director Page informed the committee that he and his staff must get means for meeting this problem, and they are making experiments with every known material that they thought will accomplish the desired end.

STATUS OF THE AUTOMOBILE IN NEW ENGLAND

By C. F. MARDEN.

NEW ENGLAND is recognized by automobilists everywhere as one of the best touring districts in the country; if any proof were necessary it could be found in the fact that the last two contests for the Glidden trophy, the great national touring event, have entered New England. The district has better roads than can be found in any other six States in the Union; it is better equipped with hotel facilities, and automobilists are treated better than in most other places. In addition to this are its great natural advantages. It is difficult to find a more pleasant destination for a tour than the White Mountains, which have come to be very popular with automobile owners in the past two or three years, due partly, perhaps, to the hospitality of the hotelkeepers and their efforts to make things interesting.

It is no wonder, then, that automobiling in New England has made such giant strides forward. It is conservatively estimated that there are registered in the six States in New England nearly 30,000 cars. If this is a correct estimate, then New England has nearly 20 per cent. of all the cars registered in the States which have registration laws. According to the latest statistics available, there were 26,377 automobiles registered in the New England States. Massachusetts was in the lead with 17,299, Connecticut second with 3,900, Rhode Island third with 1,714, Maine fourth with 1,364, New Hampshire fifth with 1,253, and Vermont last with 847. These figures were made up some time ago, so that it is likely that a total of 30,000 cars in the six States is nearer correct at the present time.

In the organization of automobilists also New England is well to the fore, and few States can boast as many clubs as there are in these States. Massachusetts alone has not less than half a dozen well organized clubs. Among these are the Massachusetts Automobile Club, Bay State Automobile Association, North Shore Automobile Club, Worcester Automobile Club, Fitchburg Automobile Club, Springfield Automobile Club, and others of lesser importance. Maine has a club at Portland, New Hampshire a flourishing organization at Manchester, Rhode Island the Rhode Island Automobile Club, and Connecticut several organizations in the larger cities.

Though there seems to be a tendency to swing the national

competitive events away from New England in 1907 to satisfy the clamoring of the growing West, New England has always been prominent in these affairs, being represented by several citizens in touring contests ever since the famous Pittsburg mud run. New Englanders were prominent in the first Glidden tour from New York to the White Mountains and return, and in the tour last summer from Buffalo to the same destination.

In racing, too, New England has set the style. One of the first race meetings in the country was that at Newport, when William K. Vanderbilt, Jr.'s *Red Devil*, John Jacob Astor's steamer, Kenneth Skinner's motor tricycle and an electric car were the contestants in the free-for-all that was the final event on the programme of the races on the half-mile Aquidneck Park dirt track. Few more successful track meetings have been held anywhere than those at the Peadville track, near Boston.

It is as a manufacturing center alone that New England has to give place to other sections of the country. Less favored by proximity to the sources of supply, by labor and by transportation conditions, than some of the States of the Central West, the manufacturing of automobiles has not grown as fast here as in other places. Yet some of the best known cars in America come from the six States in the northeast corner of the United States. Such cars as the Columbia, the Pope-Hartford, the Locomobile, the Knox, the Stevens-Duryea and the Napier are manufactured in New England, and in a summary of production the output of these factories would give New England a not inconspicuous place in the industry.

As a selling community New England is one of the best, standing second only to New York, and its possibilities have as yet not been fully developed. Boston has been exploited to a considerable extent and probably has more automobiles per capita than most of the larger cities, but there is a large territory in Maine, New Hampshire and Vermont that is only now being opened up. Boston dealers are reaching out into these States, establishing agencies and preparing for a campaign which, during the next year, is likely to largely increase the number of cars in use in these States. The future of the industry has no more promising field than the above territory.

INDICATIONS OF EARLY SPRING IN NEW ENGLAND.—A CORBIN UPON A MODEL CONNECTICUT HIGHWAY.

THE FLOURISHING AUTOMOBILE CLUBS OF BOSTON

CLUB life of Boston automobilists has had two periods of almost kaleidoscopic change. The earliest was in the days when the possibility of getting motorists enough together to carry on a respectable organization first made itself evident. The second was within the last three years after the big local shows had stimulated enthusiasm.

The club idea first spread to Boston in 1900. It came as a unit, but it found two factions of automobile enthusiasts waiting to appropriate it. One wanted to turn it to the building of a comfortable clubhouse in the country; the other saw no sense in any kind of a club unless it established an "automobile stable," as they called it in those days, in the midst of the city. The first aggregation developed into the old New England Automobile Club; the other organized the old Massachusetts Automobile Club.

They were rivals in about everything, at the start. The New England got in first with its organization—October 8, 1900—but was not incorporated until January 11 following; whereas the Massachusetts had the foresight to organize as a corporation at the start, thus antedating the other on the official records with a charter dated October 31, 1900. The Massachusetts had J. Ransom Bridge for president, Conrad J. Ructer for treasurer, and L. E. Knott for secretary. The New England's leaders were Arthur W. Stedman as president, Francis R. Hart as vice-president, George McQuesten as secretary, and Royal R. Sheldon as treasurer. The Massachusetts had on its original Board of Governors, Capt. Homer W. Hedge, John Brisben Walker, Jr., Ernest Rueter, Dr. W. A. Rolfe, and others; while the New England's executive committee included such enthusiasts as F. E. Stanley, Knight Neftel, Henry Howard and C. L. Edgar.

Both organizations were keen after a clubhouse, but the New England, composed very largely of members of the Country Club of Brookline, managed very soon to get control of the house and grounds of old Suburban Club, a driving club, in the heart of Brookline just across the road from the Country Club park; and with a housewarming here on February 22, 1901, the New England inaugurated a brief but active career. Its activity was largely confined to the ensuing season, when it had the distinction of running the first automobile race meet ever attempted east of New York, and on June 16, the day after this meet, had the first big club run, which was from Brookline to Marblehead and return. The race meet took place on the Country Club half-mile oval track.

The Massachusetts club had the biggest club run ever held in this State, so far as mere stringing out of vehicles is concerned, on June 17, when the club got together automobiles and their owners from all parts of the district and ran from Boston to Sharon. What a string of sixty or seventy autos can do in the way of raising a dust on a hot June day was shown so conclusively at that time that nobody in Boston has ever attempted that kind of a club run since.

The Massachusetts Automobile Club.

Events of that summer, however, showed that while the two clubs might own to slightly different ideals, their objects were in fact about the same; and in the fall they got together, buried the hatchet, and formed a new organization under the name of the Massachusetts Automobile Club, with Col. James T. Soutter as president, Elliot C. Lee as vice-president, Dr. J. C. Stedman as second vice-president, Royal R. Sheldon as treasurer, Dr. F. L. D. Rust as secretary, and A. W. Stedman, C. J. Glidden, George McQuesten, Henry Howard, J. R. Bridge, Newton Crane, Dr. W. A. Rolfe and Ernest Reuter as directors. Plans for a city clubhouse were at once drawn up; the building was pushed to completion; and on the evening of January 1, 1902, there was a splendid housewarming. This clubhouse is on Boylston street, with garage on the first floor and basement; club parlors, billiard

rooms, and dining-rooms on the second floor; and repair rooms on the third floor. As a convenient place for storing cars the club has always been prosperous, and this feature of its activity increased so rapidly after the first year that in 1904 the three-story brick building on Boylston street was enlarged to three times its original size, and provisions made for caring for a largely increased number of automobiles.

Flourishing Life of the Bay Staters.

The Bay State Automobile Association came into being in January, 1905, with the idea of benefitting all users of motor vehicles with merely nominal expense to individual members. The social features of automobile ownership were to be kept well to the fore, yet it was also intended to foster the good roads movement, to give conservative protection against drastic legislation, and to work for rational rules and regulations governing the use of all classes of cars.

The first headquarters were a pleasant and convenient suite of rooms on the ground floor of the Hotel Lenox, about a minute's walk toward Copley square from the house of the Massachusetts Automobile Club. But as the season developed, the club members began to interest themselves in club runs and racing plans; they became eager for a house in the country. They had successful race meets at Readville that first year, with club runs to Rye Beach and other places. On December 1 the association took possession of what was known as the Annex of the old Woodland Park Hotel, at Auburndale; and in those quarters they enjoyed all the comforts of a well-equipped clubhouse, with the hotel to supply the dining room. Many meetings, dinners and smokers were enjoyed there; and the annual meeting was turned into a New Year's party, celebrating the conclusion of a very successful year. The association had at that time 394 members and a cash balance of about \$3,000.

From these quarters the association was obliged to retire by reason of a fire that destroyed the building; but on May 1, 1906, the organization decided to take a five-year lease of the five-story brick dwelling, 283 Dartmouth street, in Boston, with the idea of making this the permanent club home. Almost next door to the Hotel Vendome, within a few steps of Commonwealth avenue on one side and Copley square on the other, and with a broad stretch of unbroken asphalt to form the street surface in front, this house was at once recognized as particularly well located; and for two months all sorts of workmen were employed, remodeling and refitting and refurnishing the commodious interior. On July 12 the house was informally dedicated, with speeches by President L. R. Speare, who received the keys from Secretary James Fortescue, and by Vice-President H. W. Whipple, President P. J. Coghlin, of the Worcester Automobile Club, and others. The association entered its new building with a membership of 600.

The association has held a number of race meets and hill climbs, all successful, and last November tried its hand at gymkhana sports.

The officers at present are as follows: President, Lewis R. Speare; vice-president, Harlan W. Whipple; secretary, James Fortescue; treasurer, Harry Knights; directors, Charles E. Fay, Arthur Hinchcliffe, Arthur P. Underhill, John C. Kerrison and George W. McNear. Mr. Speare has been president since the association was first organized, and has proved a popular and efficient officer.

Other organizations which have played their somewhat more utilitarian part in the automobile activities of Massachusetts in the past two years are the Massachusetts State Automobile Association, an A. A. A. organization composed of all the leading clubs; the Automobile Owners' Association, largely for protective purposes; and the Boston Automobile Dealers' Association, which has continued to look after the interests of the trade.

MOTOR BOATING IN NEW ENGLAND WATERS

SCRATCH the skin of a New Englander and you disclose a man who loves the sea. On no section of our country's coastline is there such a marked development of the sailor instinct as is inherently engrafted in the citizen of the New England States, notably those of Massachusetts and Maine. In any foreign port one is sure to find the Yankee salt aboard some vessel in the harbor, and usually in some position of command, a significant truism.

Nature's prodigal hand has lavishly bestowed on New England's picturesque coastline a magnificent series of deep indentations—bays and admirably sheltered harbors, the equal of which would be hard to duplicate in any other 2,000 miles of rocky shore. Every favoring condition has fostered the aquatic temperament and it needed but the advent of the motor boat to crystallize this phase of character into a ruling passion.

From the Connecticut State boundary on Long Island Sound to the farthest coast limit of Maine at Eastport, thousands of motor-driven craft, embodying every type from the humble dory of the industrious fisherman to the palatial cabined yacht of the Boston copper kings. So great has been the demand during the last half dozen years that builders have been driven to their wits' end to fill orders.

The head and center of the market for motor boats in New England is, of course, Boston and its environs, with its unequalled harbor and that splendid expanse of sea water, Massachusetts Bay, whose northerly extremity is Cape Ann, and whose southern end is tipped by Cape Cod. Within this charmed circle is the beautiful harbor of Marblehead, the famous mecca of all motor boatists and yachtsmen in summer. Just now, interest in motor boat circles is centered in the big race for this type of craft, of 270 miles, from New Rochelle, N. Y., to Marblehead, Mass., which will start on July 20, for the Stevens cup. This race is for cruising power boats between 30 and 40 feet over all, and these will be rated on a modified rule, and time allowance will be figured at 60 per cent. of the regular allowances. The boats will be allowed to make one stop for supplies at Cottage City.

In and about Boston, the motor boat has reached its highest development as a commercial conveyance, due largely to the great fishing industries of the coast, of which the Hub is a center. Prior to the advent of the gasoline marine motor, these industrious sea merchants plied their dangerous vocation with sail power. To-day the sail is but an auxiliary, and there is scarcely a vessel in the fishing fleet that is not supplied with a gasoline engine.

New England's inland lakes also offer a fruitful field for the pleasures of motor boating. Thousands of these lakes dot the map, especially in the States of Maine, New Hampshire and Vermont, and all of them teem in summer with power boats, big and little. They are now considered a part of the regular equipment of the summer resident, and the delightful climate is yearly increasing the number of these summer visitors in the inland mountain districts as well as at the shore resorts.

The industry of boat building, always an important one in this part of the Atlantic Coast, has vastly increased under the impetus given by the application of the motor as a power factor, and bids fair to assume proportions that will astonish statisticians within the next ten years.

THE NATIONAL CHAUFFEURS' CLUB.

The National Professional Chauffeurs' Club has its Eastern headquarters at 1947 Broadway, New York City. Its officers are as follows: President, Alden Markham; vice-president, Wm. C. Hurst; treasurer, E. Nassoy; financial secretary, Bertrand Hope; recording secretary, Philip A. Hagel. A recent announcement by the club contains the following:

"This club is organized to encourage the education of its members, and to bring to those members that high standard of efficiency that employers will recognize the advantage of employing members of the National Professional Chauffeurs' Club who have passed an examination necessary to obtain a certificate of membership in this club."

"MAXINE," J. H. MCCARTHY, BOSTON, OWNER AND CAPTAIN; WINNER OF MOTOR BOAT RACE HALIFAX RIVER, FLORIDA, FEB. 22.

MINNEAPOLIS HAVING ITS BIG SHOW.

MINNEAPOLIS, MINN., March 4.—The first annual Minneapolis automobile show opened Saturday afternoon under the most satisfactory conditions. The new National Guard Armory is crowded with cars and the balcony spaces are packed to their utmost with accessory exhibits and special exhibits of various kinds. The show is drawing crowds from all parts of the Northwest, as it is the first exhibition of the kind given west of Chicago.

The formal opening occurred at 8 o'clock, when Governor Johnson and Mayor Haynes of Minneapolis delivered short addresses. Nearly 100 cars are in place on the floor of the Armory. The big drill hall is magnificently decorated, the general effect being the most satisfactory that has characterized any show ever given in the Middle West. The costly decorations of the Chicago show were transported to Minneapolis almost in their entirety and are displayed to better advantage in the Minneapolis Armory than they were in the Chicago Coliseum. The general scheme of the decorations is in purple and gold. A sky of bunting overhangs the entire hall, and thousands of lights make the scene a most brilliant one at night. The heavy plaster friezes, pillars and other parts of the decorations brought from Chicago have been used with wonderfully good effect.

NATIONAL GUARD ARMORY WHICH HOUSES THE SHOW.

All of the exhibitors of cars are retailers, with the exception of the H. E. Wilcox Motor Car Company of Minneapolis, which shows for the first time the Wolfe car, built by the company.

There are a number of novelties displayed. Electric power has been used to drive the exhibition chassis and stripped models of the demonstration cars on the floor of the Armory. The exhibitors are as follows:

Main Floor.—Pence Automobile Co., Jordan Auto Co., Northwestern Cadillac Co., Haynes Automobile Co., Fawkes Auto Co., Northwestern Automobile Co., F. G. Winston, Jr., Columbus Buggy Co., G. W. Caplin, Walter G. Benz, A. C. Bennett, Evans Motor Car Co., Aerocar Co., Barclay Automobile Co., H. E. Wilcox Motor Car Co., W. C. Thornhill, Wallis Coach & Carriage Co., East Side Auto Co., Maxfield & Rice Bros., A. F. Chase & Co., Auto Selling & Repair Company.

Balcony Exhibitors.—C. J. Smith, St. Paul; Invincible Tire & Armor Co., Hartly, Iowa; Louglin & Brugger, Fon du Lac, Wis.; V. Houbert, St. Louis; Bailey Leather Tire Co., Milwaukee; Tokheim Mfg. Co., Cedar Rapids, Iowa; Gugler Electric Co., O. Fenstermacher & Co., Hoills Electric Co., Frederick Roach, Penn Oil & Supply Co., J. N. Johnson Co., Beckley Ralston, Shadegg Engine Co., Minneapolis Electric Motor Co., Sorg-Bader Co., E. J. Hodgson, Fawkes Automobile Co., Index Speedometer, Evans Motor Car Co., Western Auto Co., General Electric Co., Twin City Motor Co.

GITHENS WILL NOT LEAVE THE G & J TIRE CO.

DETROIT, MICH., March 4.—H. A. Githens, long identified with the G & J Tire Company, positively denies the report that he intends resigning his present position to become identified with the Empire Automobile Tire Company.

CHICAGO TRADE ELECTS GUNTHER.

CHICAGO, March 4.—At the annual meeting of the Chicago Automobile Trade Association Joseph F. Gunther, manager of the Chicago branch of Thomas B. Jeffery & Company, was unanimously elected president. It was expected that there would be an opposition ticket in the field, but the movement collapsed owing to the refusal of Orlando F. Weber, agent for the Pope cars, to head it. Thomas Hay, manager of the Chicago branch of the Ford Motor Company, had been nominated as secretary, but declined owing to press of other matters, and Fred Dayton, manager of the local branch of the Electric Vehicle Company, accepted the office. Henry Paulman, Chicago agent for the Pierce, was elected vice-president, and Walter Githens, who held the latter office during the past year, was selected for the post of treasurer, the election of all the officers being by acclamation. Ralph Temple, the retiring president, was elected a director, with Orlando F. Weber and F. W. Cornish as his associates on the board. Mr. Gunther, who officiated as treasurer last year, was one of the original founders of the organization. The matter of contests was the only other business considered, and it is proposed to repeat all those held last year.

A resolution was adopted requesting the A. A. A. Touring Board to end the tour in Chicago.

A petition was also prepared and presented to S. A. Miles, urging that an earlier date be named for the holding of the Chicago show.

PORTLAND, ME., HAS SUCCESSFUL SHOW.

PORTLAND, ME., March 2.—With band playing, thousands of electric lights blazing, and a big throng leaving the building, the second annual automobile and power boat show in Portland came to a triumphant conclusion this evening. For one solid week the exhibition had held sway in Portland's biggest show building and during that time, forenoon, afternoon and evening, crowds had filled the building. One year ago Frederick M. Prescott of Boston gave the first Portland show. While it was in a measure successful, the financial end did not come up to expectations. Mr. Prescott was not disheartened, however, and immediately re-engaged the Auditorium for 1907, and has now secured it for 1908. Mr. Prescott announced at the end of last week's show the complete success of the venture from every standpoint.

Although the streets of Portland were piled high with snow during the show week, this did not deter the various exhibitors from demonstrating their cars, and many a machine received a very trying try-out. The weather itself was favorable for the exhibition and hundreds of people came from all over the State to attend the show.

RAMBLER'S NON-STOP RUN OVER 2,000 MILES.

MILWAUKEE, March 1.—After running 2,002 miles in 140 hours and 36 minutes, Van Evra B. Martin's three-year-old Rambler brought its non-stop run to an end in this city through the clogging of a gasoline pipe. The run was started upon by the owner of the car, an enthusiastic autoist who had taken exception to an article in a Milwaukee paper saying that stock cars were not equal to the non-stop runs performed by various manufacturers. Van Evra B. Martin's intention was to run one thousand miles without stopping the motor, but he more than doubled this distance and might have gone still further if the run had been confined to Milwaukee boulevards. The run was started with no other preparation than new tires and batteries. Mr. Martin drove the machine himself for most of the distance.

PREMIER TO BUILD A WATER-COOLED "SIX."

INDIANAPOLIS, IND., March 4.—The Premier Motor Manufacturing Company will bring out a six-cylinder water-cooled car next season. Factory experts are now at work on the design, and a trial car will be ready, it is expected, within a few months. It is understood that the Nordyke & Marmon Company will bring out a six-cylinder air-cooled car next season.

KELSEY'S TAXIMETER CAB PLANS.

C. W. Kelsey, who has now definitely announced the organization of a large company for the building and operating of taximeter cabs and delivery wagons in the larger Eastern cities, of which he is to be general manager, is now in New York City completing the details of the organization. Mr. Kelsey said recently in discussing the cab situation:

"We shall be ready in a very few weeks to announce to the public the details of the methods by means of which we shall be able to give to New York, Philadelphia, and Boston (and later to other cities) the most complete and reasonable-priced cab service they have ever had. The cabs will be put in service as fast as they can be built, the style of design and construction having been already decided upon. The cabs will be driven by chauffeurs who will handle them upon a percentage, and the method in use abroad of using an indicator showing that they are available for hiring, will be installed in this country. A flag, which will be tipped down when the cab is in use, will be displayed as soon as the call is at an end and the cabs will be ready for service whenever and wherever they are seen with the flag flying. The mechanical device known in Europe as a taximeter will show the occupant just how far he has traveled and what he will have to pay for the service. The prices will be far lower than those now in vogue, even for horse-drawn cabs, and, of course, the service will be far more satisfactory.

"In addition, the company will build delivery wagons and trucks which will be leased to merchants and business houses of all descriptions by the year, and will be kept in repair by the owning company. This will take from the merchant the bother of establishing garages and repair shops, and as the drivers are to be furnished with the wagons, there will not be the trouble heretofore encountered in securing reliable help. To provide for this business, the new company will establish large shops in the cities mentioned, and extensive schools similar to those run by the street car companies for the training of drivers. There will be also a system of inspection and repairs, by which every vehicle will be thoroughly overhauled at short intervals."

PHILADELPHIA'S PUBLIC AUTO LINES.

PHILADELPHIA, March 4.—On Thursday last the Highway Committee of City Councils negatively recommended the ordinance introduced in the interest of the People's Vehicle Company, asking for a 25-year franchise to operate automobile omnibuses over many of the principal streets in the city, the knock-out being based upon City Solicitor Kinsey's opinion that councils could not constitutionally sign away the sole right to the use of the city's streets for such a purpose. Such a right, he intimated, lay only with the State Legislature.

At the same time the committee favorably recommended the Abrams bill, introduced last December, and giving any transportation company the right to use any or all the streets of the city for operating public autobus lines, and providing for the payment of licenses for such vehicles graded according to the number of passengers carried (up to 30), setting forth the minimum width of tire allowable for vehicles of various weights up to 20,000 pounds. This ordinance had been introduced in the interest of the Auto Transit Company, of Philadelphia, which claims to be able to put a score of buses on Broad and Diamond streets within a month or six weeks after Councils finally pass the measure and the Mayor's signature makes it a law.

The vehicles which the Auto Transit people propose to put on the initial route from City Hall to Fairmount Park via Diamond street, are of the Imperial type, built by the Commercial Truck Company of America, and will be of the four-motor, four-wheel drive design. Although no definite announcement has as yet been made as to the rate of fare to be charged, it is asserted that the Auto Transit Company believes that it can make a profit on the "five-cent, no-seat-no-fare" basis. With a maximum seating capacity of 30, this would seem to be a doubtful proposition.

AN ORIGINAL AUTOMOBILE BODY.

It is a curious fact that after hundreds of years of development the seating accommodation of a horse-drawn vehicle should show practically no progress. The royal coaches of Louis XIV., for instance, are equal in comfort, for a given area, to anything our modern carriage builder produces. When the first automobiles came the driver and his guests sat on a plain wooden seat in a box-like body. Ten years brought greater changes than ten centuries had been able to produce under the horse period, and the automobile body of to-day is the most commodious, comfortable and luxuriously-fitted of any road vehicle that has ever been brought forth.

The countries of the old world have paid most attention to the luxurious type of closed automobile, but that America can produce work equal to the best of the most famous French carrossier is proved by the handsome body built by C. P. Kimball & Co., of Chicago, now on view at the American Locomotive Company showrooms on Broadway and illustrated herewith. The coachwork is mounted on a 22-horsepower Berliet chassis, and forms a happy combination of the best French mechanical skill and the highest American art in bodymaking. The feature of the vehicle is that it is a modernized type of an old English coach, and has all the charm of that old-time vehicle without any of its

OLD ENGLISH COACH BODY, DESIGNED BY KIMBALL.

inconveniences. The body is painted a pale yellow with black lining and black underbody. At the rear is a projection forming a pocket in which swords and pistols were carried in the good old days. Two rear lamps outside and close to the roof add further to the old-time appearance of the vehicle. The side windows are provided with wooden panels sliding into pockets—another old-time idea. All the exterior fittings of the car have a gunmetal finish; the door handle and grip is handsomely carved and really a fine piece of work. Gray broadcloth is the material used for interior upholstery, but is only applied to the seats, floor and lower part of the body, the roof and upper portion of the sides being in polished mahogany. There is one rear seat with seating room for three and two folding seats facing towards the rear. The two outside rear lamps light the interior, but additional illumination is supplied by a couple of electric lamps. A speaking tube communicates with the driver and numerous pockets are supplied for maps, books, etc. Head and side lamps are acetylene, the rear lamps burning kerosene. Wheelbase is 112 inches, track, 55 inches.

UNABLE TO SECURE SKILLED WORKMMEN.

OMAHA, Neb., March 4.—Scarcity of skilled labor has compelled the Karbach Automobile & Vehicle Company to discontinue the manufacture of motor trucks for a year. Advertisements for skilled automobile workers, placed in Eastern papers, failed of successful responses.

AN AEROPLANE BY NOTED INVENTOR.

PARIS, March 1.—An important flying machine of the heavier than air type is expected to make its first appearance before the public in a few days. The aeroplane, which is under construction at the Voisin Frères factory at Billancourt, near Paris, is in general appearance similar to the latest Santos Dumont models. It consists of a cellular frame, presenting an area of about 45 square meters, and weighs altogether 400 pounds. The motor is an eight-cylinder, 24-horsepower air-cooled Buchet, with cylinders forming V, carried at the forward end of a wooden frame very similar to the frame of an automobile, and driving a two-bladed fan. The aeroplane is the property of M. Kapferer, a well-known Paris engineer, who was the first to place on the market

the dismantlable rims which played such an important part in the Grand Prix and other European races last year.

Santos Dumont has removed. On the polo ground at Bagatelle, in the Bois de Boulogne, he was cramped for room and was, in addition, always afraid of coming down on the heads of the numerous sight-seers who gathered to watch his attempts at flying. He therefore this week took up his quarters at Saint-Cyr, to the west of Versailles, where a big shed has been built for him on a large open plain used by the cadets of the military school. The

M. VOISIN.
Head of the well-known
French aeroplane
works.

shed is a commodious structure, with big glass windows, allowing the aeroplane to be taken in and out without any difficulty. No. 14bis, the first machine heavier than the air with which the young Brazilian accomplished a successful flight, is being replaced by a larger model, measuring 40 feet from tip to tip, but only 2 feet in width. The framework is of mahogany, covered with varnished cotton. Between the two wings will be installed a 50-horsepower Antoinette motor of very light weight, specially designed for flying machines. Later this will be replaced by a 100-horsepower motor of the same make. The pilot will be placed above the motor, with the controlling levers in front and the rudder and propeller astern. Santos Dumont has obtained such a satisfactory equilibrium that he has decided to run his flyer over the ground on one wheel only. All previous machines have been started on two wheels. It is expected that the machine will be sufficiently advanced to compete for one of the most important prizes of the Aero Club of France before the winter is over.

EIGHT-CYLINDER BUCHET MOTOR FOR KAPFERER AEROPLANE.

SUCCESSFUL AEROPLANE FLIGHT IN PARIS.

A cable from Paris to the *Herald* announces that M. Vuia has succeeded in flying in a distance of about fifteen yards at a height of four feet and at a speed of about thirty miles an hour. The experiments were made on the Bagatelle polo ground, close to the Bois de Boulogne, Paris, where most of Santos Dumont's flights were made. The Vuia aeroplane has not been so successful as the young Brazilian's machines, but her owner is hopeful of better performances when minor improvements are made.

OLDS "MUDLARK" TO HAVE A HOME COMING.

AKRON, March 4.—The *Mudlark*, the Oldsmobile in which Andrew Auble and Fred. W. Work, of Akron, and R. R. Owen, of Cleveland, rode through sand and mud and water from New York to Florida, has been in this city all this week. It is still equipped with the accoutrements that were used to pull the machine through mud and sand in the Southern States. The machine still carries two of the original Goodrich tires that were on it when it left New York.

Messrs. Auble and Work brought the machine from Cleveland to Akron under adverse conditions in 1 hour 40 minutes. The distance is thirty-five miles. The machine will be driven to Lansing, Mich., where it first saw shape.

M. KAPFERER'S NEW AEROPLANE UNDER CONSTRUCTION IN THE VOISIN FRERES FACTORY NEAR PARIS.

A RUN ROUND THE GRAND PRIX COURSE

PARIS, Feb. 26.—A temporary spell of fine weather had improved the roads somewhat, though the routes in the immediate neighborhood of Paris were far from being inviting, when an invitation came along for a run round the Dieppe circuit. Out through the Porte Maillot, a few miles' bumping over rough *pavé*, and the typical national highways were struck and allowed of good running for the time of the year. The circuit was entered at Londinières, the point nearest to Paris, and a run made up the easterly leg to Eu. These are not the routes nationales, or first-class roads of France, supported by the government, but departmental roads, maintained by the department. Nevertheless they are excellent routes, and permit of the fastest

whose body appeared to have developed in undue proportion to his legs; another carried a couple of milk cans, and was accompanied by a sturdy youngster who ran along by the side of his team, stopping an instant to give a passing cheer to the auto. There is rather a sharp turn under the Dieppe railroad near Eu, and a little further the village itself is struck and the coast leg of the circuit started on. Although the turn is in the heart of the village there is so much space that the racers will not be at all hampered. Eu to Dieppe is a splendid run, winding and hilly at first, later straight and wide, with a view of the English Channel from time to time on the right. But for the photographer in the rear we might have imagined we were practicing for the

A FINE STRETCH OF NORMAN ROAD ON WHICH THE FORTY-THREE WILL SHOW LIGHTNING SPEED.

going. Despite the wintry season the country has a certain charm, with its old orchards, stocked with spreading apple trees which in less than three months will be a picturesque mass of white and colored blossom, its healthy-looking cattle and pleasant meadows. There are a few sharp grades, turns that call for a little skill at high speed, but which are in no way dangerous, and some long straight stretches, with the ribbon of hard gray road stretching out for a couple of miles ahead, tempting the driver to let his four-year-old Renault out to its utmost power until pulled up by the exasperating photographer in the rear of the tonneau with the remark, "I must have a snap at that."

A curious sight was supplied by the primitive little carts pulled by a team of dogs. The auto was stopped as we approached one of these equipages, and the fair Normande sitting in the vehicle asked to pose, which she did without any demur, and with as much natural grace as a Parisian. The dog carts are quite a feature of this part of France, and several were passed while running round the course. One carried a patriarchal individual

race. These roads are never muddy, thanks to their hard surface and the fresh breezes always blowing in from the sea. Dieppe is not touched, the sharp fork-like turn being nearly two miles from the herring town. The turn resembles that of La Fourche on last year's Sarthe circuit, but is much more easily negotiated. Down the third leg of the course from Dieppe to Londinières we fall in with the local railway, which claims a share of the highway. It is not an important affair; the express makes a poor speed showing compared with even our ancient model, all service will be stopped on the day of the race, for the Grand Prix is a fête day, but it is none the less an inconvenient neighbor. For some distance it narrows the road considerably with its high bank. To get more width some of the trees on the inner side will have to be cut down. What is the cost of a few trees? Has not the district offered one hundred thousand francs to the Automobile Club of France? One hundred thousand francs, it is the subject of conversation in every café, and there is not a laborer in the country who has not calculated how long it would

A FEMALE PEDLER AND HER FIVE-DOG TEAM.

RUNNING INTO THE PEACEFUL VILLAGE OF EU.

take him to earn that amount at three francs a day. Envermeu is one of the more important villages on the course, which can be passed through without any difficulty, despite its scattered elongated formation. Its center of attraction now is a village shop, where wax candles, groceries and gasoline can be bought "half wholesale" or retail, a village inn, and an ancient church. The last named will be indifferent to the auto race, but the two for-

mer have an eye open to business and a high ideal of the glorious days which are coming. There are no signs of work on the course yet, but plenty of preparations. The landlord of any of the inns on the forty-seven miles of circuit will tell you all about it, and give the names of every member of the racing board, the list of competitors, their past performances and their full pedigree if you desire it.

IMPORTANT GRAND PRIX PREPARATIONS

PARIS, Feb. 24.—One of the most difficult points to be regulated in connection with the Grand Prix, is the placing of the replenishing stations. Supposing no further entries are received, there will be forty-three competitors, thirty-four of which must be supplied with gasoline at the rate of 6.6 gallons per 62.1 miles, and nine with half this amount. Last year a station was given for each firm, the cars stopping before their familiar sign to take in gasoline, change tires or affect repairs. As the racers will have to take their gasoline in two, or perhaps three doses, it being impossible to carry the full amount from the start, it has been suggested to give a separate station for each machine. Different firms will have from one to five cars in the race, and it is quite possible in the excitement attending the arrival of a machine to hand over the gasoline tank for number 10 to number 20, and probably put the whole race in danger. All machines are

being built to work as near to their fuel limit as possible, and none of them could afford to get the tank of a rival with even a slightly less quantity to his credit. Nor must the unclaimed fuel supply of a broken-down racer be available for surreptitiously feeding its more fortunate companions. The regulations stipulate that the reservoir of each machine shall be filled at the commencement of the race, and the surplus gasoline placed in a sealed vessel and placed at the driver's disposition. Forty-two stations would make an exceedingly long line, and place some of the machines out of the range of vision of the grand stand, a serious defect, for the work at the stations forms one of the most interesting parts of the race. For this reason many of the members of the racing board are in favor of one station per firm, with distinctly marked gasoline cans for each machine, and a very severe control to prevent the possibility of fraud.

THE LOCAL RAILROAD CONSIDERABLY NARROWS THE ROAD.

ENVERMEU IS A TYPICAL NORMAN VILLAGE.

TIME FOR AUTOISTS TO WORK OPENLY FOR ROADS

By JAMES W. ABBOTT, Ex U. S. COMMISSIONER OFFICE PUBLIC ROAD INQUIRIES.

LOS ANGELES, Cal., March 1.—The work for good roads which has been done of recent years in California has lately reached the stage of an impatiently insistent demand that relief be afforded "right away off." A very prominent man of affairs in Los Angeles said to me the other day: "I haven't had my automobile out of the barn in two months; the roads are impassable and I couldn't get anywhere with it." Recently I had occasion to go from Los Angeles on the electric car to Pasadena. As we sailed along thirty miles an hour we came upon a very suggestive spectacle: sunk in a sea of mud was a fine automobile. Attached to its front axle was a long block and tackle contrivance which led to a distant snubbing post. Stretched along either shore of this bayou were enough people for a good-sized village, and a system of foot tracks in the mud was calculated to inspire belief that a futile effort had been made by these sympathetic human beings to extricate the vehicle.

the moribund National Good Roads Association became practically extinct. June 30 of the same year the "Office of Public Road Inquiries" expired by operation of law and its methods of educating public sentiment came to an abrupt termination. When the old "Division of Tests," renamed the "Office of Public Roads," began to operate along the lines now followed it became evident that the generation on the stage of action to-day would be walking the streets of the New Jerusalem long before any great advance in the cause would be made from that influence. I was present at many conferences in different and widely separated cities, where men who had been actively engaged in the work discussed plans for forming an association to take up the work and conduct a campaign for good roads on a general method akin to that followed in a national political campaign.

It seemed to be a logical scheme of organization to unite in the executive board of such national organization all interests, which

A FRENCH ROAD IN EARLY SPRING—NOTE ITS EXCELLENT CONDITION—MATERIAL FOR REPAIRING IS PLENTIFUL.

And all this was on the main highway connecting the two most beautiful cities of California, whose centers are scarcely a dozen miles apart. The millionaires of these two cities might build an Appian Way along this road and never realize that they were out a cent. The owners of property along the road might contribute the funds to make it a perfect highway and find their assets actually increased in spite of the outlay.

It is just a phase in the period of evolution towards full civilization in America. It is comforting to realize that others who have made greater progress had to pass through just this stage.

But to the readers of THE AUTOMOBILE there are other still more inspiring reflections. It is just because these automobiles stick, and throw mud, and bring to those who attempt to ride in them unspeakable grief that this present frenzy for something better has come about. It is on and will stay on till the automobiles get emancipated. I have seen it coming and done what I could in a humble way, here and there, to inflame it.

Studied Good Roads Movement for Seven Years.

Having studied the good roads movement intimately the past seven years all over the United States, I have had exceptional opportunities to watch its growth and its changing phases. I was present in Portland, Ore., at the convention in June, 1905, when

would be pecuniarily benefited by road betterment. On such board the automobile, carriage, farm vehicle, street paving, brick making, and very many other industries would have representation. So far as I know this idea was never carried out.

Time for Autoists to Make Road Question Their Own.

Meanwhile industrial history has been making rapidly. If I read aright the signs of the times, the hour has come for the automobile interests to take up the road question as *their question*, and to deal with it as a *sine qua non for them* and one which for that reason they are going to take sole charge of and solve. The time has passed when all mankind was divided into two parts: one, an insignificant minority, using the death-dealing go-devil as a luxury, with reckless disregard of their own or their neighbor's anatomy; the other, the balance of the human race, whose sole interest in these infernal machines arose through a common instinct for self protection. In less than half a score of years they have jumped from a position of tentative experiment to a place beside the steam engine as an indispensable requisite in the world's progress.

When the automobile captured the farmer it had conquered the world. The hayseed of other days may once have been correctly depicted in overalls and whiskers upon the board seat

of a rickety wagon, holding the lines over a pair of venerable plugs. The passing of this type is, in my mind, the most important fact of the Twentieth Century to date. The farmer of to-day is the nabob. His mortgage has been paid off, he has money in the bank, travels for pleasure, and rides in an automobile. Not all of him, but enough to indicate with certainty the economic changes which are imminent. From this time on his interests square absolutely with those of the rapidly augmenting element to which the motor car has become an indispensable necessity. In the conquest, which is just ahead, for the commercial vehicle, the farmer will be strictly in it. The truck car will haul his products to rail or water; with motor devices he will plow, plant, sow, and till his fields and gather his harvests. It is easy to see what the commercial vehicle will do in every line of work.

Automobile Needs and Should Get Roads.

Having now reached the period when the motor car industry affects every possible department of human activity, what could be more logical than for that interest, as such, to take up the road question and proceed to solve it? No one can say longer that the automobile interest should hold itself in the background lest it arouse antagonism. The automobile interest has become IT in the world. The Automobile needs good roads. It should combine its forces and get the roads.

Just how that should be undertaken, I am not prepared yet to say. I think the first thing is for those interests to announce boldly that the time for hesitancy has passed, the time for action come, and that the automobile people—makers and users—are going to see that the necessary legislation is enacted, the necessary money raised, and the roads built.

I have always felt myself that a central organization should

have general charge. Hasn't the time come to take up the subject in the executive bodies of your great organizations, and to consider it as a need which you will have satisfied?

And now, reverting again very briefly to the condition which furnished my text: "The needs of California and the movement now started for relief."

By reason of its topography and climate, California has an opportunity to furnish a more striking object lesson of American possibilities than any other section of this continent. The world would be searched in vain for such a pleasure ground twelve months in the year as California would become with a complete system of good roads. So great would be the attraction that even kings would leave their thrones and hasten to try the delights of automobiling among the orange groves and gardens, the fields and the missions, the seashore and the mountains, the luxurious cities and the beautiful towns. No man who loved the exhilaration of the swiftly gliding car would be content until he had come to this enchanted land and seen for himself, and when he went back home he would carry with him the story of what could be done to make this earth a paradise.

A preliminary convention was held last week to devise ways and means to make a start. The laws of California are very backward in their provision for roads. A bill framed on the lines of the New York State aid law will be drafted and an earnest effort made to get it enacted. The legislature is in session. What is done must be done quickly. I have no special interest in California, but I have given the best of my life to this cause, and I want to see it win. Because I so feel I beg you and all my friends who will read this to do what you can to so shape sentiment in this State and to so enlighten this people as to their true interests that such law may be passed.

CONNECTICUT ROAD COMMISSIONER'S PERTINENT REPORT

NEW LONDON, Conn., March 4.—In the abstract of the two years' report of State Highway Commissioner James H. MacDonald, presented to the governor, the question: "What injurious effects, if any, do automobiles have on our road system?" is discussed affirmatively as follows:

At home and abroad this question has been asked any number of times, and I have thought it of sufficient importance to reply to it in my report. It is astonishing how popular motoring has become in our State, and, in fact, all over the United States. Since the issuance by this State of the first license on May 28, 1903, up to the present time, 4,000 licenses have been issued by the Secretary of State. About 400 of these licenses are for motor cycles and about 300 licenses have been issued to transients. No license fee is charged non-residents unless they are to remain in the State for a period exceeding fifteen days. The sum of \$2 is charged for a license. This fee, it is apparent, is only nominal, and the income derived from this source does not amount to a very large sum in the aggregate. The use of the automobile, it must be conceded, will grow rapidly, and, as automobiles have come to stay, the use of the roads by this class of vehicles will form a very large part of the traffic over the highways of the State. If it be true that so many citizens own automobiles and use the roads for business or pleasure, it is equally true that the number of persons using the roads is augmented several thousand by those who come into our State, this latter class contributing nothing to either town, city, county, or State treasury.

Now, the vital question is: Does the automobile injure our roads more than the travel of other vehicles? If so, in what way? It is only fair to take this question up broadly so as to reach a fair conclusion in determining this factor in the solution of this newer problem confronting us in the use of the highways. I have made a close study of this question during the past two years, and I am satisfied that no agency at work on the roads has directed attention to the use of our roads to the extent that the automobiles have. The natural inquiry will be, in what manner has this been done?

It is safe to say, in reply to this inquiry, that our roads have shown more wear on the surface during the past two years than for any similar period since the commencement of macadam construction in this State. In nine out of ten towns artificial moistening of roads is not resorted to by the officials in towns where our

macadam roads have been constructed. The use of the sprinkling cart seems to be a lost art, and the only moisture the macadam receives is from the rain and the dew, except, of course, in winter time, when there are occasional snow storms. For that reason our macadam roads are very dry in summer and become an easy prey to rapidly moving automobiles. The low-hanging machinery of the car restricts the space from the top of the road to a narrow opening which the rapidly moving car transforms into a draft, the suction from which removes all loose or insecure particles from the surface of the road, very much as a carpet sweeper operates.

The screenings top has two useful purposes. One is to form a cushion to protect the second course of stone, which is the top course of stone immediately under the screenings or finishing surface of the road. This cushion protects the underlying stone from direct contact with the shoe of the horse and the tire of the wagon. Its second office is to retain moisture in the summer time, thus preserving the cementic properties of the screenings, and in the winter time furnishing a covering that prevents the entrance of frost into the road, and also removing the possibility of disintegration and heaving of the road screenings. It also operates to prevent the fall rains from penetrating into the courses of stone, thus inviting frost, and leaving the road, when the frost departs, green and very susceptible and responsive to travel.

In the summer time, particularly, when our roads are very popular and are used largely by all kinds of vehicles either for business or pleasure, the passing of one of these rapidly moving cars removes from the road its intended protection. Horse-drawn vehicles that follow are, by this stripping process, brought into direct contact with the stones that have been uncovered by the automobile. These stones are early dislodged from where they were imbedded, and a fracture is made in the road. The stones thus loosened act as an irritant to the other stones when struck by hoof or wheel, the bond is thus broken and the road immediately demands repair, or a large bill of expense will result. If the road is not at once taken care of the influence of even a slight fracture is far reaching. This destructive force has been at work for some time, but its effects have been more noticeable during the past year than ever before.

This description of how roads are injured is apparent, not only to the men who make a business of the art of road building, but is the subject of grave consideration in towns where a macadam system has been laid. All over the State where we have a macadam system officials are inquiring how to remedy the evil.

ACCUMULATORS FOR ELECTRIC IGNITION

By CHARLES B. HAYWARD.

As already outlined in a previous part of this article, the process of accumulator charging and discharging is not a mysterious form of storage for the electric current as popularly supposed, but is purely one of chemical conversion and reconversion. But it is not necessary that the autoist should be an electro-chemist in order to be able to understand or properly take care of a set of accumulators, and it is accordingly not intended to go deeply into that side of the subject here. Nor will the matter of history be gone into further than to state that the discovery that a current sent through a voltaic couple consisting of lead plates immersed in dilute sulphuric acid, set up a chemical

action which could be reversed and a current drawn from the cell, marked the inception of the accumulator or storage battery. That was more than half a century ago and though numerous combinations of other materials have been tried in the interim, none proved practical in a commercial sense until the discovery of the nickel-iron combination in an alkaline solution by Edison. As all the accumulators now on the market for ignition purposes are of the older type, it will be unnecessary to consider any other than this, though it may be added that the characteristics of any accumulator are bound to be very similar regardless of the materials used in its construction. Any form of cell which is reversible—that is, from which a current may be redrawn, after charging it—is, properly speaking, an accumulator, some primary forms having this characteristic, but only in a very slight degree and not sufficient to render them of any value whatever for this purpose.

FIG. 1.—Helios Cast Grid before pasting with the active material.

materials used in its construction. Any form of cell which is reversible—that is, from which a current may be redrawn, after charging it—is, properly speaking, an accumulator, some primary forms having this characteristic, but only in a very slight degree and not sufficient to render them of any value whatever for this purpose.

How Accumulators Are Made.

In order that the autoist may not only have a thorough understanding of the subject, but also be able to understand why it is important that an accumulator should be cared for in a certain way and certain things avoided, it is essential to have a knowledge of how an accumulator is put together. In this connection, he should bear in mind those elementary principles that were outlined in the first part of this article as they are directly involved. So far as its essentials are concerned, the statement that an accumulator consists of two lead plates immersed in dilute sulphuric acid, suffices to define it, but it is evident that two sheets of lead dipping into a jar of electrolyte could not very well be carried on the car, so it will be evident that the remaining considerations are purely mechanical. Mention was made of the fact in a previous part of this article that originally accumulators were made by what is termed a forming process. That is, metallic lead plates with smooth surfaces were placed in the electrolyte and "formed" by passing a current through them; in other words, by electro-chemical means. This is known as the Planté type of plate. It has been almost totally superseded by what is known as the "pasted plate," or Faure type. In this, the foundation consists of a grid consisting of pockets or recesses into which the active material is pasted by hand and solidified under pressure. Each method has its advantages, depending upon the service for which it is intended, and it will be found that both are used for auto-

mobile work, though the pasted type practically monopolizes the field, the "Invincible" being the only formed type for ignition use.

Numerous Processes and Types of Grids.

There is absolutely no end to the number of methods of forming or to the types of grids at present on the market, many of the processes being well-guarded trade secrets. It would be of no advantage to attempt to review even the best known types, so that this matter is gone into only to an extent sufficient to illustrate the fundamental principles and methods of construction embodied in every standard accumulator. It was not long after the original discovery of the principle of the accumulator that it was found possible to greatly increase the activity of a simple cell by surrounding the positive plate by the negative; that is, in order that both sides of the positive plate might be active. This accounts for the use of one more negative plate in every accumulator, as in this way both sides of all the positive plates are utilized and the capacity of the battery greatly increased. When the charging current is sent through a cell, the active material, peroxide of lead in the case of the positive and metallic lead in a spongy form on the negative, expands and the electrolyte also changes its density. On discharge, the converse takes place and this expansion and contraction take place to a marked degree, proportionate to the size of the plates. For this reason every cell has a safe charging rate and a safe discharging rate, and greatly exceeding it, particularly in the case of the discharge, causes the plates to warp or "buckle," as it is usually termed, either forcing the active material out of the retainers or bending the plates so much that they come in contact with one another.

The capacity of a battery not only depends upon the square surface presented to the action of the electrolyte, but also to the porosity of the active material and its conductivity. The maker is thus confronted with the problem of making the active material loose and porous and at the same time hard and resisting in order to stand the shocks of usage, without falling out of the plate. The illustrations of the few types of grids shown will suffice to give

an idea of the method of retaining the active material. The first, Fig. 1, is the grid of a Helios cell, while the second, Fig. 2, is that of a Toledo cell, made from chemically pure sheet lead, the completed plate being so flexible that it may be rolled upon itself; many makers employ a composition of antimony and lead in order to secure stiffness, the grids being cast, while others are made directly from sheet lead under heavy pressure. Those referred to are the pasted type. One of the few cells that is made in small sizes by the forming process is the Type H "Invincible" cell, the construction being such

FIG. 2.—Toledo Pressed Plate; made from chemically pure sheet lead.

that the active material is retained by gravity. This type is intended particularly for automobile and marine ignition work, though the method of making renders them more expensive. It will be obvious that in any portable type of cell, such as that required for electric vehicle and ignition work, the chief requisite will be large capacity without undue bulk, and to obtain this the plates are placed as close together as possible. In order to insulate them thoroughly and still permit of the active circulation of the electrolyte upon which the working of the cell depends, grooved wood separators and

perforated hard rubber insulators are employed, a typical group of these parts being shown by the illustration of the Autex plates and separators, Fig. 5, and also by the dismantled unit of the Look cell, Fig. 6. In some small cells, such as for ignition, it is possible to place the plates sufficiently far apart to dispense with separators of any kind as is done in the case of the "Reliance" cell—about

FIG. 3.—Cross section of plate for forming

FIG. 4.—Section of American Cell showing components.

the only one made in this country that employs a celluloid containing case.

General Requirements.

An idea of the requirements of the completed cell, other than those already mentioned may be gained from the illustration of the section of an American cell, Fig. 4. This is an end view of the cell and shows that the group of plates is not permitted to rest upon the bottom of the containing case but is elevated therefrom. The supports shown are square strips of hard rubber and the necessity for so placing the plates arises from the fact that the active material is constantly disintegrating to a greater or less extent and falling to the bottom of the jars. As it is a conductor, it would short-circuit the plates if allowed to come in contact with them; for this reason provision is made to allow it to drop free of them. It will at once be apparent that if sufficient of it falls to make a pile that reaches to the plates, the cell will be put out of action. The terminals extending through the case are of the same material as the plates—sheet lead—as any other material would quickly corrode from the acid fumes. In both the process of charging and discharging, hydrogen and oxygen gases are evolved by the cell, so that the necessity for sealing it to render it conveniently portable is complicated by that of permitting the escape of the relatively large quantities of gas produced. Many patented devices are used for this purpose, that shown being a combination soft rubber and glass valve. As only that part of the plates that is immersed in the electrolyte undergoes the changes mentioned and the unequal expansion and contraction would quickly ruin them, it is essential that the solution should cover them at all times, as is shown by the illustration. When a cell is charged rapidly so much gas is evolved that it creates more or less pressure and results in spraying some of the acid out the vent hole. This settles on the connecting lugs and corrodes them; such deposits should be removed with warm water, or a solution of ammonia and water; if this trouble continues the corrosion may be prevented by coating the terminals with vaseline or other heavy grease. With the exception of the outlet provided by the vent, the remainder of the top of the cell is hermetically sealed.

Rating and Its Significance.

Accumulators are always rated in terms of ampere hours—this is known as their capacity and, as already stated, it depends upon the size and number of the plates. By ampere hours is meant the

length of time during which the battery is capable of giving a discharge of one ampere per hour; for instance, a 60-ampere hour battery—the size most often used on the automobile—is capable of giving a discharge of one ampere for 60 hours, 2 amperes for 30 hours, 3 amperes for 20 hours, 6 amperes for 10 hours, and so on, but there is a limit to the rate at which it should be discharged, although some makers, such as the Autex, claim that the discharge rate may be anything desired, and the Toledo, for which it is claimed that a dead short-circuit will not injure the plates, so that these two manufacturers do not caution the user as to the safe discharge rate of the cells. The amount of current demanded by the ordinary ignition system is so small that there need be little fear on this score except when things are in such poor shape as to run the battery down in a few hours—something for which the battery is most often blamed, though not at fault.

The charging rate of a cell is usually the same as its safe discharge rate and should not be greatly exceeded, if good service and long life is expected from the battery. Just what its safe discharging and charging rates may be are usually given by the maker. With all due respect to those makers whose cells will stand a dead short-circuit when fully charged, the autoist is most strongly advised against subjecting his battery to any such test, even when his only object is to see whether it is "loaded" or not. As received from the maker, the battery is usually fully charged and ready for service. Provision for recharging must be made in accordance with the available current supply. The latter must be direct current, as an alternating current cannot be used for charging owing to the fact that it pulsates, first in one direction and then in the other, so that no matter how long a cell were connected in an alternating current circuit it would not have any more current in it at the end than at the beginning. Having ascertained that the current supply is direct, the next essentials are to determine its voltage and its polarity. The former may usually be found on the labels used on the incandescent lamps, or from the central station; the polarity will have to be determined at the point the current is to be used.

Various Methods of Charging a Cell.

The direction of the current having been ascertained, whether by a pole indicator, pole indicating paper or no other means being at hand, by dipping the bared ends of the wires into a glass of water a short distance apart, the one from which the greatest number of bubbles are given off being the negative, provision must be

FIG. 5.—Typical group of plates, separator and insulator.

made for sending the proper amount of current through the battery. The methods of doing this are illustrated by the line sketches. Where the service is 110 volt direct current, the battery may be connected in series with a group of lamps in multiple. Fig. 7. At this potential each lamp takes approximately half an ampere of current, so that twice as many lamps as the number of

FIG. 6.—Components of Look complete unit ready for assembling.

amperes called for by the charging rate of the battery will be required; where the service is at 50 volts—rarely used nowadays—half the number of lamps will be needed, and at 220 volts double the number, as shown connected in series-multiple, Fig. 8. The sketch, Fig. 9, shows the method of charging from what is known as a three-wire system, in which two 110-volt generators are used

FIG. 7.—Wiring diagram for charging from 110v. direct current with incandescent lamps as resistance.

on three feeders. Any two except the outside pair will give a potential of 110 volts, so that connections may be made as shown; in this the resistance has been omitted, the instrument shown being a circuit breaker to cut out the battery should the charging current cease. Unless provision of this kind is made, the cell will discharge should the generator stop. In Fig. 10 a method of charging from a low voltage generator carried on the car and which is also used for ignition current directly, is shown; when the switch is on the upper point, the battery is supplying the coil and is being charged at the same time from the dynamo; should the motor stop the automatic cut-out prevents the battery from discharging through the dynamo and when it starts again the battery must be connected to receive the charge. On the lower point, the dynamo supplies current directly to the coil. Figure 11 shows an improvement on this method, employing an automatic switch; in this case, the switch takes care of the charging current at all times and the current for ignition is always taken from the battery. This is the method used in the Apple system, the wiring diagram of which is illustrated in Fig. 12, a volt-ammeter being mounted on the panel to give the charging rate and the voltage of the cells.

Shortly after being placed on charge, the voltage rises to 2, quickly increases to 2.2, and then gradually rises to 2.3, at which what is commonly known as "boiling" begins, but which, as already mentioned, is the evolution of hydrogen and oxygen. Above this voltage it becomes very active and the cell actually appears to boil, the ebullition is so strong. The charging should not be continued after the cell shows 2.5 volts while on charge; immediately after disconnecting the reading will be considerably less. In the case of the three-cell battery this means that when approaching repletion the battery itself has a potential of about 7.1-2 volts, so that the source of charging current must be higher than this, otherwise the battery will neutralize it, and either discharge back through the source of current by reversing its polarity or cease to charge. Bubbling is not a certain test of the state of the charge nor, for that matter, is the use of an ordinary pocket voltmeter, or a small lamp. The only really accurate test is that of the specific gravity, the density always being a good indicator

of the state of the cell, the electrolyte becoming lighter as the charge proceeds and heavier as the cell discharges. When fully charged, the proper density is 1.225 and 1.125 when practically exhausted.

Caring for Accumulators.

Both the service to be had from an accumulator and the length of its life will depend upon the care given it. There are numerous cases on record where an accumulator has served for an entire season with but a single recharging and some instances where it has not been recharged at all during that time, but whether used steadily or not, it is a good plan to charge more or less frequently at a low rate once a fortnight or once a month, as this keeps the cells in better condition. It must be borne in mind, moreover, that ignition work is about the most exacting service that an accumulator is called upon to perform; it is seldom called upon to work steadily for any length of time, it is given but little attention and the conditions of service are all against it. The vibration and jolting hasten disintegration and are apt to cause the active matter to loosen, and defects in other parts of the system are apt to run down the cells in a short time so that caring for the accumulator really involves the care of the remainder of the ignition system more than it does that of the battery itself, for if the latter be kept properly charged it will seldom fail to give satisfactory service, other conditions being favorable. For instance, the average coil when in good working order only requires .50 to .75 of an ampere, and a 60-ampere hour set of accumulators when working on such a coil should accordingly give the equivalent of 75 to 120 hours of continuous service. When it is found that it gives but a fraction of this, a defect should be looked for in the wiring system rather than in the battery itself, and the misplaced remedy of using more current than is necessary should not be resorted to; if the system will not run on less than one ampere there is something wrong with it. The cells should be tested with a low-reading voltmeter while the motor is running, as it is one of the peculiarities of the accumulator that it will apparently recuperate on open circuit and show a comparatively high voltage reading though practically exhausted. The coils should also be tested with a low-reading ammeter and adjusted to take the minimum amount of current. The voltage test on the accumulators should be made from time to

FIG. 8.—Charging from 220v. direct current with 110v. lamps as resistance.

time so as to guard against running them down too much; when found to be in the neighborhood of 1.8 they should be recharged without delay. If this be not done the battery is apt to stop working very abruptly, and then usually everything else but the cells will be suspected. The latter should never be tested with an ammeter, which short-circuits them, or in any other way by

FIG. 9.—Method of wiring for charging from a three wire system with automatic cutout, no resistance shown.

short-circuiting them, such as placing a screwdriver across the terminals. It is harmful to the battery and in the case of the ammeter is apt to be so to the instrument also.

Some Questions Answered.

The following are a few of the questions that continually crop up, these being taken from the letter of an autoist seeking infor-

FIG. 10.—Charging directly from a low voltage generator carried on the car

mation on the subject: "What is the duration of life of the accumulator?" This is something that cannot be answered definitely, for with reasonable care accumulators have been known to give steady service for several years and still test close to standard requirements at the end of that period, while in other cases they have lasted but a short time. It is somewhat akin to asking

FIG. 11.—Wiring diagram for dynamo and accumulators on car, using automatic switch, usually mounted on dashboard.

how long a man should live. "When partially discharged and standing quiet, will they run down like dry-cells, and why?" Some makers claim that their cells may be left partially or wholly discharged indefinitely without harm, but the average accumulator runs down under such conditions and loses in efficiency because of the formation of sulphate of lead on the plates which covers them and insulates them from the action of the electrolyte. The so-called running down is due to what is known as local action; that is, the cell works internally while not in use and this cannot be wholly prevented. "How far can they be discharged safely, and why not more?" Both parts of this question have already been answered, the former in this part of the article and the latter in the one that preceded it. Absolute exhaustion is considered to

occur when the cell only registers 1.7 volts under load; that is, sparking the motor or other duty, and the reason why it is not safe to go below this limit, as already pointed out, is that the formation of sulphate of lead would occur to an extent where the cell would be ruined. "How can some batteries give more ampere hours than others, as advertised?" This has also been answered; merely because they have a greater amount of surface. "What will cause short-circuiting in the

FIG. 12.—Connections of generator and accumulators with automatic switch as employed in the Apple system.

battery?" The loosening of the active material to such an extent that it piles up on the bottom of the cell to the level of the plates or is caught between them. As most ignition accumulators are hermetically sealed in opaque cases, there is no way of telling when this has occurred. The best remedy is to return the battery to the makers. "Why do plates buckle when not charged properly,

and what is the remedy?" This, also has been explained in the foregoing. "What is the average mileage of a battery with a high-speed four-cylinder engine?" Probably a good average would be 800 miles, but there are cases innumerable where this has been greatly exceeded, and, as already stated, everything depends upon the condition of the ignition system itself, the coils, timer, plugs, etc. It is nothing uncommon for a battery to serve for 1,200 to 1,500 miles' running, though it is equally common for them to give out at the end of less than 500 miles, but the fault usually lies with the driver rather than the battery. To sum up, given reasonably good care, which means proper charging, maintaining the electrolyte above the plates by replenishing with distilled water and attention in other ways already pointed out, a good battery will last three or four years and give excellent service.

INCREASE IN AUTO PRODUCTION.

In the course of five years, as revealed by a statement recently made public by the Census Bureau, the production of automobiles in this country rose from 3,723, with a value of \$4,748,011, to 22,830, valued at \$26,645,064, the first figures representing the output in 1900 and the second, those of 1905. This represents an increase in value of 261.1 per cent. Of the 21,692 cars turned out by regularly established factories no less than 18,699, or 86.2, were driven by gasoline; 1,562, or 7.2, by steam, and 1,425, or 6.6 per cent., by electricity. A total of 121 establishments is reported as building complete cars and nothing else, besides which there are 47 primarily devoted to the manufacture of some other line, such as bicycles, sewing machines and the like. During the year covered by the census these factories turned out 1,138 automobiles, valued at \$879,205, and there are in addition 57 factories which manufactured automobile bodies and parts to the value of \$3,388,472.

The total number of cars made is again subdivided, and it is interesting to note that 12,131, or 55.9 per cent., were of the runabout type; 7,220, or 33.3 per cent., were touring cars. Buckboards came next on the list, with a total of 675; Stanhopes fourth, with 520, and delivery wagons fifth, with 411. In the period between the years 1900 and 1905 the number of factories turning out finished automobiles as their principal product increased from 57 to 171, and the capital invested in these establishments from \$5,768,857 to \$20,555,247; in the same time the average number of employees rose from 2,241 to 10,239. The value of American made machines exported increased from \$9,8528 in 1902, the first year they were separately reported, to \$2,481,243 in 1905, or a gain of more than 250 per cent.

ON FAKING CASTINGS.

W J. MAY IN THE ENGLISH MECHANIC.

The cost of a finished casting must, to some large extent, depend on the cost of the metal, or metals, of which it is composed, and therefore for a good many purposes the cost of the castings will be found to vary from time to time. Now, at the present time, copper, tin, zinc, and antimony are high in price; consequently brass and gunmetal and other alloys must be higher in price if the weight and quality be the same as when the component metals are cheaper. Of course, the expert metal-mixer can "fake" his mixtures, and in many cases "load" them with lead, proper treatment making it quite impossible to detect the tricks unless chemical analysis be resorted to; but, as a rule, metals which are faked up do not stand wear well, and although the prices of castings per pound may be kept down, really the increased weight of each casting counterbalances any saving there may be in the cost per pound. In fact, it often happens that castings at, say, one shilling per pound, actually cost less than others at eleven pence per pound, and this simply because the more expensive castings weigh less than the cheaper ones.

Lut in addition to this the difference in initial cost will be found to be more than offset by the greatly lessened service to be obtained from the cheaply loaded alloy.

ELECTRIC VERSUS MECHANICAL TRANSMISSION

By E. W. HART AND W. P. DURTNALL.

ONE of the most attractive subjects connected with the automobile is the transmission of power to the road wheels. The subject is a very large one and for thorough treatment would require more space than is available in this paper. Next to the engine, the power transmission is the most important thing about the vehicle, and bad design may make a great difference in the power obtained at the road wheels. It has been proved, by actual tests, that fully one-half of the power developed by the engine is often lost in undue friction between the prime mover and the wheels. The system mostly used at the present time is, in reality, a group of three or more rotating levers, providing not only a reduction of speed but also a fairly proportionate increase of torque at the slower vehicle speeds, something which is absolutely necessary, especially when climbing severe grades. But it must be admitted that beside having other disadvantages this system is exceedingly noisy when the gears are worn. We feel sure that it will be universally agreed that if the gear box can be satisfactorily eliminated it will be a welcome improvement.

Electrical Power Transmission.

That otherwise ideal prime mover, the internal combustion engine, has one great fault: it is wanting in elasticity, and, in order that it may be satisfactorily adopted, some sort of variable speed-changing device is necessary. In gasoline-electric systems, the arrangement usually employed is that of a dynamo coupled

HART-DURTNALL GASOLINE-ELECTRIC BUS CHASSIS.

direct to the engine and furnishing current for a motor coupled mechanically to the road wheel. The vehicle is, actually, an electric car having, in place of the usual battery a generator set. But a true gasoline-electric car is not restricted to any radius of action and requires no re-charging. Probably the earliest system employed was that of Patton (1890) in America, using street cars carrying accumulators and employing a small gasoline engine and dynamo to charge the battery. The engine was always run at full load, the current being taken from the battery for the two electric motors. Beside being complicated, the efficiency of such a system was low.

In the Dowsing system a shunt-wound dynamo was employed, both engine and dynamo being belted to the road wheels and so arranged that the surplus power from the engine was converted into current by charging a battery. When the speed fell below normal the dynamo became a motor, fed from the battery and assisted the engine on inclines. This system showed a higher degree of efficiency than that of Patton. In the Germain system the dynamo field revolved round the armature and the torque there produced was utilized in connection with the current generated to start the car. This permitted a good portion of the mechanical power of the engine to be transmitted direct to the road wheels. A switch was closed in starting, permitting the field to build up and, with the motor, producing full torque. Then the resistance was thrown in shunt with the motor, thus gradually

cutting it out and causing the speed to rise. The dynamo being series wound, when the difference in speed between the field and armature was small, it formed a powerful magnetic and flexible coupling, varying in accordance with the demands made upon it.

The Hart and Other Systems.

The Hart system, first introduced in 1903, consisted of a 40-horsepower gasoline engine directly connected to a compound-

DIAGRAM OF CONNECTIONS, HART-DURTNALL SYSTEM.

wound dynamo. The current generated was sent through a series-parallel controller, to a motor having two distinct windings on both field and armature. Various speeds were thus obtained, the motor being geared by a single reduction to the differential countershaft and a double side-chain drive being employed; for low speeds a metallic resistance in series with the motor was used. This was the first high-powered gasoline-electric car built and has only just been exceeded by the 45 and 70-horsepower car of the Mercedes Electric Company. With a touring body, it weighed under 2,500 pounds and easily attained a speed of 50 miles per hour.

The Fisher system consists of the usual continuous-current generating set, the dynamo being connected, through a series-parallel controller, to two 7 1-2-horsepower series-wound motors, each coupled through a double-reduction spur and pinion gear to the rear wheels. Surplus current is utilized for charging a set of 150 ampere hour accumulators. With complete equipment this vehicle weighs over 7 tons.

A heavy lorry of this type was taken and converted to the Hart-Durtall continuous-current system. The battery was eliminated and the winding of both generator and motor altered so as to provide for about twelve different speeds, or torque values. The connections as now used are shown by the cut. Assuming that the engine runs the dynamo at constant speed in the switch position shown, no current is generated as no field windings are in circuit. By moving the switch along the contacts the field winding comes into circuit and a low E.M.F. is generated. Current goes to the motor, producing sufficient torque

GERMAIN SYSTEM AND DIAGRAM OF CONNECTIONS.

to start the car; owing to the voltage building up very gradually, starting is much more smoothly effected than is possible with the constant-voltage and series-parallel method. To increase speed it is only necessary to move the switch further, cutting out some of the field windings and raising the voltage; for hill climbing a central position of the switch permits the greatest amount of power to be transmitted with full field on both dynamo and motors; for very steep hills some of the dynamo windings

*Extract from paper read before Society of Motor Omnibus Engineers, London.

CHASSIS EMPLOYED ON THE CAROLAN SYSTEM.

can be cut out, giving a heavy current at lower voltage and producing a heavier torque at lower speeds at the road wheels. The main circuit is never opened, and as the field sections are short-circuited on themselves, no detrimental astatic discharges take place; for a sudden stop, the dynamo field is bridged over, and the magnetic field immediately lost; thus all power is shut off without altering any connections before the brakes are applied; immediately the brakes are off the field is opened again and the dynamo voltage gradually rises, securing perfect starting with constant acceleration.

Some Continental Systems Considered.

The Lohner-Porsche system has recently been adopted by the Mercedes Electric Company, the motors being placed in the hubs of the rear wheels. This disposition cannot be accepted as an efficient one; our experience shows that after a few hundred miles on rough roads the brush gear requires costly attention owing to the chattering of the brushes on the commutator. To reduce this as much as possible the 12 sets of brushes in each motor are thrust on horizontally, which is not an economical form of construction.

The Krieger is what is known as a constant-power system and it has been employed on quite a number of cars. The principle is that of maintaining a practically constant Watt output, *i. e.*, a small current at high voltage for speed on the level, or a heavy current at low voltage for hill climbing. No series-parallel working is utilized. In the wiring diagram, *A* is the dynamo armature; *B*, the self-exciting shunt winding; *C*, independent exciting winding, also on dynamo field; *D*, accumulators for maintaining excitation and running dynamo as motor to start engine; *E*, resistance controlling charging current when running; *F*, series-winding arranged to demagnetize dynamo field; *G*, motor armature; *H*, series excitation of motor; *I*, demagnetizing coil excited by dynamo armature. This is an ingenious method of transmission, the use of but one dynamo and one motor arguing well for efficiency.

The Pieper system, known in England as the Auto-Mixte, employs a single dynamotor and a set of accumulators. The dynamotor is direct-connected to the engine and electrically through a controller to the accumulator; it works as a dynamo or motor according as its E.M.F. is inferior or superior, to that of the battery, yielding additional power for propulsion when climbing. The battery is also used for ignition and to run the dynamotor to start the engine; this current also is used to automatically throttle the engine. The dynamotor is fitted with commutating poles, the windings of which are in series with the armature, insuring good commutation with heavy currents, and with a weak main field.

Characteristics of English Systems.

The Astle-Wallis is an English system that appeared in 1901. It consisted of a 10-horsepower, two-cylinder engine coupled through a friction clutch to a four-pole shunt-wound motor, and a set of accumulators. To start, the motor was run from the accumulators; as soon as the engine came up to half normal speed it automatically began to charge the battery; then by means of a planetary gear the car was practically started on the direct drive

after which the motor aided the engine to accelerate the car's speed. When running at normal speed the surplus power ran the motor as a dynamo and charged the accumulators. On hills this was reversed, the dynamo running as a motor and assisting the engine, the whole arrangement being automatic. An eight position controller embodying a carbon break-switch was employed; this severed the circuit when the brake was applied and did not close it again until the controller was placed in the off position. Running down hill the clutch was withdrawn, and the engine stopped, the kinetic energy of the car being utilized for charging.

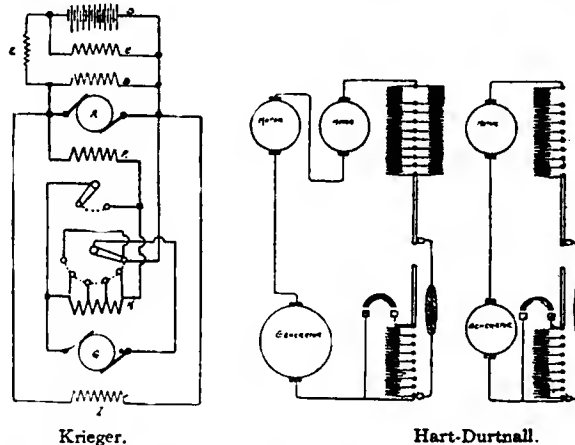

The Stevens is a continuous-current system utilizing two electric motors with the series-parallel method of control on both the motors and the dynamo, the latter being double wound with two commutators and two separate field windings. A pedal-operated resistance opening the main circuit when changing speed is employed to prevent sparking. From an electrical point of view this system has many good features, as in climbing, the dynamo winding can be put in parallel and the engine run at full speed, while the car travels at about quarter speed with the motors in series and with increased torque at the road wheels.

Details of the Hart-Durtnall System.

In all the systems previously dealt with, as well as those illustrated here, to which no detailed reference is made, continuous current is utilized. In the Hart-Durtnall system, polyphase, alternating-current apparatus is adopted. Chief among the advantages of the induction motor are its powerful starting torque and its freedom from commutator and brush troubles; a burnt-out armature is practically unknown. It also has the advantage of being able to start against load in contrast with the single-phase motor of the same type. As is well known, such a motor consists of but two parts, the stator and the rotor. When running light the speed of the motor is very nearly that of the rotating field produced in the stator or nearly synchronous, a very small current being induced in the rotor winding; its magnetic pole on the rotating field produces a feeble torque, and the current consumption is only that required to overcome the mechanical and magnetic friction of the motor.

The method of varying the voltage is that of changing the number of poles of the stator and so arranging them that, although the periodicity of the supply current remains constant, the motor can turn at quarter, half, or full speed. The result is very similar in action to, though much more flexible than, an ordinary set of change speed gears. Other great advantages are absolute freedom from danger of mechanical injury and the small amount of insulation required on the rotor.

We show, diagrammatically, a general arrangement, in plan and elevation, of the Hart-Durtnall chassis. *A* is a 40-horsepower engine (speed, 800 r. p. m.); *B*, fan; *C*, polyphase, alternating-current generator, combined with a series-wound exciter; *D*, electro-magnetic clutch, to obtain direct drive on top speed (800

WIRING DIAGRAMS: KRIEGER CONSTANT POWER AND HART-DURTNALL CONTINUOUS CURRENT SYSTEMS.

r. p. m. of engine equals 12 m. p. h.); *E*, polyphase, alternating-current, induction motor, coupled by means of—*F*, propeller shaft, fitted with universal compensating joints to—*G*, live back axle, fitted with differential gear, etc.; and *H*, bolts to carry the whole plant, which is slung from the cross members of the chassis.

Other parts shown in the diagram are: *I*, connections; *J*, exciting, revolving field-magnet of polyphase-current generator; *K*, armature of small, continuous-current, series-wound exciter; *L*, sectional field of exciter; *M*, winding of electro-magnetic clutch; *N*, regulating switch and contacts in connection with sectional field; *O*, bridge contact-piece, for short-circuiting generator field;

SIDE ELEVATION CHASSIS OF PIEPER SYSTEM.

P, contacts for bringing into circuit magnetic clutch windings; *Q*, fixed armature winding in polyphase generator; *R*, fixed "stator" two-speed windings; *S*, "rotor" of polyphase motor, with short-circuited bar winding; *T*, bridge contact in connection with the foot-brake pedal; *U*, reversing switch; and *V*, two-speed switch, for starting on gradients.

The method of operation is that, assuming the engine is running at constant speed, the switch is on the forward position, the two-speed switch is on the top electrical driving speed, and the regulating switch is on position 1, no voltage being available, the driver places the switch on No. 2 contact, and a low voltage is generated, which excites the alternator field, which, in turn, generates polyphase alternating current in the generator arma-

ture-winding, from whence it is conducted, by copper bars, through the reverse and two-speed switches to the "stator" winding in the motor, producing a rotating field in the "stator"; the "rotor" then starts and endeavors to get into phase with the speed of the generator. Should the car be loaded, it may be necessary to increase the field of the exciter, in order to get sufficient starting torque at the motor, and this is done easily by bringing the switch round to No. 9 contact; when the speed of the car has risen, direct drive is obtained by moving the switch on to No. 10 contact. This move drops the magnetic clutch winding in series with the field of the generator, weakening this field and, at the same time, brings the clutch over gently into contact; the last move, to No. 11 contact, which is made immediately, causes the insulated bridge-piece to short-circuit the polyphase generator field. It will be observed that the exciter then only supplies current to the magnetic clutch winding, which grips solid, and the direct drive on top speed, from engine to back axle, is obtained, the generator and motor being out of action.

"AUTOGENOUS" WELDING PLANT OPENED.

The Worcester Pressed Steel Company, Worcester, Mass., manufacturers of pressed steel parts for automobiles and similar work, have just installed a plant for autogenous welding with the oxy-acetylene blow pipe flame. This is the only plant of its kind in Worcester, and but the second to be put in operation in this country. The value of such a plant lies in the fact that the oxy-acetylene flame is the hottest known, reaching a temperature of 6,300 F. or 2,700 degrees higher than that attainable with the oxy-hydrogen blow pipe. The gases are used in equal parts at a pressure varying from 15 to 150 pounds to the square inch. The process will be employed in place of riveting and soldering, tank making and other forms of construction hitherto found too difficult with the means available. It will also be used for cutting steel, as with the plow pipe the operator will be able to do work impossible with the saw.

FIRST PNEUMATIC TIRE EXPERIMENTS WERE INTERESTING.

It is curious that the man who first produced a pneumatic tire should have had no connection with the rubber industry, the bicycle trade, or even with any branch of mechanics. J. B. Dunlop was, indeed, a veterinary surgeon practising in Belfast, Ireland. He had at various times given some thought to a new wheel which would reduce vibration, but never put any of his theories into practical form. Towards the end of 1887 the idea came to him of fixing an air cushion around the rim of a wheel, and he mentioned the scheme to his son, who then rode a solid-tired tricycle. The boy, who had experienced the nerve-racking sensation of riding over roughly paved roads and was also anxious to ride faster than his companions, urged his father to experiment the new idea. Dunlop procured a disk of wood about 16 inches in diameter and one and one-half inches thick. He constructed an air tube out of the purest stock sheet rubber one-thirty-second of an inch thick, and inserted in the tube, for the purpose of inflation, a short piece of rubber tubing commonly in use for children's teething bottles, placed the air tube on the periphery of the disk of wood, covered the air tube with a strip of thin linen cloth, and secured the cloth in a temporary manner to the disk of wood by means of small tacks. The tire was inflated by means of a football pump and the tube fastened by means of a piece of thread.

One evening in December, 1887, when the yard gates had been closed the first experiment was made in the presence of Dunlop, his son, an assistant, and a friend who was interested in cycling. First a large solid-tired wheel was thrown towards the gate,

but it did not run the whole length of the yard. The small pneumatic-tire disk was thrown in the same manner. On the first attempt the disk struck the side of the wall; on the second attempt, however, it ran the whole length of the yard, struck the front gate and rebounded with considerable force. Further experiments only showed the superiority of the pneumatic-tired wheel over the solid. After the rolling friction test the wheel was tested for its resiliency. When dropped to the floor from a height of about four feet it was found to rise to nearly the point from which it started. These experiments were explained to R. J. Mecredy in 1889 and about the same time were made known to the public. The first pneumatic-tired safety bicycle was designed with a view to its being ridden at a race meet on a cinder track in England, but was not finished in time for the event.

Judging from an examination of new models, the heavy high-power motorcycle, which a few years ago enjoyed much popularity, has lost favor. Everywhere the medium and light-weight machine is being more extensively adopted. In France there is a momentary boom on the motor-bicycle. Most of this type carry a single cylinder engine entirely within the frame, and when the magneto is used it is placed above the crank case and below the top stay. Other machines of this type have the engine attached by lugs to the forward down stay of the frame, immediately behind the front wheel. The space within the frame is thus left free for gasoline tank, etc.

THEORY OF BRAKE POWER AND ADHERENCE*

YOUR automobile is rolling along at twenty, thirty, or forty miles an hour. Suddenly an obstacle is seen ahead—a cow, a horse, a team leaving the fields—and you have to stop in the shortest space possible. You throw on your brakes desperately, and just avoid an accident which might have been fatal, and which certainly would have been unpleasant. When running home the probability is that you ask yourself if it is not possible to know, even roughly, what is the minimum length in which your car can be pulled up.

To this it may be replied that it is generally possible to know approximately in what length the car can be stopped if the speed of the machine is known at the moment when the maximum braking effect is applied. By maximum braking is meant blocking the wheels, for it is only when the wheels are blocked that the maximum effect is obtained, and consequently a stoppage in the minimum distance. To stop any moving body some power must be brought into action, and there must be a fulcrum. This latter is essential, and no engineer has doubted its necessity since Archimedes first showed us its value. The force is to hand in the shape of the brake lever, but the fulcrum is on the road, and the resistance of this fulcrum is limited in value to the adherence of the brake wheels to the road, or in other words, to the value of the force producing the sliding of the wheels. It is clear that the force with which an automobile can be braked cannot be superior to, though it may equal, the adherence of the brake wheels; this adherence is therefore the superior limit of the braking power. What is the value of this resistance?

The Theory of Braking Effect.

Experience alone can reply to this question, and the answer she gave us two or three years ago was that on a normal road, dry but not dusty, the adherent force of a pneumatic tired wheel was between 63 and 67 per cent. of the force with which the wheel is applied normally to the road, so that the coefficient of adherence with which a pneumatic tired wheel is resting on a given plane is equal on an average to 0.65. This is a value from 40 to 50 per cent. higher than those determined by Morin fifty years ago for metal-shod wheels.

This obtained, a knowledge of the speed of the vehicle at the moment of maximum braking effect and of the coefficient of adherence given above multiplied by the relation of the weight carried by the braking wheels to the total weight, a relation easily obtained by means of a scale, is sufficient to obtain the minimum length corresponding to a complete stop. Mechanics have shown, and experience has confirmed the demonstration, that a moving body weighing P, with a velocity V, has a quantity of work measured by the product FL of the force F by the displacement L of its point of application, and such that there is always equality between the quantities PVF and L:

$$FL = \frac{P V^2}{2 g}$$

in which g designates a constant coefficient equal to 9.81. If the force F acting on the vehicle as a brake is constant, the preceding relation gives us the length

$$L = \frac{P V^2}{2 g F}$$

of the distance necessary to obtain a complete stop. This distance will be proportionate to the square of the velocity and, for a given value of speed, will be in inverse proportion to the braking force F. It has just been shown that this force F has as its maximum limit the product Pa of the weight P of the machine

by the coefficient of adherence a = 0.65. This would thus give for L the value

$$L = \frac{V^2}{2 g a} = \frac{V^2}{2 \cdot 9.81 \cdot 0.65}$$

if all four wheels were blocked. But as only the driving wheels are braked, and as these support generally about half the weight of the vehicle, the preceding relation gives for a stopping distance

$$L = \frac{V^2}{2 \cdot 9.81 \cdot 0.325} = 0.157 V^2$$

of the double values.

It is this last formula which has been used to calculate the following table giving the minimum length of stopping, corresponding to the different speeds of the automobile.

TABLE INDICATING MINIMUM LENGTH AND TIME IN WHICH AN AUTOMOBILE CAN BE STOPPED.

SPEED PER SECOND		SPEED PER HOUR		DISTANCE		DURATION
Meters	Yards	Kilometres	Miles	Meters	Yards	Seconds
1	1.093	3.6	2.236	0.157	0.171	0.31
2	2.187	7.2	4.473	0.628	0.686	0.63
3	3.280	10.8	6.710	1.413	1.545	0.94
4	4.374	14.4	8.947	2.51	2.745	1.25
5	5.468	18	11.184	3.93	4.297	1.57
6	6.561	21.6	13.421	5.65	6.179	1.88
7	7.655	25.2	15.658	7.69	8.410	2.20
8	8.749	28.8	17.895	10.04	10.980	2.51
9	9.842	32.4	20.132	12.72	13.811	2.83
10	10.936	36	22.369	15.70	17.170	3.14
15	16.404	54	33.554	35.37	38.683	4.71
20	21.872	72	44.739	50.80	55.558	6.28
25	27.340	90	55.924	68.125	73.886	7.85
30	32.808	108	67.109	94.130	102.516	9.42

The duration T of this distance, easily calculated by the known relation

$$F T = \frac{P V}{g}$$

existing between a propulsion F T produced by a constant force F acting during time T on a moving body weighing P, to which it communicates or reduces to zero the speed V. In the present case we have T for the duration of the stopping distance.

$$T = \frac{V}{g \cdot a} = \frac{V}{9.81 \cdot 0.325} = 0.314 V$$

To sum up, if the distance corresponding to the complete stoppage of the automobile is proportionate to the square of the speed of the vehicle, on the other hand its duration is simply proportionate to this speed. To be absolutely correct we ought to have taken into account atmospheric resistance, which naturally tends to reduce the length of the stopping distance; but this has not been done because calculation has shown that its action was felt at the commencement of the braking effect, and would only very slightly modify the results of the preceding table in the practical limits in which we have considered the question.

AUTOMOBILES IN POLAR EXPEDITIONS.

The automobile will play an important part in scientific expeditions to the Polar regions this year. Walter Wellman, who is now fitting out in Paris for a dash to the North Pole, has had a special automobile constructed at the De Bion Bouton factory, to be used in the final dash to the pole. The British expedition to the South Pole under the command of E. H. Shackleton, who was third lieutenant on the *Discovery* on its expedition to the Antarctic, will also be supplied with an automobile specially designed for ice travel.

*By René Arnoux, Vice-president Technical Commission A. C. of France. Translated from *Omnia*, by W. F. Bradley.

USE OF ALCOHOL AND GASOLINE IN FARM ENGINES*

By CHARLES EDWARD LUCKE, M.S., Ph.D., AND S. M. WOODWARD, M.S., M.A.

THE determination of the position of the alcohol engine today involves a forecast of the future, and should it be shown to be able to compete now it must inevitably reach a stronger and more important industrial position as time goes on. This is the fact that has led governments to take up the question, and among them the United States is the latest. Exploding engines operating on crude oil will average about 25,000 heat units per brake horsepower hour, which is equivalent to about 10 per cent. thermal efficiency; engines using gasoline should operate at a thermal efficiency of about 19 per cent. under similar operating conditions.

The efficiency of an alcohol engine may be assumed at this time to be unknown, but as alcohol can be burned in engines designed for gasoline, it may be assumed that such an engine will have with alcohol fuel the same thermal efficiency as with gasoline.

MEITZ & WEISS KEROSENE VAPORIZER.

The first serious attempt to examine into the possibility of alcohol as a fuel in competition with petroleum seems to have been made in 1894 in Leipzig, Germany, by Professor Hartman. The engine used was built to operate on kerosene, and used 425 grams of kerosene per hour per brake horsepower, which is equivalent to 0.935 pounds, or 1.1 pints, approximately. This indicates for kerosene a thermal efficiency of 13.6 per cent. When operating on alcohol the engine used about twice as much, or 839 grams, which with this kind of alcohol was equivalent to a thermal efficiency of 12.2 per cent., or a little less than with kerosene. This experiment would seem to indicate that, compared with kerosene, alcohol, as a fuel, offered very little chance for successful competition. In spite of this, investigations were continued and the results of this development may be summed up by stating that the thermal efficiency has been raised to something over 30 per cent.—quite a remarkable showing, in comparison with the original figure. This indicates that with a motor specially constructed for alcohol, the price per gallon might be twice as much for the latter as for petroleum, and still produce power for less money, assuming all other conditions, such as cost of attendance, lubrication, etc., being the same.

Results of Government Tests.

The Office of Experiment Stations of this Department, in connection with its Irrigation and Drainage Investigations, has tested a number of different types of gasoline engines with alcohol and obtained figures which show the comparative consumption of gasoline and alcohol in the same engine. The first tests were made without any particular attempt at obtaining the best adjustment of the engine for each fuel, and showed a consumption of alcohol two to three times as great by weight per horsepower hour as was necessary with gasoline or kerosene. These figures indicate the necessity or desirability of determining the proper conditions of adjustment, because these were found to have a serious influence on the amount of fuel consumed. With care in adjusting the engine so as to secure the most

economical use of the alcohol, it was found that, under like conditions, a small engine consumed 1.23 pounds of alcohol to 0.69 pound of gasoline per brake horsepower hour—that is, with the best adjustment of the engine for each fuel there was required 1.8 times as much alcohol by weight as gasoline per brake horsepower hour. It was also shown in making this adjustment that it was possible to burn more than twice as much alcohol as stated, by improper adjustments, and still have the engine working in an apparently satisfactory way. The range of excess gasoline which might be burned without interfering seriously with the working of the engine was not so great, being a little less than twice as much as the minimum.

Special Vaporizers Employed.

There is on the American market a class of engines having a vaporizer which forms part of the cylinder head and which is heated by the explosions taking place inside the exploding chamber. One of these is shown in Fig. 7. On this figure, A is the vaporizer proper. Under it is seen a lamp (B), the burner and vaporizer being surrounded by a casing (D). This vaporizer is bolted to the cylinder head (E), and contains on its inner end a lip projecting into the exploding chamber. A little pump injects a small stream of oil at every stroke and drops it on this lip from the pipe (F). This lip is very hot from previous explosions and from the lamp, which is turned off when the engine begins work. The compression stroke forces the air in the cylinder over the lip and through the neck into the vaporizer bulb, thus mixing more or less completely the vapor which forms on the lip with the air that is forced over the lip into the bulb. Such hot-bulb vaporizers as this will work with practically all of the fuels—crude oils, gasoline, kerosene, and alcohol—with proper adjustments of the pump and of the temperature of the receiving bulb.

Another vaporizer of a similar order, but designed especially for alcohol, illustrated in Fig. 8, is known as the Brouhot, a French type. Exhaust gas enters at the bottom, as shown by the arrow and lettering on the cut, and rises through the iron chamber, which is corrugated to increase the surface. Alcohol is admitted near the bottom of these ribs, and flows upward on the side opposite to that heated by the exhaust gases. The regulating valve is attached to permit some exhaust gases to pass around the heating chamber and so vary its temperature, but the regulation must be done by hand. Vapor rising from the surface of the alcohol in the top of the chamber meets air, which passes first through the regulating valve intended for the adjustment of proportions. The corrugations are such as to form a screw thread or a helix passage, and the exhaust entering first at the bottom, passes directly to the top of the chamber and downward in the helical groove to the bottom, so that the top of the helix will be the hottest part. Alcohol enters the bottom of the opposite helix, flows upward and vaporizes somewhere in its upward course, discharging into the air current at the hot top of the helix as superheated alcohol vapor. This vaporizer is,

BROUHOT ALCOHOL VAPORIZER.

*Extract from Bulletin No. 277, U. S. Department of Agriculture.

therefore, of the boiling type, but the boiling takes place on the surface of the liquid which is at the pressure in the suction pipe, and the rate of boiling is regulated by hand by admitting more or less exhaust gases to the vaporizing helix.

Separate vaporizers as distinguished from carbureters are essential for kerosene and common for alcohol. They have been described at this point because the principles of their operation are simpler than those of carbureters, and they are less numerous and less representative. Carburetion is a process distinctly different from boiling. Air may take up the vapor of a liquid just as it takes up the vapor of water, even when the temperature of the liquid or the temperature of the air is very considerably less than the boiling point of the liquid. * * *

Conclusions.

The following conclusions regarding the use of alcohol as fuel for engines as compared with gasoline are based on the preliminary results of the Department's experiments, upon results of the European experiments and investigations which have been presented in the foregoing pages, and upon the general knowledge of the authors:

- (1) Any engine on the American market to-day, operating with gasoline or kerosene, can operate with alcohol fuel without any structural change whatever with proper manipulation.
- (2) Alcohol contains approximately 0.6 of the heating value of gasoline, by weight, and in the Department's experiments a small engine required 1.8 times as much alcohol as gasoline per horsepower hour. This corresponds very closely with the relative heating value of the fuels, indicating practically the same thermal efficiency with the two when vaporization is complete.
- (3) In some cases carbureters designed for gasoline do not vaporize all the alcohol supplied, and in such cases the excess of alcohol consumed is greater than indicated above.
- (4) The absolute excess of alcohol consumed over gasoline or kerosene will be reduced by such changes as will increase the thermal efficiency of the engine.
- (5) The thermal efficiency of these engines can be improved when they are to be operated by alcohol, first by altering the con-

struction of the carbureter to accomplish complete vaporization, and, second, by increasing the compression very materially.

(6) An engine designed for gasoline or kerosene can, without any material alterations to adapt it to alcohol, give slightly more power (about 10 per cent.) than when operated with gasoline or kerosene, but this increase is at the expense of greater consumption of fuel. By alterations designed to adapt the engine to new fuel, this excess of power may be increased to about 20 per cent.

(7) Because of the increased output without corresponding increase in size, alcohol engines should sell for less per horsepower than gasoline or kerosene engines of the same class.

(8) The different designs of gasoline or kerosene engines are not equally well adapted to the burning of alcohol, though all may burn it with a fair degree of success.

(9) Storage of alcohol and its use in engines is much less dangerous than that of gasoline.

(10) The exhaust from an alcohol engine is less likely to be offensive, although there will be some odor, due to lubricating oil and imperfect combustion, if the engine is not skillfully operated.

(11) It requires no more skill to operate an alcohol engine than one intended for gasoline or kerosene.

(12) There is no reason to suppose that the cost of repairs and lubrication will be any greater for an alcohol engine.

(13) There seems to be no tendency for the interior of an alcohol engine to become sooty.

(14) With proper manipulation, there seems to be no undue corrosion of the interior due to the use of alcohol.

(15) The fact that the exhaust from the alcohol engine is not as hot as that from gasoline and kerosene engines seems to indicate that there will be less danger from fire and less possibility of burning the lubricating oil. This is also borne out by the fact that the exhaust shows less smokiness.

(16) In localities where there is a supply of cheap raw material for the manufacture of denatured alcohol, and which are remote from the source of supply of gasoline, alcohol may immediately compete with gasoline as a fuel for engines.

(17) If, as time goes on, kerosene and its distillates become scarcer and dearer, the alcohol engine will become a stronger and stronger competitor, with a possibility that in time it may entirely supplant the kerosene and gasoline engines.

(18) By reason of its greater safety and its adaptability to the work, alcohol should immediately supplant gasoline for use in boats.

(19) By reason of cleanliness in handling the fuel, and increased safety in fuel storage, alcohol engines will, in part, displace gasoline engines for automobile work, but only when cost of fuel is a subordinate consideration. In this field it is impossible to conveniently increase the compression because of starting difficulties, so that the efficiency cannot be improved as conveniently as in other types of engines.

(20) In most localities it is unlikely that alcohol power will be cheaper or as cheap as gasoline power for some time to come.

SERVICE TEST OF A FINISHED CADILLAC CAR IN THE SNOW-CLAD MICHIGAN WOODS.

The thermometer was at zero, and the road, or path, had not been traveled in weeks. The machine, a four-cylinder Model G, had to make its way through a heavy snow on the level and great drifts in places. No chain grips were used, the car going satisfactorily without.

LETTERS INTERESTING AND INSTRUCTIVE

Correcting a Faulty Steering Gear.

Editor THE AUTOMOBILE:

[611.]—Will you please answer the following through your valuable journal:

(1) I have a touring car which has a defective steering gear. It is of the irreversible design (worm and segment), and will only turn the front wheels half as far one way as the other. They will turn to the left all right, but will only turn to the right a very small distance. The car came to me new this way. I can see only one way to remedy it, and that is to bend the arm on the steering knuckle where the connecting rod from the segment arm fastens. Can you give me an idea as to how I can adjust it, as it makes steering very inconvenient?

(2) What damage would be done to the coil if too large a current is supplied to it? How many dry cells would you recommend for the best results?

(3) When one's home city does not require an owner to carry a number on his car, what requirements would it be necessary for him to follow if he should wish to operate his car or pass through some city which requires registration? A SUBSCRIBER.
Ankenytown, O.

Such a state of affairs as you describe in the first part of your letter would appear to constitute a strange oversight on the part of the factory that shipped you the car. It would appear that in assembling the steering gear, the segment was left much too far one way or the other from the center of its travel on the worm, so that as you say it has more than sufficient movement in one direction but not enough in the other. Such a car would be very dangerous to drive, and if just received new, probably the best thing to do would be to advise the maker and have him correct it. If you wish to remedy it yourself, disconnect the steering gear and take it down. See if there is anything else wrong with it other than that indicated above, and if not, turn the wheel until the segment is exactly at the center of its range of travel on the worm; that is, so that moving the wheel one way or the other will cause the same amount of movement at the lever in either direction. It may be found on dismantling the gear that something has become deranged, and that the trouble is not due to faulty assembling, but if such is not the case, centering the segment on the worm, and then after accurately centering the front wheels, reconnecting in that position, should remedy the difficulty. We should not recommend such a makeshift as bending the arm on the steering knuckle.

(2) The insulation of the secondary is apt to be broken down, either partly or wholly, by the discharge breaking through the insulation and jumping from layer to layer, thus greatly reducing or totally destroying its efficiency.

(3) It will be necessary to register in accordance with the law of the State which you wish to enter; cities in the same State very seldom have local enactments in force regarding registration, but where such is the case, it would probably also be necessary to register in such city.

Percentage of Heat Losses in Air-Cooled Motors.

Editor THE AUTOMOBILE:

[612.]—I wish to thank you for your answer to my proposition submitted some time ago concerning the relative power of an air and water-cooled motor of the same size, though I have as yet been unable to convince my friend who held the other end of the argument that I am right. If there is any accurate means of ascertaining exactly the percentage of the heat losses in engines of the air-cooled type, and this can be done, would an article on the subject be available for publication in the columns of "The Automobile"?
SIDNEY BARRETT.

Carteret, N. J.

If you have made any scientific tests with a view to determining the exact percentage of heat losses in air-cooled motors, we would be pleased to have you submit an article setting forth the nature of your experiments as well as the data resulting therefrom. After seeing it we can tell you whether it will be available for publication in the columns of THE AUTOMOBILE or not.

Information Asked on Many Points.

Editor THE AUTOMOBILE:

[613.]—Will you kindly answer the following questions under the head of Letters Interesting and Instructive and oblige.

(1) An automobile owned in a State which has no registration or license law is used temporarily by its owner in another State which does have a registration or license law. Is it subject to the automobile law of such last-named State? How is it, suppose the visiting car is used in the latter State merely on a continuous journey from one to or through the other?

(2) So long as a machine will actually climb a given grade on the high gears, is there any disadvantage to the machine in using them, instead of lower ones?

(3) Scientifically, how much more resilient is a pneumatic tire, with as small an air-space as those which use the heaviest fabric and rubber, than a solid rubber tire? If two solids and two pneumatics were to be used on a touring car, where should they properly be put to get the best results?

(4) Owners seem to be recommended on all hands to use large tires. Is there not an actual limit to the size of tire that can be used advantageously on a given rim? If so, what is the limit? Assume a standard clincher rim 2 1-2 inches wide, and what is the largest tire that can properly be used on it?

(5) In comparing the resiliency of solid and pneumatic tires, what is your opinion as to the difference between unaided pneumatics and solids used with a standard shock-absorber?

Cambridge, O.

GREENHORN.

(1) In the majority of States which have passed legislation on the subject, excepting those which go to radical and unreasonable extremes, such as New Jersey and Pennsylvania, non-resident owners of cars are exempted from the provisions of the statute, either altogether, as in New York, or for a limited period; as, for instance, 48 hours in Delaware and 15 days in Connecticut. But in practically every case, this exemption is conditioned upon such non-resident having complied with the laws of his home State in this regard, which means that he must display the registration number taken out there. A statute that has probably served as a model for the majority in this respect is that of New York, subdivision 9 of which reads as follows: "The provisions of this section (regarding registration and display of number) shall not apply to motor vehicles owned by non-residents of this State, provided the owners thereof have complied with any law requiring the registration of owners of motor vehicles in force in the State, etc., of their residence, and the registration number showing the initial of such State shall be displayed on such vehicle substantially as in this section provided." Michigan makes this exemption depend upon the granting of similar privileges by the State from which such non-resident hails, so that an autoist from Jersey or Pennsylvania could not travel in Michigan without registering in the latter. Though not explicitly so stated, the inference is unavoidable that an autoist hailing from a State having no legislation on the subject, would be compelled to register in the first State he entered that had such a law, and that such registration would then serve him in every other State except such as ignored the demands of comity.

(2) The mere fact that a car can be nursed or forced over a grade on the high-gear is far from constituting a reason why this should be done. The chief object of the provision of various ratios of gearing is to enable the motor to be run as nearly as possible at the speed at which it develops its maximum torque, and a skillful driver will shift gears as frequently as it is necessary to maintain this. By permitting the motor to labor and thump, many a car can drag itself over comparatively steep hills on the high gear, but it is absolutely injurious to the motor to treat it in such fashion, and shows little or no knowledge of the elements of either mechanics or driving. Gears should be shifted as soon as the motor slows down unduly, not waiting until it is about to gasp its last and then racing it as is so frequently done.

(3) So far as we know, while there is no data extant regarding the first part of your third question, there can be no com-

parison between any solid rubber tire and the heaviest pneumatics, as the air space is always proportionate to the size, regardless of the weight of the fabric or rubber. Reducing the air space would, of course, have the effect of reducing the resiliency of the tire. In using tires of both types on the same car, the solids would be put on the driving wheels.

(4) Rim sizes increase proportionately with tire sizes, and one must be adapted to the other in order to be used advantageously. For instance, the smallest tires made, which are 26 by 2 1-2 inches, take a rim 1 3-8 inches wide; a 4-inch tire takes a 2-inch rim; a 4 1-2-inch tire a 2 1-4-inch rim, so that the size tire that would give best service on a 2 1-2-inch rim would be a 5-inch. It is axiomatic that the larger the tire, the greater must be the size of its retaining beads (clincher type), and the rim must be enlarged correspondingly to accommodate them. In consequence, there is always a limit to the size of tire that can be used advantageously on a given rim, but there is nothing to prevent increasing the size of the rim. This subject was gone into at length in THE AUTOMOBILE of August 9, 1906, pp. 169-173.

(5) Concerning your last question, we should say that the unaided pneumatics would be superior to solid tires with shock absorbers, the office of the latter being more as an aid to the springs than to the tires. The limit of the resiliency of the solid tire is reached in absorbing what has been euphroniously christened "dither"; that is, vibration. Between this and the hard jolts which the shock-absorber is designed to take care of, there is a vast amount of bumping and jolting that only the pneumatic tire can efficiently cope with.

Why There Is No Danger from Backfire.

Editor THE AUTOMOBILE:

[614.]—I notice in the issue of "The Automobile" of February 21, under the head of "Letters Interesting and Instructive," letter No. 582, a question was asked reading as follows:

"We have had trouble from flashes of fire coming from the carbureter when the motor is running."

Will you kindly let me know through your columns how it is that fire can flash from a carbureter without causing a serious explosion of the mixture, and oblige a three-years' reader of your paper.

New York City.

J. E. R. H.

The reason for the non-occurrence of either an explosion or the ignition of the contents of the float chamber of the carbureter, when by reason of a back fire through the carbureter flame is seen to issue from it, is due to the fact that there is nothing to support combustion there. Any mixture that might be in the body of the carbureter itself would be entirely too rich to explode, while the float chamber would, in all probability, be filled with almost pure gasoline vapor, and the latter cannot burn without oxygen. About the only point at which ignition would be apt to take place would be at the spray nozzle, of the spraying gasoline as it issued, and while there would probably be sufficient oxygen at that point to maintain a flame in a quiescent state, with the motor running, the suction would doubtless be so strong as to blow it out every time.

Why Is the Two-cycle Motor Not More Popular?

Editor THE AUTOMOBILE:

[615.]—What is the two-cycle motor? Is it practical for automobile uses? I see one concern manufactures it, and if it's such a good thing, why don't some of the hundreds of other manufacturers in Europe and America make it?

INQUIRER.

Oil City, Pa.

The two-cycle, or more properly speaking, the two-part cycle motor, is a type in which, as its name indicates, there are but two parts to the cycle, so that there is an impulse given the piston every revolution, instead of every other revolution, as in the four-cycle. The induction and compression strokes of the four-cycle motor are combined in one, as are also the firing and exhaust strokes. To accomplish this the mixture is drawn into the crankcase, made airtight for the purpose, and delivered to the compression chamber of the cylinder through a bypass and

port opened by the piston itself; another port, similarly operated, permitting the escape of the exhaust. For a more detailed explanation of the two-cycle motor we would refer you to the articles that have been published in the columns of THE AUTOMOBILE during the past year. While there is but one firm that builds automobiles with two-cycle motors in this country, there are probably a score or more who have been building two-cycle marine motors for quite a few years, and their output is large. The fact that the firm in question has been building cars successfully for the past six years or more would appear to answer your query regarding its use on the automobile, in the affirmative. There are also one or two firms on the other side who have built two-cycle automobile motors, but not to any extent. Probably the chief reason why more have not taken it up is because they do not regard it as having yet reached a stage where it can compete with the four-cycle, though a discussion of the various pros and cons is not possible here.

Many Readers Quick to Detect Error.

Editor THE AUTOMOBILE:

[616.]—I would like to ask what proof you can offer of the statement made in answer to question No. 585 that a vertical line represents a 45 per cent. grade?

H. L. HORNING.

Waukesha, Wis.

Editor THE AUTOMOBILE:

[616A.]—On page 356 of your current number, in reply to letter No. 585, you say: "Bearing in mind the fact that a 45 per cent. grade" "represents a vertical line." Is this correct? Isn't a 100 per cent. grade exactly 45 degrees, and doesn't infinity per cent. grade represent a vertical line? I am of the impression that the steepest place in Eagle Rock Hill is about 17 per cent., and in Jacob's Ladder about 20 per cent.

"GASOLINE SAL."

New York City.

Editor THE AUTOMOBILE:

[617.]—Referring to your answer to inquiry No. 585, I should be pleased to know how you arrive at the conclusion that a "45 per cent. grade represents a vertical line." We have always supposed that the number of feet rise per 100 feet horizontal distance gives the per cent. of a grade. That is, a 100 per cent. grade makes an angle of 45 degrees with the horizontal. Is this understanding correct?

H. H. F.

Galion, O.

Editor THE AUTOMOBILE:

[618.]—I wish to correct a statement which you made in your answer to letter No. 585, issue of February 21. You say: "Bearing in mind the fact that a 45 per cent. grade is represented by a vertical line." This must have been a mistake, for a little further on in the same article you say a grade of 1 in 9 equals 10 per cent. or 11 per cent. nearly; following out this line of reasoning we come to a rise of 1 foot in 1 foot making 100 per cent. grade, and also makes an angle of 45 degrees with the horizontal. A vertical line represents a grade which is infinite, but is 90 per cent. to the horizontal. I have seen automobiles climb a 40 per cent. grade on smooth wooden boards for the grade, Jacob's Ladder, of which you speak, has an average grade of 25 per cent., but has a maximum of 31 per cent., which is quite a little in excess of your figures.

This subject of grades in per cents. and degrees seems to be pretty poorly understood by the automobile public, as well as the trade, and I would suggest your publishing in the near future the rough rules for computing the different gradients.

West Medford, Mass.

EVERETT H. SHEPARD.

Editor THE AUTOMOBILE:

[619.]—Are you not mixed up in your statements about grades in your answer to question No. 585, issue of February 21? How can a 45 per cent. grade represent a vertical line? In steam railroad practice the grade of the track is usually described in feet per mile, but in street railroad practice, where much steeper grades are used, it is usually described in feet per hundred, or, what is the same thing, by a percentage. For instance, if a stretch of track 100 feet long is 2 feet higher at one end than at the other, its grade is called a 2 per cent. grade; and, in the same way, if the track rises 10 feet in running a distance of 100 feet, it would be a 10 per cent. grade. Now, on the above basis, a 50 per cent. grade would only be about one-quarter of the way to the vertical, a 100 per cent. grade just half way, and, if I remember my trigonometry, the grade percentage of a vertical line would be infinity.

I thought at first you might have confused the angle of the rise from the horizontal with the percentage of grade, but you evidently have not, for a 45 per cent. angle is only half way to the vertical, a right angle being 90 degrees, of course. I think I have

seen photographs of automobiles climbing wooden inclined planes at an angle of 45 degrees, and I am sure that when I took my runabout up an inclined plane to the second story of a paint shop the other day, we went up a grade that was at least 25 per cent., with plenty of power to spare.

If there is any misunderstanding as to what the percentage of a grade means, I think it important that you should have an article in your valuable paper on the subject.

Hartford, Conn.

ARTHUR PERKINS.

The statement regarding grade percentages and the manner in which they are figured, to which the foregoing correspondents take exception, was an inadvertent error that was so palpably wrong that it is little wonder it has attracted so much attention. It should have been stated, of course, that a 45 degree angle represented a 100 per cent. grade, as was explained in the following issue of THE AUTOMOBILE. It is gratifying to note, however, how closely the inquiries and answers to correspondents are followed, as the paper scarcely had time to be in the hands of subscribers before letters were received taking exception to the above.

How to Find Horsepower Ratings.

Editor THE AUTOMOBILE:

[620.]—Will you kindly advise me how to find the power of two, four and six-cylinder automobile engines, and also what is the reason for the varying rating in the case of different makes. For example, take the Rambler four-cylinder car; it has a larger cylinder than the Maxwell four-cylinder, but a smaller power rating, namely 35 horsepower.

GEORGE W. BARLOW.

Mahanoy City, Pa.

There is an endless number of formulæ for ascertaining the power of an engine, but there is no good reason to believe that any of them have superseded the old standard used for so many years in calculating the power of steam engines. This is expressed

$$\text{Horsepower} = \frac{P L A N}{33,000}$$

in which P equals the mean effective pressure throughout the working stroke in pounds per square inch, L the travel of the piston in linear feet, and A the area of the piston in square inches, while N represents the number of working strokes per minute. The only difference between this and the same formula as used for the steam engine is in the equivalent of N, which represents revolutions per minute in the latter case. From this you will see that there are a number of factors beside the size of the cylinder upon which the horsepower of the motor depends. The horsepower of a multicylinder motor may be ascertained most readily by finding the output of one cylinder and multiplying by the number used. It must be borne in mind that the mean effective pressure referred to does not mean the compression, though the latter, of course, has a strong bearing on it. It means the average pressure in pounds per square inch exerted on the head of the piston from the moment of ignition to the end of the stroke, and is generally calculated with the aid of a planimeter from indicator cards of the engine tested.

Engines Run by Inflammable Dust.

Editor THE AUTOMOBILE:

[621.]—In a foreign periodical I read the other day a reference to some experimental engine that was said to burn coal dust. No details of construction were given, and I am interested to know something of them. Is anything of the kind really practical, and just how does it work? I understand that the dust is burned inside of the cylinder, as is the case with the fuel of any internal-combustion engine.

F. W. WALLACE.

Temple, Tex.

In Germany, a good deal of experimental and development work has been done along the line you suggest, and it is perhaps quite within the bounds of possibility that at some time in the future dust engines may be developed to a high degree of efficiency and serviceability. All there is to the idea is that of making an explosive mixture of air and of some impalpable fuel dust. It has long been known that such mixtures explode upon ignition. If there were any doubt upon this score,

the common occurrence of dust explosions in coal mines and in flour and cotton mills would be conclusive. Apparently, any substance capable of being burned in the air will, if reduced to small enough particles and diffused throughout a mass of air, undergo upon ignition a rapid combustion that is practically explosive in character. Probably certain proportions of mixture are required, as in the case of liquid and gaseous fuels, but the only other conditions to be observed are those of having the diffusion equal and the fuel particles small enough. For a few cents you can buy at any drug store a quantity of lycopodium powder—the resinous spores of a sort of moss-like plant—which will flash like powder if thrown into the air and lit with a match, illustrating the principle involved in a very interesting manner. Of course, in making a really reliable engine to operate on this principle, there are a number of serious difficulties in the way. The abrasive effect of the fuel or its ashes is likely to cause serious scoring of cylinder walls, unless kept off or quickly removed from them, while the problem of infallibly securing properly-measured and compounded fuel charges is one that might well make the present-day carburetor problem seem simple. The best results so far secured have been with vertical two-cycle engines, which possess the double advantage of keeping the fuel away from the walls as much as possible, while at the same time running the succession of charges through in a constant direction—in such a way that there is less chance of fouling than would exist with a four-cycle construction, in which the functioning involves to-and-fro travel of the gases. Attempts also have been made to stratify the charges, surrounding a central core of combustible mixture with wall-protecting zones of air.

Why Gasoline Motors Are Not Double-Acting.

Editor THE AUTOMOBILE:

[622.]—Will you kindly advise me why gasoline motors do not take their power from both ends of cylinder, same as steam engines; and why can they not be built the same as steam engines?

BURTON D. GIBBS.

North Blandford, Mass.

Editor THE AUTOMOBILE:

[623.]—In the building of gasoline engines why are not the cylinders made in the same way as on the steam engine? That is, why is the impulse or active stroke confined to one side of the piston? Why should gas not be admitted on both sides of the piston so as to drive in both directions, as is done in the case of the steam engine?

W. M. GEORGE.

Dexter, O.

The chief reason for not building gasoline engines of the double-acting type, as is done in the case of the steam engine, arises from the necessity of cooling the piston and piston rod and the attendant complication, when an explosion occurs on each side of the piston. It is not at all unusual to build double-acting gas engines, but their use is confined to stationary units and they are usually of comparatively large powers. The Standard 300-horsepower, six-cylinder marine motor is double-acting, as is the Nurnberg engine, a stationary type having two double-acting cylinders placed tandem.

A Doubtful Way of Improving a Car.

Editor THE AUTOMOBILE:

[624.]—I have a 1905 four-cylinder Autocar, and, as the tonneau is detachable, I expect to use it this season as a runabout, and my object in writing you is to find if reducing the wheelbase, which is 96 inches, to say 80 inches, by cutting off the rear end of the car and moving the rear axle forward, also cutting the driving shaft, would reduce the weight and increase the power enough to make the expense worth while?

The car is equipped with Hartford shock absorbers, so the shortening would not affect the riding qualities very much, and I would also remove a leaf from the rear springs.

Kindly let me know your ideas on the above.

New York City.

RICHARD A. STREIT.

The changes you mention in your letter would undoubtedly lighten the car considerably, but whether they would be beneficial or not is quite another matter. Regardless of how much you shorten the car and its wheelbase, the power will not be in-

creased, though we presume, by this statement, you mean that the horsepower with regard to the weight will be greater than previously. If the car is not greatly underpowered, the removal of the tonneau alone should prove sufficient to make it as powerful and speedy as a car of its size can reasonably be expected to be. A wheelbase of 96 inches is not excessive for a runabout, and the work and expense involved in reducing it a matter of 16 inches would be a doubtful investment. We certainly should not recommend it on the score of improving the running or riding qualities of the car. If the rear springs prove too stiff, the expedient of removing a leaf might be tried, but it would be better to leave them as they are until experience has shown the necessity of a change. Making the alterations mentioned would also prevent ever using the chassis with the touring body again.

A Difficult Problem.

Editor THE AUTOMOBILE:

[625.]—Will you kindly tell me, through the columns of your paper, how much compression I want, how fast should I run my engine to get good results, and what size sprockets do I need? I have a single-cylinder, 4 3/4" x 6" planetary transmission, 28-inch wheels. The car weighs about 1,500 pounds.

Andover, Ohio.

MYRLE SARGENT.

It is absolutely impossible for us to give an intelligent answer to your question, with the meager data you give as a line upon your requirements. You do not even say how fast you expect the car to run, which makes it utterly out of the question for anyone to attempt to supply satisfactory information concerning sprocket sizes, compression, etc. Upon receipt of fuller particulars we will be pleased to give you the desired information.

SUGGESTIONS FOR A PUZZLED SUBSCRIBER.

Editor THE AUTOMOBILE:

[626.]—An inquiry in your issue of January 10 has been called to my attention, and, as it is of an unusual character and it is possible that the right answer is still to come, I take the liberty of offering a suggestion at this late date. The item is headed "An Easy One, and Then a Hard One" (529), and is signed "A Subscriber," Bayside, N. Y.

Inquirer's motor is certainly behaving very queerly, and few "experts" would venture to say for sure why it works intermittently. The writer hopes, however, to at least start a line of investigation that will locate the guilty apparatus. I should first make sure the exhaust valves are not "hung up" to some extent, when a certain temperature is reached in each cylinder—one after the other quitting and staying out till temperature comes down.

Next, see that ignition spark mechanism is not so near its limit as to fail to spark inside of cylinder, as one by one their temperature and resistance become greater—such action as described being far more likely to occur in make-and-break ignition than with jump-spark. With former system the contacts are liable to stick and fail to operate at high temperature. With jump-spark the intervals of inaction would be very short, as internal temperature would fall rapidly after miss-firing. These details being found in order, I should then investigate the carbureter, and undertake to find out if the continuous, wide-open suction draws an excess of fuel into air passages, and eventually causes the miss-firing, cylinders quitting in the order of least ignition efficiency. The laying down of some cylinders of course results in a slow-down, and reduced fuel supply ratio, which soon restores the mixture, and allows other cylinders to resume operations.

It is likely that "Subscriber" will be able to readily prove out the suggestions above, but we will be pleased to suggest means of doing so if he makes written inquiry of us direct. We hope he finds the correct solution of the problem, and will appreciate the favor if he mails us a postal card informing us of the same.

THE R. E. HARDY CO.

New York City.

By F. J. Watt.

PISTON VALVES STILL A PERTINENT TOPIC.

Editor THE AUTOMOBILE:

[627.]—In answer to Mr. Malcolm's reply to my letter, I always thought Mr. Malcolm to be deeply interested in the development of the two-cycle engine, and a man who has had considerable experience. But it is clearly seen by his prejudice against the piston valve that his experience in this line has been very limited, or conducted on a wrong principle. I think Mr. Malcolm would be able to see the advantage of this particular construction if

he was not so influenced by his prejudice against the piston valve, and would probably think it worth while to start a discussion on the matter if his knowledge on the subject were a little broader. I would like very much to know if he ever constructed a two-cycle engine of any design that would throttle or run as slow as 100 revolutions per minute without missing. If so, where can it be seen in operation? Mr. Malcolm states that the only excuse for using the piston valve is for the purpose of locating it in a place of small cubic capacity in order to retain and keep the charge separated from the burned gases when the engine is throttled and running light. He also states that my construction will not permit of this. Now, where does he get his authority for making such a statement when he has seen neither one of my engines nor a working drawing? I would like to inform him that this is only one of my reasons for using check valves, and if he will give the principle a little study he will find several other advantages that cannot be accomplished in any other design.

These statements made by Mr. Malcolm are purely theoretical. Now for the actual facts from experience on my part. If the results mentioned by Mr. Malcolm as "being impossible in my engine" are not obtained in an engine that will throttle to 100 revolutions per minute running empty and slower when loaded, then they are not beneficial. I now have in operation, where anyone may see it, a four-cylinder two-cycle motor, built on the principle shown in my first article. Cylinder, 4-inch bore 3 1/2-inch stroke. Weight of complete engine, 200 pounds (no attempt being made at extreme lightness). Weight of flywheel, 25 pounds. This engine will throttle down to 100 revolutions per minute, empty, and continue to run at this speed any length of time without missing an explosion. It will respond instantly on opening the throttle. It will run as fast as 2,500 revolutions per minute without missing. This certainly contradicts Mr. Malcolm's statement that the valve would refuse to lift if engine were running very fast. This engine develops 30-horsepower at 1,200 revolutions per minute by Prony brake test.

Mr. Malcolm makes some very erratic statements in his letter replying to Mr. Miller. He says that the two-cycle engine has no positive means of introducing the fresh gas or expelling the burned gases. Now, if he will forget his prejudice long enough to give my sketch a little study, he will see that the charge is introduced just as positively as in a four-cycle engine, or more so if there is any difference. Now these gases being positively introduced will just as positively drive out the burned gases before it, and do it with less loss (and less mixing of the fresh gas with the burned), than in any engine introducing the fresh charge through ports and depending on the deflector to separate it from the burned. Mr. Malcolm's statements in his various articles as to the reliability of the two-cycle engine would be very conflicting to a person not having actual experience with these engines. What we want are actual facts.

At the end of my criticism of Mr. Malcolm's article he states through an editor's note that the error referred to by me was due to the draughtsman. Now, will Mr. Malcolm kindly explain how the condition so minutely described was to be obtained of having the spark plug extend down into the tube with the valve in any other position than that shown in his drawing? If he intended the valve to be in the position shown by sketch, where does the tube come in that surrounds the spark plug when the piston is at top of stroke?

L. R. WOTTRING.

Prospect, O.

TESTING TO OVERCOME PITTING OF POINTS.

Editor THE AUTOMOBILE:

[628.]—I note in the issue of February 21, letter No. 584, and would advise Mr. Stark to have his coil tested with a Connecticut Coil Ammeter, and see how much current it is taking from his battery. The pitting points to large current consumption, and in most every coil I test this is the trouble. I have a four-cylinder coil here now, two coils of which will not work at less than 1 3/4 amperes, and they should work at not over 1-2 to 3-4 of an ampere, while the coils on my cars are set at 4-10 of an ampere and never give any trouble.

E. F. BACHELLER.

Lynn, Mass.

ANOTHER TO THE RESCUE OF NO. 582.

Editor THE AUTOMOBILE:

[629.]—In reference to your reply to Wenzel Bros. & Co., No. 582, will say that in the writer's opinion the cause of motor running unsteady is due either to a clogged gasoline supply to carbureter or a sticky float, and that the back-firing in carbureter is due to the mixture becoming too weak through lack of proper gasoline level in carbureter, and not on account of improper valve timing or pitted valve seats, as you suggest. What did No. 580 find to be the cause?

W. H. RICKEY.

East Orange, N. J.

A Thousand-Mile Tour in Three States.

by A. H. Smith.

IN this particular Illinois home that evening the conversation had drifted to the ever-fascinating subject of touring—just as it so often does in thousands of other homes—and comment was made that within two years some sixty automobiles have come into use near Earlville, and that, like in other communities, as the home drives become familiar there follows the natural desire for touring. It is safe to say that no subject appeals more strongly to the average autoist to-day. Every owner of a car has unconsciously let his mind's eye wander to distant cities where reside relatives or friends at whose door he will sooner or later rap.

Following comment at home gatherings comes anticipation, and, soon, the genuine realization. Notice of our departure was so short that little opportunity was had for anticipating; in fact, our "road map" at the start was cut from a railroad time table picked up the last minute before waving handkerchiefs to friends and gliding swiftly away from Earlville, Ill., at 9:30 A. M., Wednesday, October 3, en route, as we supposed, to the State fair at Springfield, 170 miles to our southwest. We talked a little of extending the trip, but had hardly considered it seriously. However, the first day out settled it.

It was a clear October day, with rustling autumn leaves of every tint and hue, and the very atmosphere seemed to carry the

regular pulsing throb of our motor to the beautiful wooded hills and to bring back the echo of "Come, come, come," as the car reeled off the miles past the constantly changing panorama of productive Illinois farms, the world's greatest corn belt.

At 10:40, Utica, at the base of the bluff in the Illinois river valley, was passed, and the river crossed by ferry boat, there being three spans of the bridge missing since a severe wind storm last Summer, when an unfortunate farmer and his team were drowned in crossing. For three passengers and our Cadillac the modest sum of 55 cents was charged, but the teams on the same boat paid less and took up more space. Very good dirt and gravel roads were found ahead, and we stopped at Wenona for dinner. The Illinois Central Railroad was followed from here almost due south.

Kappi was reached in the middle of the afternoon. Long live Kappi, and may it prosper, for we got lost in the ravines and made ineffectual attempts to ford the Mackinaw river, that looked dark and treacherous after a recent rain. For twenty miles down stream there was no bridge, but three miles up there was one, and now for a rougher country and winding roads and pretty scenery.

Shortly after 6 o'clock Bloomington was reached, and we registered at the Illinois. Here it was learned that the Bloomington

ON THE ROAD NEAR COLUMBUS, IND., AFTER PASSING A CARAVAN OF MIGRATING GYPSIES.

CROSSING ILLINOIS RIVER BY CABLE FERRY.

club had planned a road run of seventy miles to the State fair. We met Samuel Erwin, first vice-president of the Illinois State Automobile Association, and next morning at 9 o'clock took after his Buick, from which was scattered the confetti at every turn to guide the club members. Such a morning! Cloudy, foggy, and drizzling. Two miles out Mr. Erwin turned back, as no other club members ventured, and we hit the trail alone. Later members of the club went as far as Lincoln, telephoned to Springfield, found it raining there and turned back.

We took dinner at Lincoln, thence bore west and south to Fancy Prairie, where mud began to bother and things ahead looked like anything but a "fancy prairie." A crowd of good-natured loungers at the country store, headed by a joker named "Rube," asked questions and watched while gasoline was procured for a twenty-mile pull through mud, mud, mud, to Springfield, capital of the great State of Illinois, whose inhabitants would blush for such highways could they know of the hundreds of miles of really excellent hard roads our party were to encounter in sections of country less thrifty. There was just one redeeming feature about that twenty miles of mud, and that was the way our sturdy car slowly but surely plowed through it on low gear for three hours, past horses and buggies that tried to keep up. We had been advised for thirty miles to keep away from "sand hill," but conquered it at a steady pull, arriving in Springfield at 7 o'clock. Friday and most of Saturday were pleasantly spent in viewing the State fair and city, and in visiting friends.

Fascination of Touring Had a Grip.

But the fascination of touring had a grip on us, and late Saturday afternoon our car was headed for Decatur over rough but fairly good roads, and 7:30 p. m. found us looking for hotel accommodations there, made scarce by Sousa's band. This

PICTURESQUE STONE FARMHOUSE IN KENTUCKY.

fifty miles was marked by an exciting race with the electric cars. They would pass us only to be again passed at each station. Incidentally a large touring car joined in the race, but struck a bad place in the road that we luckily avoided, and stopped, and we saw them no more until overtaken in the outskirts of Decatur in stopping to light the tail lamp and display our "number," viz.: initials and address. Leaving Decatur at 7:35 a. m. Sunday, at Oakland a delay of three minutes was caused by the eccentric pushrod that operates the intake valve slipping from place, the only happening of the kind in our experience.

Paris was reached for Sunday dinner. The country thus far was fairly level, and roads fair to good, mostly dirt. Shortly after leaving Paris we started a sleepy old plug of a horse from his nap among the winding hills and he ran in the narrow road in front for two miles, and was so stirred up that he followed as long as we were in sight after passing him.

We Cross the Wabash at Terre Haute.

A hilly country and zigzag roads brought us to Terre Haute, Ind., across the Wabash, at 5 o'clock, where quarters were engaged at the Filbreck hotel. Inquiry as to a State license indicated that little attention is paid to the matter, and, perhaps, unwisely, we took the chance for Indiana and later for Kentucky. Monday morning from Terre Haute automobilists recommended the National road in a northeasterly direction to Indianapolis, a distance of ninety miles. Heavy traffic had damaged this road somewhat, though it was largely good, but very hilly in places. The worst hill was near Reelville, the steep winding kind, and, of course, a team was met right in the middle and a forced stop made, but immediately the car went on up with its load, which, with baggage, top, etc., equaled five passengers. Our car was a model "F," 10-41 gear, not specially geared for mountain climbing, but having all the power needed on the low gear, though at times more power on the high gear would have taken the hills faster. A speed of thirty miles an hour could be attained on the level. This car had already been run 9,000 miles in fourteen months by the writer in his business.

Orchards Were Plentiful.

Orchards innumerable were passed (and some were not), with apples being gathered in huge piles for market. As the summit of a hill was mounted, a teamster, who had fed his team of mules after slipping their bridles, was dozing. Talk about action! We will match him against the world for getting on his feet and bridling the nearest mule and hanging on with a desperate grip, though the mules only gazed in curiosity. No good opportunity presented itself for dinner until at Indianapolis late in the afternoon. As usual, gasoline, oil, and water were procured at a garage and the carbureter adjusted to the new gasoline. The car then headed southward. Boulevards were soon left behind, and the Madison State road taken fifty miles to Columbus, arriving early in the evening over highways that were a motorist's dream of pure joy.

Next morning Columbus was bade adieu early. Rain in the night had not spoiled the roads, which were good to Seymour and poor to Scottsburg, where at noon a rattling good dinner made up for it, as big a surprise as our appearance through such muddy roads. A few minutes was spent here in taking up the driving chain.

Hills Broadened and Valleys Deepened.

From Scottsburg the country began to change, the hills broadening and the valleys deepening. An electric line in process of construction was in sight more or less the entire afternoon, and darkies by the hundreds swarmed the grades and cuts, driving mule teams. More than once a warning hand stopped us while blasting was done with dynamite. Fertile spots of land would no more than get nicely started before rising to timbered hills which seemingly ended at the horizon in a maze of autumnal color beautiful to behold. The striking contrast of numerous

log houses, rail fences and often no fences, with here and there more pretentious homes, brought to our mind the thought that, after all, "there's no place like home" wherever you are.

Near Jeffersonville five cents toll was paid, and soon, with brake held firm and reverse ready for instant use, a steep hill ended abruptly on the bank of the muddy Ohio. Ferryboats alternate between here and Louisville, and 30 cents was the reasonable charge from Indiana to Kentucky soil. Withal it had been a pleasant ninety miles from Columbus, and called for sound, sweet sleep.

It Snowed in October in Kentucky.

Louisville autoists promised extremely hilly roads to Lexington, and, coming to a crossroads blacksmith shop a few miles out, it was decided to halt long enough to have the brake cable made doubly safe. It started to snow—think of it—the 10th of October, in Kentucky. However, the weather soon brightened, and, warmly clad, we were snug as could be with our heavy lap robes. While idly watching work on the brake cable, incidents of the trip were recalled. The ladies were invited into the house, and presently heard a spooky tapping on the door. With suppressed wonder they beheld a large tame goose admitted and fed biscuits from the hand of the housewife. No other food had ever tempted him.

Sign boards showing distance and direction will be great when they sooner or later come into general use. The average person questioned has no idea of distance, but usually makes a guess to oblige, and often you seem to get further away from a town, instead of closer to it.

Know Your Car to Enjoy Touring.

One thing about touring—know your car if you would get the full enjoyment of the trip each day by having that feeling of independence that makes responsibility a pleasure. It does away with garage bills and prevents being hung up on the road. Pay attention to detail and take nothing for granted, and, if you have anticipated by carrying possible necessities, a sane run will mean steady running.

With brake cable strengthened away we go again over Kentucky's famous hard roads, up one hill and down another, gliding safely and surely along through Shelbyville, and later into Frankfort, after a coast of half a mile from almost among the clouds into a picturesque valley, where nestled this pretty city, the capital. At 5 o'clock Lexington, the destination, was reached. Near Versailles had occurred the first puncture, 1905-06 Hartford-Dunlop tires of several thousand miles' prior use serving us well. Lexington and its race meeting of national fame were visited Thursday.

Then Came the Return Journey.

Friday morning, after putting in four new batteries and having the car washed, the return trip progressed over the same route, with unabated interest, to Indianapolis, Seymour being made the first day, a distance of 138 miles, where were met representatives of "THE AUTOMOBILE Official A. A. A. Blue Book." Saturday a glorious ride of 133 miles was enjoyed through Indianapolis and on to Logansport, 70 miles of the distance being straight ahead, without a turn, over the Michigan State road. Here a leak in a water pipe was stopped with tire tape.

Sunday the route taken was from Logansport to Momence, Ill. and as a new road map procured en route indicated no sandy counties, we struck some fifty miles of more or less low and high-gear mixed in irregular doses, not pleasant to take, but with a growing confidence in the single-cylinder Cadillac, if it were possible to increase that confidence. Only twice in these sand hills, when the driving wheels would spin, did the ladies get out, and then only because of a loyal sympathy for the sturdy car, which went through on its own power, no small feat when it is considered that residents there will tell you big touring cars with their added weight often bury themselves and have to be hauled out. Momence was reached at 7:30 o'clock, ninety miles, regardless of conditions.

DESERTED MILL ON THE VERMILION RIVER.

Monday morning found the country immediately changing to good old Illinois soil, and we rolled along through different towns to Morris, thence to Seneca and Marseilles, and back through Dayton to Earlville, where we arrived at 3:30 o'clock, after having been absent 12½ days, visiting 3 days, and covering more than 1,050 miles in the 9½ days' travel. Upwards of 175 towns were visited. One object of the trip was to ascertain from impartial sources what cars in their different classes were giving the best satisfaction in actual use.

Expenses of the Thousand-Mile Tour.

The expense of the tour is here given: Board and lodging, \$53; sundries, \$12.60; storing car nights, \$6.25; washing car, \$2; fifty-three gallons gasoline, \$9.75; lubricating oil, \$2.40, because of overcharging; batteries, \$1.40; repairs, \$1.60; total, \$89.

RAILROAD MAGNATE TO HELP ROADMAKING.

MINNEAPOLIS, MINN., Mar. 4.—President James J. Hill, of the Great Northern railroad, has announced that his road will haul crushed stone free to any part of Minnesota to aid in the cause of good road building.

The good roads question is prominently before the Minnesota legislature now, owing to the introduction of a bill to authorize the employment of convict labor at stone-crushing and road building. The good roads people who advocate the passage of the bill have strong allies in the implement dealers of the State, who are fighting the passage of a bill authorizing the manufacture of farm implements by convict labor. The implement men have issued published statements, which have been circulated all over the State, urging the passage of the Elwell bill for convict labor on the roads.

DRIVING ABOUT THE ILLINOIS STATE FAIR GROUNDS.

CHARACTERISTICS OF VANADIUM STEELS

By J. KENT SMITH AND W. L. TURNER.*

It has been abundantly recorded that the element Vanadium, when judiciously applied in conjunction with other alloys, has very important effects upon steel in the way of largely increasing its static properties (strength and ductility) and, *what is of still greater importance*, of conferring to it extraordinary dynamic stress-resisting qualities such as have hitherto not been met with in other types of special steels. Up to the present, however, little or nothing has been done in this country with the manufacture of vanadium steels. However, a company in Pittsburg having successfully developed a mine rich in vanadiferous deposits in South America, is now undertaking the manufacture of this steel in quantity and of composition to suit requirements.

But Few Sources of Supply.

Before proceeding, it will be of interest to mention a few facts regarding this metal. Its separate existence was discovered about one hundred years ago. Chemists of the day alleged that this element, christened Erythionium, was being confused with the known element Chromium. It was re-discovered about thirty years after this and was re-christened with the name of Vanadium. Its chemical properties were little understood until Sir Henry Roscoe, after an exhaustive investigation of the element and its salts, finally isolated metallic vanadium for the first time.

Owing to the few known sources of supply, it was not considered that vanadium would ever attain more than academic importance, but recent discoveries altered this. The metal has an exceedingly high fusing point (2000° C.) and this alone would be sufficient to prohibit its use in steel manufacture; but from the fact that an alloy of iron containing 30 to 40 per cent. vanadium has a much lower fusing point than that of ordinary mild steel this objection to its commercial employment is removed, while high-class open-hearth steels can be produced by its aid at a reasonable price. Until recently the chief sources of vanadiferous ores of any importance have been:

- 1st—The vanadiferous lead ores of Spain.
- 2d—The ash of the Yauli anthracite deposits.
- 3d—The vanadiferous sandstones of Colorado.

Effect of Vanadium on Steel.

It has been proved that the most successful application of vanadium lies in the direction of quaternary steels, such as chrome, or nickel-vanadium steels. In order to obtain the best results with these elements, it is necessary to add the vanadium in homeopathic doses, with proper precautions, as it is a very powerful medicine and possesses to a very marked extent the property of "elusiveness." One of its most important effects on steel is its power of retarding the segregation of the carbides; examination under the microscope will most clearly exemplify this action and leads to the inference that vanadium steels should be particularly suitable for tempering, as is found by actual experiment to be the case. Being chemically similar to aluminum, vanadium also produces somewhat similar results in conferring soundness on the steels containing it. Further, vanadium appears to toughen the micro-constituent ferrite, and the latter in vanadium steels is shown to have a very closely interlocked granular formation.

Again, vanadium has been proved to be a powerful intensifier of the static action of other alloys. Now, it may be regarded as axiomatic that the employment of an alloy in such quantities as to largely increase the static strength of steel implies dynamic deterioration. Taking advantage of the intensifying action above alluded to, it is possible to obtain largely increased static effect with such a small proportion of the secondary alloy as not to bring about this dynamic deterioration. As vanadium itself possesses perhaps its most valuable property in its extraordinary powers of conferring to steel *added* dynamic excellence, com-

binations are possible which are absolutely unapproachable by any other means available at the present day.

Tests Not Sufficiently Comprehensive.

It has always been the custom to judge the quality or utility of a steel for all purposes by its behavior when subjected to a steady load. It has been the aim of the steel makers to show a high tensile figure, and a certain amount of static ductility at the same time. It has been argued that the standard of quality of steel for all purposes should be gauged by a combination of these two factors. Using the ordinary composition, it was, of course, found that, having exceeded a certain strength, the steel commences to become brittle in the sense that static ductility is being sacrificed. It was then discovered that by using certain other elements in addition considerable increase could be obtained in the tensile figures before any appearance of such brittleness was apparent. The fact that steel could bend cold through a certain angle was looked upon as an additional guarantee of its universal fitness. But no proof has been given of the assumption that a steel which is of the best quality for service under statically applied loads should also come out "on top" when employed in machinery where resistance to vibration and shock is of fundamental importance. It is difficult to see the reason for the continued adherence by manufacturers to the plain tensile test only, as a large proportion of the stresses applied are in the nature of shock and vibration; indeed, it has been calculated that in a high-speed engine between 80 and 90 per cent. of the total stresses are applied dynamically. The eventual result is that ordinary steel will become brittle when subjected to these repeated alterations of stress and will break down, notwithstanding the allowance of a large factor of safety. It has been proved that vanadium retards this deterioration under fatigue and alternating stresses, so that the "life" of the metal is greatly increased. Heat treatment, again, is of direct importance in the preparation of any steel.

Special Grades Being Marketed.

Vanadium steels have undoubtedly brought forth revolutionary possibilities in materials for employment in all machinery and moving parts. The enormous number of laboratory and actual working tests which have been made show their undoubted immense superiority over all other special types for resistance to stress, and this is of great importance in automobile work.

Below are a few of the types designed by the American Vanadium Company to most successfully withstand the specific conditions to which they are to be subjected:

- (1) A type specially prepared for use in machinery in which shock, vibration, and alternating stresses occur, as in crankshafts, axles, piston rods, etc. This steel will withstand a severe shock, as well as a mild steel of only one-third its strength, will resist fatigue to a much greater extent than the highest qualities of ordinary mild steel, and has a wearing surface superior to any known non-brittle material, while its torsional elastic limit is very high.
- (2) A type specially compounded to meet conditions requiring resistance to alternating stresses and shock in the highest possible degree. This steel has the static strength of good nickel forging steel, while dynamically it is enormously superior to the best mild Swedish steel. In connecting rods, piston rods, coupling rods, light axles and similar work, practical difficulties have been overcome by its aid which have been regarded as insurmountable.
- (3) A type designed to resist torsional destruction to a maximum degree, and at the same time to have a comparatively high elastic limit and resistance to shock. Wonderful results have been obtained in practice with this type in holding down bolts and hydraulic machinery.
- (4) A type suitable for the construction of springs of all kinds, both for heavy and light loads. This steel in the raw state may be bent and knotted cold, but when heated and quenched will become hard enough to cut glass. Its coefficient of safe working load when tempered is double that of the ordinary carbon spring steel. Its vitality being extraordinarily high, springs in "difficult" places, subject to frequent overload especially, should be made from this steel.
- (5) A type eminently adapted for all case-hardening operations. A case may be obtained so hard that it can only be indented by grinding, while at the same time a very tough core is obtained having similar tensile figures to type No. 1 above.
- (6) A type of pure low carbon Vanadium steel which is, in its special properties for withstanding vibration, superior to the best wrought iron obtainable, while it welds with the freedom of that wrought iron.

*Chief Metallurgist and Associate Engineer of the American Vanadium Company, Pittsburg.

CLUB NEWS WAFTED IN BY MARCH WINDS

New Jersey Autoists' Endurance Run May 30-June 1.

NEWARK, N. J., March 4.—May 30, May 31 and June 1 are the days definitely fixed for the spring endurance contest of the New Jersey Automobile and Motor Club. It is thought by fixing upon this date to obtain the entry of a large number of club members who could not ordinarily spare three days from their business. May 30 being Memorial Day is, of course, a legal holiday, while Saturday, June 1, will be a half-holiday. Definite arrangements as to the route have not yet been made, but it is expected that the distance will be 350 to 400 miles and that a start will be made from Newark. From this point the run will probably be to Dover via Montclair, Pompton, Butler, Denville and Rockaway. At Butler there will be a control, and at Dover the contestants will stop to lunch. From Dover the run will continue over Mine Hill, through Kenville, Mt. Carmel, and Mt. Freedom to Morristown, where another control will probably be placed. From Morristown the route will lead back to Newark by the regular way through Madison and Chatham. On Friday morning the competing cars will journey from Newark through Rahway to New Brunswick, where the first control will probably be placed; thence to Trenton by way of Hightstown. At Trenton will be another control. It is uncertain what route will be taken from Trenton to Atlantic City, but Camden will probably be avoided and the better route taken passing outside the city. Starting from Atlantic City on Saturday morning, the machines will pass through Pleasantville, Absecon, Port Republic, Tuckertown, Barnegat, Forked River and Toms River, to Lakewood. From this point back to Newark the route is somewhat uncertain and a sub-committee has been appointed to work out details.

At the outset it had been intended to make the competition merely a test of staying power of the competing machines. When the ground was gone over, however, it was found impossible to run the tour on this basis.

Keeping it within the State of New Jersey took the machines over such good roads that a dozen cars might traverse the whole distance without incurring a single penalty. It thus became necessary to introduce some other restrictions, and the only one that seemed practicable was economy of fuel consumption. It is not yet definitely settled that the economy feature will be adopted, but the chairman and other members are of the opinion that it will bring about the best results. One point which will be insisted upon is that the machines shall absolutely adhere to the twenty miles and hour State law. Any car exceeding this limit will be penalized. Under practically all circumstances the machines must be kept running, by which regulation is meant not merely that the motor must be kept going, but that the car itself must not be stopped. The only stoppage allowed for is when a restive horse is met, the driver of which signifies that the car must stop as allowed by law. It is intended to make the competition of such a searching nature that it will be almost impossible for more than one or two machines to come through with a clean score.

Two classes will be provided for, one for touring cars, the other for runabouts. The touring car trophy will consist of a cup donated by W. C. and B. M. Shanley, Jr., while the New Jersey Club will offer a cup for the runabouts. Each automobile must carry the full number of passengers advertised by the manufacturer as capable of being seated in the car. Secretary H. A. Bernell is chairman of the committee in charge of the arrangements.

Rockford Club Elects Officers for Coming Year.

ROCKFORD, ILL., March 1.—After a spirited contest at the annual meeting, the following officers were elected for the ensuing year: La Verne Cole, president; James Rogers, vice-president; Horace Havens, secretary; Dwight Cutler, treasurer. S. C. Andrus was chosen director to succeed Dwight Cutler.

Minnesota State Body Organized for the A. A. A.

MINNEAPOLIS, MINN., March 4.—The organization of the Minnesota State Automobile Association has just been perfected, the first object of the association being to protect automobilists against drastic anti-automobile legislation now pending in the Minnesota Legislature. Four clubs joined the association on its formation, the Minneapolis Automobile Club, St. Paul Automobile Club, Duluth Automobile Club, and Mankato Automobile Club.

The officers of the association are: President, Frank M. Joyce, Minneapolis; vice-president, George M. Palmer, Mankato; secretary-treasurer, H. S. Johnson, St. Paul; directors, H. H. Myers, Duluth; G. A. Lewis, Mankato; Dr. C. E. Dutton and G. A. Will, Minneapolis; Oliver Crosby and T. W. Ingersoll, St. Paul. A committee on legislation was appointed, consisting of Dr. C. H. Kohler and Col. Joyce, Minneapolis; H. H. Myers, Duluth; George C. Knocke and L. A. Wood, St. Paul.

The officers of the club and members of the board of directors and legislative committee include the most prominent men in the automobile and good roads associations of the State. A hearing has been arranged by the House committee, before which the automobile bills now lie, and members of the State association will appear before the committee within a few days. It is planned to push good roads work vigorously through the medium of the State association. Preliminary work has been done on a highway from Minneapolis and St. Paul to Duluth, and the association will push this 150-mile road with vigor. The members of the clubs comprising the State association are practically agreed upon remedial legislation necessary for the welfare of the State and the automobilists, and will have recommendations and amendments ready for submission to the legislative committees.

Discussion was also started looking toward a day of racing at the State Fair this year. A committee appointed to investigate this matter includes S. N. Colburn and Asa Paine, who presided over the Ormond-Daytona races this year; L. A. Wood and Theodore Griggs, St. Paul, and R. E. Brown, Mankato.

Quaker City Club Appoints Its Committees.

PHILADELPHIA, March 4.—Spurred on by the spring-like weather of the latter part of the week, President Swain of the Quaker City Motor Club on Saturday last announced the committees which will serve during the next year. The delay in the announcement was due to the president's desire to appoint no one who could not actively work on the committee to which he was assigned. As a result, quite a number of changes had to be made before the list could be finally completed. Following is a list of the committee chairmen: Membership, A. T. Stewart; house, Nathaniel Hathaway; contest, E. C. Johnson; press, E. H. Fitch; auditing, L. D. Berger; law and ordinances, G. Douglas Bartlett; good roads, A. E. Maltby.

At the regular monthly meeting next Thursday, Chairman Johnson of the contest committee will announce the program for the season.

Successful Banquet of the Staten Islanders.

ST. GEORGE, S. I., March 2.—The Richmond County Automobile Club held its annual banquet to-night at Hugot's Hotel, sixty members sitting down to the elaborate spread. President Charles A. Schultz made a witty and versatile toastmaster. The speakers included A. R. Pardington, vice-president and general manager of the Long Island Motor Parkway, and when he had concluded his optimistic remarks about the special road for automobiles, the Staten Islanders were in a mood to engage him to begin work on a similar highway as soon as his Long Island task is completed.

Other speakers included H. E. Buel, superintendent of high-

ways of the Borough of Richmond; Henry P. Morrison, county engineer before the consolidation, and T. F. Moore, of the New York Motor Club.

The most pleasing feature of the evening was the presentation of a handsome loving cup to J. J. Worrell, the hard-working secretary of the organization. William S. Van Clief, president of the Richmond County Agricultural Society, made the presentation speech, to which the recipient of the cup responded in a happy and appreciative vein.

Plans of the New York Motor Club.

NEW YORK, March 4.—At the recent meeting of the directors of the New York Motor Club, with President S. B. Stevens presiding, it was decided to hold a club smoker on the evening of March 15. Preceding the vaudeville part of the program, there will be a six vs. four-cylinder discussion, in which have been invited to participate representatives of leading makers. It is expected that a formidable array of speakers will be secured for both sides of the discussion, which will be followed by high-grade vaudeville features and refreshments. It is among the possibilities that the club will soon be located in larger and more commodious quarters, there being some talk of renting an entire house near the Broadway automobile district.

In the form of an advisory committee to the board of directors the following were designated: A. R. Pardington, S. A. Miles, Alfred Reeves, C. B. Rice, John Kane Mills, George McKesson Brown and T. F. Moore. These will be added to the board as soon as the necessary constitutional changes can be effected. A. B. Tucker has tendered his resignation as secretary.

Tacoma Automobilists Active for Good Roads.

TACOMA, WASH., Feb. 28.—At the annual meeting of the Tacoma Automobile Club a special committee was appointed to raise \$5,000 to aid in the paving of Center street, which illustrates that the club members are willing to pay for what they think will be of public benefit. The main idea of the club is to get concerted action on such schemes as are necessary for the proper pleasure of autoists. The ultimate aim is to have a club which will be somewhat social in character and which will have regularly appointed runs; but at present the organization is working for better roads in the city and adjoining country and for permission to enter the Government reservation at Paradise Valley.

Under existing conditions automobiles are not allowed within the national park there. The reason for this is not known. The Tacoma Automobile Club, through Congressman F. W. Cushman, is attempting to have this regulation repealed, and if successful will devote a part of its efforts to building a road from Tacoma to connect with the Government road being built on the reservation. If, however, the Government refuses to give the required permission, the club will gain no good from helping to have the road built, and, in all probability, the scheme will be dropped.

The following officers were elected for the current year: President, Chester Thorne; vice-president, Richard Vaeth; secretary, H. H. Gove; treasurer, Fordyce Taber; trustees, John F. Lyon, J. C. Donnelly, and Calvin Phillips.

Long Island A. C. May Rejoin the A. A. A.

BROOKLYN, N. Y., March 5.—Growing sentiment in favor of a renewal of the membership of the Long Island Automobile Club in the American Automobile Association is taking a pronounced form, and an early return to affiliation with the national organization is predicted by the knowing ones. In withdrawing from the A. A. A. the Long Island Automobile Club was criticized. The action of the local club was construed by some to mean that it wished to take no more active part in furthering the cause of the autoist. This is far from the case. It would be hard to find a member who is not intensely interested in every move made to help along the man who wants to use the automobile. The local organization felt that it was not receiving an adequate return for the money which was paid as dues to the

national body. Since last year the American Automobile Association has undergone a change which, in brief, leaves to the different State associations affiliated with it the bulk of the work of guiding legislation, promoting the cause of good roads and other moves calculated to be of benefit. Seventy-five per cent. of the dues now paid go into the treasury of the State bodies, the other 25 per cent. only passing into the national treasury.

The Long Island Automobile Club has always been a believer in the great good to be derived by pooling interests in the united action made possible by a State body. Many of the members believe, however, the time is now ripe to again join hands with the men who are pledged to protect and further the interests of the automobilist in every way possible.

Harrisburg's Motor Club is Organized.

HARRISBURG, PA., March 4.—Local automobilists and motor boat enthusiasts have organized the Motor Club of Harrisburg and have elected former Mayor Vance C. McCormick, president. The other officers are: First vice-president, Oscar C. Robertson; second vice-president, R. R. Buvinger; third vice-president, Charles C. Cumbler; secretary, J. Sidney Sible; treasurer, John C. Nissley. The board of governors consists of Dr. John Oenslager, Herbert F. Rawll, C. G. Nissley, James A. Bell, James McCormick, Jr., Roy Senseman, A. Stees, Frederick D. Carney and Howard Jenkins. The following chairmen have been appointed to head the special committees: Membership, R. A. Sef-ton; house, I. W. Dill; exhibitions and runs, R. C. Haldeman; laws and ordinances, D. C. Haldeman; auditing, H. C. Wright; roads, J. C. Nissley.

One of the first steps to be taken by the new organization will be to secure better roads in the vicinity of this city. The roads leading into the Capital City are in terrible condition at the present time owing to the refusal of the supervisors to apply for State funds. The exhibition and run committee is arranging for a two-day endurance run during the latter part of April which will include Lebanon, Lancaster, Columbia, York, Hanover, Gettysburg, Chambersburg and Carlisle in the itinerary. An automobile parade and other contests are planned for the summer. The club has a charter membership of 130 of the most prominent business and professional men in the city.

THE AUTOMOBILE CALENDAR.

AMERICAN.

Shows.

- March 9-16.....—Boston Automobile and Power Boat Show, Mechanics' Hall and Horticultural Hall, Boston, Automobile Dealers' Association. C. I. Campbell, mgr.
- March 13-16....—Omaha, Auditorium, Second Annual Automobile Show, Omaha Dealers' Association. T. Gillman, manager.
- March 18-23....—Providence (R. I.) Automobile and Power Boat Show, Infantry Hall. F. M. Prescott, manager.
- March 21-30....—New Haven, Conn., Second Regiment Armory, Automobile Show, under the auspices of the local dealers.
- April 1-6.....—St. Louis, Mo., Automobile Show, Jai Alai Building, St. Louis Automobile Dealers' Association.
- April 6-13.....—Montreal, Canada, Second International Automobile and Sportsman's Exhibition. R. M. Jaffray, manager, 309 W. Notre Dame street.
- April 8-13.....—Pittsburg, Pa., First Annual Show of the Pittsburg Automobile Dealers' Association, Duquesne Garden.

Races, Hill-Climbs, etc.

- April 1.....—St. Louis, Mo., Auto Floral Parade, Automobile Club of St. Louis.

- May 30.....—Philadelphia, Hill Climb, Quaker City Motor Club.
- May 30 June 1...—Newark, N. J., Endurance Run, New Jersey Automobile and Motor Club.
- Oct. 19.....—St. Louis, Mo., International Aerial Race for the Gordon Bennett Prize. Aero Club of America.

WIDESPREAD INTEREST IN A. A. A. ANNUAL TOUR

THE exact route and the rules for the Glidden and other trophy contests involved in the annual tour of the American Automobile Association may not be announced for a week or more, despite the fact that the Touring Board held a meeting at Buffalo, March 1, and formally organized by selecting sub-committees, the chairmen of which compose the Executive Committee, the head of which, of course, is Frank B. Hower, the chairman of the entire board. James B. Dill, East Orange, N. J., is chairman of the Touring Information Committee; L. E. Myers, Chicago, of the Foreign Touring Committee, and Philip S. Flinn, Pittsburg, of the Road Signs Committee. Dai H. Lewis, Buffalo, is to serve as the special secretary of the Touring Board.

Judge Dill's sub-committee has twenty-six members, and its duty will be to assist in the accumulation of all kinds of touring information, which shall be kept by the secretary of the A. A. A. for the benefit of all members. In like manner the committee of twenty-seven, headed by Mr. Myers, will obtain foreign material. Mr. Flinn's road signs work will include the formulating of plans to bring about the marking of the trunk roads of the country, either through the aid of local laws and authorities or by co-operation of State associations and clubs.

The Buffalo meeting agreed upon several necessary changes in the deed of gift for the Glidden trophy, and Mr. Glidden will be asked to assent. The most important change is one suggested by the Automobile Club of Buffalo. Percy Pierce, winner of the trophy in 1905, and retaining same for the Buffalo Club through tieing with the other clean-score participants in the 1906 tour, was a factor in advancing the change which would prevent the Buffalo organization keeping the trophy in case of another tie. In this event the trophy might go to the club which supplied the most survivors, but it is understood that the desire of the Touring Board as a whole is that the 1907 contest shall be of such a strenuous character that the possibility of ties will be greatly reduced.

The Executive Committee of the board had a conference on Wednesday of this week with the Contest Committee of the National Association of Automobile Manufacturers, which some time ago had in mind the running of a series of contests for

stock cars, but recently came to a decision that amounts to the giving up of the idea. As a result of the conference between the A. A. A. officials and the N. A. A. M. representatives, something definite may be expected in the near future. It may be that there will be a conference involving the N. A. A. M., A. L. A. M. and A. M. C. M. A. and the Executive Committee before all the details are decided upon.

As to the route, there are those who advocate a start in the West and a finish in the East; those who hold to the contrary and want the start in the East and the finish in the West; with a third element asking for a start in the East and a turning point in the West and the finish in some Eastern city other than the starting point. Unquestionably there is keen interest in the affair, and the entry list promises to be substantial, no matter what route is chosen.

The Hotchkiss Administration is Making Great Headway.

On the heels of the report of the formation of a Minnesota State Association of the A. A. A., containing four clubs and over 800 members, comes two conferences this week that may bring about two more State bodies. Last night at Philadelphia there was a conference of President W. H. Hotchkiss and other members of the Executive Committee with President Isaac Starr, First Vice-President Robert P. Hooper, and Secretary Paul C. Wolff, of the Pennsylvania Motor Federation, which possesses fifteen clubs and has upwards of 1,500 members. To-night, at Bridgeport, Conn., there will be a conference with representatives of several Connecticut clubs. A Connecticut body is practically assured, and it will probably start out with the Hartford, New Britain and Bridgeport clubs as the nucleus.

Secretary F. H. Elliott will take a trip through the Middle West next week to attend meetings in Michigan, Indiana and Kentucky, in all of which States organization work is already under way. Tentative organizations have been formed recently in Wisconsin and Missouri, and from present indications there will be six or eight applicants for State membership at the March meeting of the A. A. A. Board of Directors, which will take place the latter part of the month.

FEDERAL BILL OF THE A. A. A. IS NOW UP FOR DISCUSSION

A START has been made by the American Automobile Association in the direction of national legislation concerning automobiles. Chairman Chas. T. Terry of the legislative board last week went to Washington and had introduced through Representative Cocks of New York a bill entitled "An Act Providing for the Regulation, Identification and Registration of Motor Vehicles Engaged in Interstate Travel." It was not expected that action could be obtained at the session of Congress which has just closed, but it is anticipated at the forthcoming Congress of next December that the measure, which was referred to the Committee on Judiciary, will receive early attention, and automobilists who have examined its provisions are confident that it will be declared constitutional if it becomes a law. The main features of the measure are as follows:

(1) **Exemption from registration provisions of State laws other than the laws of the State of the owner's residence.** Thus: On compliance with the provisions of the act with reference to previous registration in the State of the residence of the applicant, and on filing with the bureau created by the act of a verified application, which application shall state among other things the name and residence of the applicant, his State registration number, a description of the vehicle, the manufacturer's number, the character of the motor power and the amount of such power stated in figures of horsepower, such bureau shall issue to the applicant a certificate of registration and a federal number. Thereafter in travelling anywhere in the United States outside of the State of the owner's residence, such owner shall, by displaying the federal number on the front and rear of his motor vehicle, be exempt from

the laws of other States regulating registration and the carrying of numbers.

(2) **The Identification number or sign.**—The provisions of the act require that while the vehicle is in a foreign State, such number shall always be displayed both in front and in rear; the number to be three inches high, with the initial letter or abbreviated designation of the State where the vehicle was originally registered at the left of such number and the initials of the United States at the right of such number.

(3) **The Motor Vehicle Bureau:** The act will create in the Department of Commerce and Labor a bureau in charge of a commissioner with a secretary and clerical assistant. To such bureau will be sent all applications, and in it will be kept records of the vehicles registered, indexed for ready reference and the supplying of information on all proper requisitions for the same. Salaries are provided for the commissioner, secretary and clerical force, payable out of the fund created by the registration fees. Such fee will be \$5 in the case of an individual and \$10 in the case of a manufacturer.

"The Congressmen who studied the provisions of the bill," said Mr. Terry after returning from Washington, "seemed highly pleased with it. They all expressed their satisfaction that the bill was presented at this time because it will offer ample opportunity before the next Congress for its provisions to be thoroughly discussed, and any amendments or additions that might be necessary will be in readiness for discussion as soon as the bill comes properly before the House. I may be enthusiastic, but I sincerely hope and expect to see the bill a law within a year at least, probably less. It will become a law 30 days after being signed."

The Road Question Is Up to the Automobilist.

"If I read aright the signs of the times, the hour has come for the automobile interests to take up the road question as their question." Thus writes James W. Abbott, a prominent ex-commissioner of the Office of Public Road Inquiries, and a man who has argued and talked for good roads these many years. Mr. Abbott's very able comments will be read with keen interest, and his opinion should carry the weight of an authority whose observation has been unbiased except to the extent of working for that which he believes to be for the general good of the entire country in the establishment of a road system which will compare with the ideal kind of the far-seeing French.

Mr. Abbott believes that the automobile has captured the farmer, and he predicts that the country nabob will soon plow, plant, sow, and till his fields and gather his harvests with motor devices. Mr. Abbott suggests, as he did several years ago, that the automobile, carriage, farm vehicle, street paving, brick making, and other industries should be represented in a national organization, the existence of which should be for the building of good roads. It might be noted that of all these interests he now places the automobile first, and the reason for so doing is becoming plainly more apparent every day.

In the future building of these roads there may come the necessity of a radical change in the present method of construction, for it cannot be denied that the coming of the automobile is exacting from our roadways a mileage many times greater than has been called for by the horse-drawn vehicle.

Advance in Metallurgy Due to the Automobile.

Apart from the fact that the automobile as typified by the gasoline type of car, with its internal combustion motor and sliding gear speed changes as an essential link in the transmission of the power, is proving an unqualified success despite the voluminous predictions of some years ago to the contrary, nothing has served to emphasize the position it now occupies so much as the advances in the art of metallurgy for which it has been responsible. Considered as a piece of machinery, the automobile costs more per pound than any similar piece of mechanism manufactured, and this, it is averred, is the reason why its makers have been able and willing to pay prices far beyond the reach of makers of other classes of machinery.

Strength, combined with lightness to a degree never before found necessary, had to be attained at any cost, and the result has been an impetus to the art of alloying steels, such as it could not have received from a quarter of a century of development in the ordinary course of events. The 12 and 15-horsepower cars of several years ago were already beyond the economic weight limit, both where tires and other considerations were concerned, so that a reduction of the weight was as imperative as an increase in power; but one could not be brought about without the other. The limit of development seemed to have been already reached in the case of carbon steels, so that the matter of alloying, supplemented by scientific heat treatment, was taken up and has been carried to an unprecedented degree.

To appreciate what has been accomplished, it is necessary to consider the modern automobile: carbon steels have given way to nickel-steel, and the latter, in turn, to chrome-nickel-steel, both having been brought to an unprecedented degree of improvement through the great amount of study devoted to the subject. And now we are to have vanadium steels—which from the rarity of the alloying component have hitherto been considered unduly expensive even for the automobile, though used to a limited extent on automobiles constructed abroad.

Further Progress in Alcohol Legislation.

Though loth to accede to the popular demand for legislation along this line, as was demonstrated by the number of years required to pass the Free Alcohol bill of last year, Congress having taken the first step, is evidently not going to be allowed to stop half way, as is shown by the action of the Senate during the past week. What this means to the automobilist will doubtless take several years of development to demonstrate, but that it will result in the ultimate good, not alone of one class of liquid fuel users, but of many, cannot be gainsaid. It has been claimed all along, that the bulk of the gasoline used to-day is consumed by the farmer in small stationary engines and in cooking stoves, and this being a fact, the granting of the right of the agriculturist to make his own fuel should certainly tend to relieve the situation to a great extent, though relief may be slow in coming.

The U. S. A. as a Market for British Cars.

Every Englishman connected with the industry who has come to this country, whether for a stay of a week or three months, has been visibly impressed with the great number of automobiles in use and the wretchedness of the roads their owners have to put up with, and has hardly been able to contain himself until he could get back home to tell his confrères about it. He pictures to himself a vast field for the British automobile to conquer and sets about to enthuse British makers in the propaganda of exports to America, citing the success of Continental makers to witness the golden harvest that awaits the reaper. The Hon. C. S. Rolls proved no exception to the rule. It would appear superfluous to call attention to the fact that more American automobiles are sent to Great Britain every month than there are British cars in this country all told, and the number of the latter does not grow in a manner at all indicative of a promising future.

WHAT FRELINGHUYSEN NOW SUGGESTS.

TRENTON, N. J., March 4.—Senator Frelinghuysen has somewhat modified his ideas, according to the bill which he has introduced in the New Jersey Legislature. It provides for the registration of cars and licensing of drivers, fixes rules regulating the use and speed of such vehicles, fixes license and registration fees and provides penalties, authorizes the Secretary of State to appoint twenty-five inspectors at \$3 a day each, and as many private citizens to act as special inspectors, gives State Commissioner of Motor Vehicles \$1,500 a year, in addition to his salary as Assistant Secretary of State, gives the chief inspector the same salary, provides for three days' license for tourists at \$1 each, and calls for persons residing outside the State to file address of counsel upon whom service may be made in case of accidents in this State.

It will be noted that there is no reciprocal registration clause, but \$1 a day is asked for what is designated as a tourist's license. It was stated that Senator Frelinghuysen had given assurances to several prominent New York automobilists that his new bill would include reciprocal registration.

AMENDED DENATURED ALCOHOL BILL PASSED.

WASHINGTON, D. C., March 2.—After a lengthy debate the Senate passed the House bill amending the denatured alcohol act, and it is now in the hands of President Roosevelt, awaiting his signature becoming a law. The object of the bill is to relax the Government inspection to permit the manufacture of alcohol for denaturing uses in small quantities along the lines of the German law. The new act is intended to satisfy the complaints of Western farmers, who claim that the original free alcohol law passed last year was so framed as to deny them the benefits which the legislation as originally planned was designed to confer.

An amendment submitted by the Finance Committee came near wrecking the bill. The object of this amendment was to require a Government storekeeper to be present during the entire period of distillation of spirits. It was pointed out that this would involve so much expense as to make the operation of the law impracticable in its relation to small distillers in agricultural communities. The amendment was lost, and then the bill was passed.

GOLD CUP TOURISTS WILL SAIL JUNE 20.

American autoists engaged in the 4,000 miles' tour through Europe for the American Gold Cup will leave New York June 20 on the *Provence*. The machines will be sent in advance on the French liner *St. Laurent*, sailing from New York June 7. Immediately on arriving at Havre the caravan will proceed to the Dieppe district to witness the Grand Prix race of the Automobile Club of France, after which they will begin their six weeks' run through the different countries of Europe. The entries already received for the tour include the Welsh, Thomas, Pierce, Cadillac, Packard, Stearns, Moore, B. L. M., and Columbia. Individual entries have been booked from Vancouver, Alberta, B. C., and Fort de France, Martinique. The entry list will close on May 15.

FOURNIER'S OFFER TO THE GOLD CUP TOUR.

Henry Fournier, well known in this country because of frequent visits here in years past, and now the manager of Paris-Automobile, 48 Rue d'Anjou, comes forward with the generous offer of providing free storage for the American cars which participate in the European tour being promoted under the direction of Georges Dupuy, now of New York City, but formerly of Paris. Mr. Fournier is the manager of one of the largest garages in Paris, possessing a capacity of 400 cars, and its location is decidedly convenient, being in the very central part of Paris. A special part of the garage, or a floor quite closed, will be provided for the American cars during their visit to Paris.

FORD HAS THE MOTOR TRACTOR IN MIND.

DETROIT, March 3.—Henry Ford has returned from a six weeks' vacation in California and Southern points. The rest was the first Mr. Ford has taken in six years. While in the West Mr. Ford looked thoroughly into the possibilities of motor traction, a phase of the motor industry that he has made a pet of the past few years, though he has said little on the matter.

"There are vast possibilities for motor traction in the West," said Mr. Ford, "were it possible to secure fuel at a reasonable rate. At the current price of gasoline, however, the outlook is none too bright, and there is no telling how far the price of gasoline will advance. Steam is used considerably, and giant ploughs that turn forty furrows at once are used in some cases on the plains. With fuel practicable at half the present cost, the motor traction phase of the industry would be practically unlimited.

For the present Mr. Ford will devote most of his attention to the construction of the six-cylinder racing machine that the company will send after the Vanderbilt cup this year. The plans are all ready and work will be commenced immediately. It is expected that the racer will be ready for the road in April. It is understood that the car will be turned over to Kulick, the well known driver, who will tune it up and probably drive it in the elimination. As the Wayne people also have just announced that they intend to enter a car in the Vanderbilt race this season, interest in this great classic will run high in Detroit. The Ford racer will be constructed of Vanadium chrome steel.

TWIN CITIES WANT A. A. A. TOUR START.

MINNEAPOLIS, MINN., March 4.—Minnesota is the latest claimant for the A. A. A. tour of 1907. The Minnesota State Automobile Association, recently formed, will urge the starting of the tour from Minneapolis and St. Paul, or from Duluth, if the Tri-City highway to the Head of Lakes can be completed in time. The Chicago-Twin City endurance run of 1905 furnished a substantial test of cars, although bad weather made the run unsuccessful in some of its features.

MISSOURI'S PROBABLE NEW AUTO LAW.

JEFFERSON CITY, Mo., March 4.—The Botsford automobile bill, requiring a State license costing \$5 and permitting the operation of an automobile anywhere in the State, was passed by the House to-day by a vote of 98 to 5. It is expected that the Senate will take similar action. The present law permits each county to require a license, and there has been no end of inconvenience.

WEBER BILL RECOMMITTED FOR A HEARING.

ALBANY, N. Y., March 5.—The Weber bill, which would require non-resident automobilists to take out New York State registration, was to-day recommitted to the General Laws Committee of the Assembly for a hearing. The impression prevails that the bill will never become a law, unless it is urged by the New York State Automobile Association, which at present is antagonistic to the measure.

N.A.A.M. DOES NOT DESIRE ASSOCIATE MEMBERS.

Associate members of the National Association of Automobile Manufacturers have received a communication from the Executive Committee, stating that it is the desire to abolish the associate membership and make the organization one of active members exclusively. It is stated that the manufacturers of automobiles feel that the association can render no service whatever to associate members. Therefore resignations are being solicited.

CHAIRMAN HOOPER, TO REPRESENT PENN.

Robert P. Hooper, Chairman of the A. A. A. Good Roads Board, has been appointed by Governor Stuart, of Pennsylvania, to represent that State in the annual convention of the American Road Makers' Association, at Pittsburg, March 12-14.

GEARLESS TO MAKE ITS DEBUT AT THE HUB

OWING to the fact that the show at the Hub usually marks the wind-up of the show season in this country, it is generally productive of a number of new things that could not be gotten ready in time to exhibit at the earlier shows. Two of these that will be uncovered for the first time during the event

THE RADIATOR.

that will hold the boards for the week beginning next Saturday are the Gearless touring cars. Taken as a whole, both these cars are something in the nature of a novelty, as they have never been publicly shown before, and, in fact, have only been completed in time to be included in the Boston show, but their chief distinguishing feature—the gearless transmission—is something that has been before the trade for some time past and has demonstrated its utility in a satisfactory manner. In addition to this feature, they embody a number of novel points, which it is confidently expected will cause their entrance on the market to be something in the nature of a sensation to the trade. They are the result of two years' steady work and experimenting on the part of the Gearless Transmission Company, Rochester, N. Y., and will have the distinction of being the highest powered cars on the American market for the price. Their builders will have the further distinction of being the only manufacturers in the country devoting their attention to both the two and four-cycle types of engines, one of each of the cars to be staged being of these differing types.

Model 60 is the two-cycle type and is a 60-horsepower car, equipped with a four-cylinder, two-cycle engine, the cylinders of which have a five-inch bore and five-inch stroke. Particular attention has been paid to the matter of ignition, and after much study both the plugs of the duplicate systems with which the car

is provided, have been placed at the side of the cylinder, quite close to the top, rather than directly in the head itself, as has been customary with the majority of designers. This location has been found to be one that insures the proximity of fresh mixture to the plugs and consequently facilitates the spread of the explosion, with a corresponding increase in the power developed. One set of plugs is run from a standard high-tension equipment, employing accumulators as the source of current, and the other set, entirely independent of the first, is run from a magneto. The motor has been demonstrated to have a capacity of fully 60-brake horsepower on the test block.

The makers are not ready to give full detailed information of the design of the engine at the present time, but wish it understood that it is a motor of the two-cycle type, free from those defects thought to be inherent in this class of engine. It is said to be extremely flexible and responds to the throttle to the same degree as a four-cycle motor. Another distinguishing feature of this car is the transmission, which, as already mentioned, is gearless, but which does not, however, employ any friction disks, its

GEARLESS MODEL 60, WITH FOUR-CYLINDER, TWO-CYCLE MOTOR.

simplicity being such that but three moving parts in all are required. A full technical description of this will also be given in connection with that of the engine itself. The car has a 124-inch wheelbase, with 36 by 4-inch wheels, and in every respect embodies only those features of design, construction and materials that have come to be considered as standard by the best known designers.

The other car to be shown is no less a surprise, in that it marks an addition to the six-cylinder ranks. It is known as Model 75, its power plant consisting of a six-cylinder motor, the dimensions of which are 4 13-16 inches by 5 1-2 inches—an unusually large engine for one of the six-cylinder type, so that although its official title is as given above it will be popularly known as the "Gearless Great Six." The motor has a capacity of 75-horsepower at a moderate speed. As its name indicates, this car is also equipped with the gearless transmission described above, and is along the same general lines as the two-cycle car, except that it is somewhat heav-

MODEL 75, GEARLESS, HAS SIX-CYLINDER, FOUR-CYCLE MOTOR.

ier in construction throughout, the wheel base being 128 inches and the wheels 36 by 4 1-2 inches. Both cars are provided with extremely attractive straight-line bodies, comfortably seating seven passengers in the case of the latter, extra revolving chairs

SIXTY-HORSEPOWER, TWO-CYCLE GEARLESS MOTOR.

being used in the tonneau. The 60-horsepower two-cycle car lists at \$3,250 and the "Gearless Great Six" at \$4,000, both in complete running order and with the usual equipment of accessories.

CHICAGO MOTOR DISPATCH'S ARRAY OF LOGANS.

CHICAGO, March 4.—Twenty model N Logan light delivery wagons are being used exclusively by the Chicago Motor Dispatch, these being received recently from the factory of the Logan Construction Company at Chillicothe, O. These cars are all painted in dark wine color, with gold stripes and lettering, consecutively numbered. Their appearance is businesslike.

The object of the Chicago Motor Dispatch is to handle parcels and packages accurately and rapidly in Chicago, the company consisting of five men of experience in the express business. The parcels are first called for by a force of pick-up wagons and taken to the Motor Dispatch's clearing house at 347-349 Wabash avenue, and there sorted for delivery to all parts of the city. Before the end of the year the Motor Dispatch expects to double its number of Logans, for the tributary business interests in Chicago express much satisfaction at the excellent service supplied by the motor route. John D. Maus, for nineteen years associated with Kelly, Maus & Co., is the president and general manager, the other directors being J. Brown, Jr., vice-president; Graham F. Duffield, secretary and treasurer; Ralph A. Bond, and Vincent Walsh, all of whom are experienced in this line.

LOGAN LIGHT DELIVERY WAGONS, BUILT FOR THE CHICAGO MOTOR DISPATCH, READY TO LEAVE FACTORY AT CHILLICOTHE, O.

CASWELL BECOMES HEAD OF INTERSTATE CO.

At its second annual election, held at the company's offices at 1931 Broadway, last week, Louis S. Caswell was elected president of the Interstate Automobile Clearing Company. The other officers are James Geary, vice-president; James M. Carples, secretary, and F. I. Hauptman, treasurer, the directors being William B. Thom, William E. Metzger, William J. Dixon, John Slattery, Herman F. Cuntz, Charles A. Wardle, James Geary, F. I. Hauptman and L. S. Caswell. In its operations this concern holds a unique position in the automobile field. It neither buys nor sells cars though its dealings are entirely in used cars. What it does do is to find buyers for those who wish to dispose of second-hand cars, and cars for those who wish to acquire one that has already seen service, thus doing a purely brokerage business, but covering the entire country. A registration fee is required to cover the cost of advertising and a small commission is charged the seller on the amount for which the car sells. Both buyer and seller are accordingly benefitted.

CONTINENTAL CAR AND DESIGNER JOHNSON.

THE NEW CONTINENTAL AND ITS DESIGNER.

One of the latest entrants into the field is the new Continental, a car of foreign design, which will claim New Haven, Conn., as its home. The photograph shows C. S. Johnston, its designer, at the wheel, about to start out on a 100-mile test over the snow-covered roads. With him in the new roadster is E. W. Bean, consulting engineer, and standing beside the car is S. R. Ryman, master mechanic of the University Automobile Company, of New Haven, which is undertaking the construction of the new car. This concern, of which Mr. Johnston is president, is also agent for the Wayne cars and expects to be able to supplement these with the new productions of his own creations in time to make deliveries for the coming season.

THERE WERE MANY SNOW COVERED MILES WHERE THE CAR WAS LET OUT INTO ITS GREATEST GALLOP.

THE SNOW-BLOWN STORY OF A WINTER TRY-OUT

By A. PASSENGER.

“HIRAM” was what we christened the 1908 Packard experimental car after we had braved the snow and the cold for a 606-mile round trip between Detroit and Chicago. “Hiram,” or, as he was then known, “Number One,” had scampered over the boulevards of Detroit for about a month, and there was considerable curiosity concerning his ability to trip over the nerve-racking highway which connects Detroit with Chicago. A run was arranged. The pilot was Sales Manager Waldon, who has driven experimental Packards over that particular road of jolts and jars so often that he ought to be able to write a syncopated poem about it. Four of us of the proletariat constituted the ballast-pneumatic-tire Red Cross corps.

It was before 6 o'clock and the sun was still abed when we gathered at the Cadillac Hotel. Waldon's fur-framed face, as he burst into the warm lobby, was serious. Seated at the greasy table of an all-night dispenser of coffee, rolls and once-eggs, we talked over the chances of the road ahead of us. There was no recent report on which to build a prophecy of any kind and the only visible sign was a void of wintry desolation and darkness.

Michigan avenue was wrapped in a cold chill. It is fashionable now to listen to the “Call of the Wild,” and make your friends think you are a regular wolf-dog, impatient to dash across the snow and through the ice-mantled forests. However, there is a yellow streak in a soul accustomed to steam heat when it comes to choosing between a fine hotel and a wind-swept snow road about five-fifty of a winter morning.

We Got Back to Nature.

Back to nature? We certainly got back that day and the next and the next. For the first few miles along the macadam leading out of town there was much levity. We discussed the car we were in and guessed at things to come. In the growing light we caught glimpses of ourselves in shop windows which shot rearward. It was not a pretty car and one would little think it the first impression cast in the mold of the future season. The body was passé by a couple of seasons, and fitted its frame much as some of our borrowed furs fitted ours.

A few hardly curious and very sleepy early risers watched us rush out of town. We fidgeted around in the tonneau, adjusting our bulky shapes and the paraphernalia of touring which reposed on the floor. We divided the task of record keeping into looking at the speedometer, at a watch, and at making marks on a 5-cent

note book. Soon we settled into the half slumber that follows too early awakening and let the vigilant Waldon study the long stretch of tiresome perspective leading into farm land.

The cold brought us back to life. The day was full born but gray and drear. We were apparently alone on the face of the earth. Waldon said it was our duty, in the tonneau, to wave at all farmers we met. We looked hard for farmers to wave at. The watchkeeper hunted in his voluminous clothes for the timepiece that he might note our arrival at a town. His right fur mitten was picked up by the wind and carried overboard. Waldon laughed and we flew onward. A mile further down the road I lost a mitten trying to write Ypsilanti in the note book as we jostled along about 55 miles an hour.

A Panorama Painted by Jack Frost.

We were in real farmerland now. Rolling ground gave us a wide panorama painted by Jack Frost in blinding white. The snow was on everything but us. Only in the far distance, where irregular lines of trees rose to partially obscure the horizon, was there anything not white. The sun flirted shyly with the landscape and cast opaline pictures upon the great white screen. It did not warm except in appearance. The cold penetrated with a sharpness that cut through fur and sweater. We began to hunt for the warm corners of the tonneau. There was great simplicity and beauty in the wonderful white vista before us. But even the crisp crunching of dry snow under our flying wheels lost its music and became the chant of a frozen elf who tormented us.

The sun lost itself behind a bank of grey evil clouds. The opals vanished. The snow deepened. The houses seemed farther apart, forlorn, deserted. Everything was bleak. Hills rose and sank as the road climbed icy, wind-blown summits and dropped into uncertain hollows where the snow might be a foot or a mile deep. We wallowed in the drifts and slid over the slippery, rough swept places. The wind beat the drifting snow against our faces. It felt like the sharp prick of a thousand needles and often we would touch our faces as though to wipe the blood away. Waldon told a funny story. I never knew whether this was a bluff or whether he was really immune to the gale of snappy frost.

The Road Was Ours Alone.

It was time that we should meet the pious farmers on their way to the country church. We did not meet them. The road

MORGAN.

FREDERICKS.

WALDON.

LOOMIS.

ESTEP.

was ours. Rural Michigan worshiped by its own cook stove that raw Sabbath day. We could not guess at the time. The sun shone from nowhere. Only occasional glances at the watch as we passed through towns guided our calculations of the day's progress. The speedometer told us that we were reeling off mile after mile at express speed; for all that we slid on the ice and struggled rudderless in the snow.

At Coldwater we took on gasoline for safety's sake, although there was plenty in the tank and we had a ten-gallon can in the tonneau. We stretched our legs and clapped our hands and stumbled and rolled into the hotel to get rid of a little of the sting before we started again.

All that morning and in the afternoon the flight across the drear waste of a snow-buried country continued. We ran through an area where it had melted, but was now freezing again. The cold was augmented by our windy dash through it. A dirty mixture of sand, clay, and melting snow was hurled up at us in a constant stream, striking car and passengers alike and freezing where it struck. Soon we were ice-coated from end to end, enameled in frozen mud. The steering was difficult now. Not only was the pathway fickle, but the steering gear was encrusted with ice and its lubricating grease frozen into solder.

Struck the Deep Drifting Snow.

As we worked our way out of this district of slush we struck again the deep drifting snow. The road was buried. Only the trees and the fence tops outlined the highway. There was one long wavering stretch which I remember, where it seemed as though we were striking across a desert or that we were on top of some once-inhabited region now buried beneath its great burden of snow. We ran into a valley and crossed and recrossed the St. Joe river. The bridges creaked and groaned. The trees along the low edges had been inundated. The water was gone but had left a collar of ice around each tree. The only simile I could think of was the immaculate ruff of Sir Walter Raleigh. That reminded me that I had not smoked since leaving Detroit. By blowing the smoke through my nose I discovered that I could warm the whole front of my face.

Pretty soon the landscape lost its wild, frozen charm and became human with brick pavements, trolley wires and houses with lace curtains. It was Elkhart, but Waldon never hesitated. There was a momentary warm breath and then once more the icy blast of the open country struck us. We nearly passed a corner that should be turned. The steering was now frozen so stiff that both of those in the front seat had hold of the wheel. They yanked and tugged at it. The car came round but came too slowly. Then we stopped—in a snow drift a few feet deep by a fence. We kicked the snow around and shoveled it out with a corset sign that belonged on a fence in a warmer clime.

Once more on the road, we sank again into reveries and our furs. Waldon and his companion of the front seat struggled with the wheel but did not let up on speed.

Bang! We Knew That Sound.

Bang! We came up out of our furs and our reveries. We knew that sound. There may be the stimulus of excitement when changing a tire in the Vanderbilt Cup race. You never

really curse the rubber industry in your heart until you fix a tire on a snow-drifted, windy country road.

We were close to a house and drove the car into its yard, where we started to work on the lee side of a hen-coop. This small protection was but a frost-bitten farce, so we drove into a brick yard further back. Here we found four walls of red brick, just baked and pretty. There was no roof, but there was charcoal. We borrowed it and made a fire.

While part of the crew put in a new inner tube the rest of us heated irons which we found and, after knocking off the mud encrusted on the steering gear moving parts, thawed out the frozen bearings and got the car so it handled with its usual agility. We recommenced our journey warmed, good-natured and only a little delayed. We had been making good time all the morning, and were now somewhat used to the cold and felt the importance of our ride in this, the first 1908 car. But hardly had we started when there was symptom of fuel trouble. In other words, the engine stopped. Back into the brick yard, and we heaped more charcoal on the dying fire. Investigation showed that, during the tire repair, water which had been in the gasoline had frozen in the small filter-well below the carbureter float chamber and in the lower gasoline pipes.

Had Eaten the Last Sandwich and Pickle.

While we thawed out the frozen parts the afternoon became more gloomy with each departing minute. The sun had not been seen for hours, but we knew it was sinking behind the great streaked fresco of dull grey and ochre that told which was west. We were hungry. Long since we had eaten the last sandwich and the last dill pickle. We struck the brickmaker's house for supper and got it. Sitting around that kerosene-lighted table; our faces unwashed and streaming with melting mud; our clothes, eskimo-like in their rotundity; our furs steaming on chairs and making pools of water on the white kitchen floor; three men, the tired wife of one of them, and a little girl eying us curiously as they made a hesitating bluff at swelling the conversation, we almost became sentimental.

We figured over the chances of making Chicago that night. Ingenuous Fredericks called our attention to the fact that the hotel at South Bend was one of the finest in the West. The hint was laughed at, but finally acted upon. The road had been a tiring one to drive by day. It was a dangerous one to drive by night. At the Oliver we washed our abused faces with vaseline, and then went to bed—there to toss and dream for a few brief hours of snow and ice, punctured tires, brick yards and fleet miles.

The next day was not so arduous. The cold still fought our wraps and succeeded fairly well in reaching the channels of our sporting blood. But the sun was in and out among the cumulus clouds that stood in bold relief before the sky of baby blue which belied the weather. The roads were smoother now, for we were in a region which Hoosier farmers had macadamized.

We were welcomed at Hobart by a carful of Chicagoans, and we raced the '07 and the '08 over the glossy dangerous roads.

We Did Not Stop at Chicago.

We did not stop at Chicago nor even get out of the car, but started back for South Bend and reached it in mid-afternoon.

Immediately we fell to on the first square meal we had had since Detroit. In the evening we regaled the garage man and some of his friends with our experiences and with tales of other cross-country chases made by Waldon.

The following morning, as we lined up at the long counter of a restaurant with a "Never Sleep" sign, we knew that it was colder than either previous day. But we were by this time veterans, and we dashed out of South Bend with that renewal of form which always accompanies the beginning of the last lap. Waldon at the wheel must have felt it too. We in the tonneau raved about the frozen scenery along the St. Joe. We talked about previous and summer rushes over this Chicago-Detroit road and calculated the chances of smashing Waldon's round trip record of 22 hours 50 minutes, or 20 hours 36 minutes running time. We were gay and giddy. So excellent had proven the riding quality of the new springs that we were bumping over the rough roads as though on a cup race course. "Thank-ye-marms" we laughed at, but, of a sudden, we all hit the sky together and nearly missed the car when we came down. The cause was one of those combination cross ridges and depressions which some farmers imagine are necessary to prevent hill roads from washing out. A quick, sharp snap told of a broken spring, the left front one. The top leaf was gone near the axle clips. We drove along carefully for several miles until we espied Mottville, in Michigan, which has four houses, one blacksmith shop and a general store.

We welcomed the blacksmith shop and were welcomed by it. Mr. Mott was genial and a good smith. We needed strap steel to fix the spring and hunted through a pile of scraps beneath a bench until we found two pieces a couple of inches wide that would just serve our purpose. Mr. Mott laid them on the anvil, put the cutting hammer on the spot we indicated and with a savage blow of the knocking hammer cut the piece in two. He marked the other and raised the hammer, but stopped with it poised mid air, and ejaculated:

"By catnip! If them ain't those there gosh-blamed irons that Hi Smith brung in to fix up his plaw with!"

It was surely a "horse" on Hi, and it inspired us. That was the name of which we had been trying to think—true of the country, a name fitting this unnamed car which for three days had struck about as close to the heart of the countryside as you will ever get in an automobile. So we christened it—properly, with a half-empty bottle of chill-eradicator.

Backing out of the "Mottville Garage," a front wheel hub caught on the corner of the anvil and the aluminum hub cap was broken off. We stuck the garage tin cup over the end of the hub, wired it on and were soon away down the road.

It started to thaw about noon, and then to freeze again, so that we got a third layer of that conglomerate mass of chill thrown up from the road. We saw the places where, on Sunday, we had splashed mud all over the clean white sheets along the sides of the roads. We saw, in cold storage by the wayside, a chicken we had hit. We met a chicken that was alive until then. Afterward the speedometer stopped, but we did not learn the cause until we reached Detroit and looked at the front of the car. Then we found that the chicken had been traveling *in-cog*.

It was about 3 o'clock when we struck the center of Detroit and turned onto the boulevard for a final burst of speed. It was just as cold as ever, but we turned down our collars, primped a bit generally, and tried to look swagger as we drove to the factory home. There Waldon steered the car on the elevator, we were hoisted to the second floor, and ran, mud and all, into the experimental room, where nearly all the factory jokers gathered to pass comment on our appearance and ask leading questions concerning the weather, roads, and all the rest of it. It had been a great ride, but only the first. The car and three others, now being made, must go more miles—miles by the thousands—that qualities which are new may be tested on the rough road before they become standard. Even now is "Hiram" wallowing in the melting-freezing mud between Detroit and Cleveland under the guidance of Russell Huff, chief engineer—while Loomis sits in the warm drafting room figuring the price of a new pair of mittens on his wonderful guessing stick.

A GLIMPSE INTO ONE OF THE DEPARTMENTS OF THE IMMENSE NEW FACTORY OF THE GEORGE N. PIERCE COMPANY AT BUFFALO, THE PIERCE GREAT ARROW IS MADE.

BRIEF ITEMS OF NEWS AND TRADE MISCELLANY

W. H. Hotchkiss, president of the American Automobile Association, has just made his choice of an automobile for 1907. It is a Thomas Forty touring model.

The Fish Automobile Company of St. Louis, Mo., has given up the old McGirt foundry on South Center street and has moved to the Apex Manufacturing Company's building.

Several Fort Wayne capitalists are interesting themselves in the probable establishment of an automobile factory in that city to be run as a branch of the Buckeye Manufacturing Company, makers of the Lambert, at Anderson, Ind.

Pleased with past results, the Studebaker Automobile Company will fit every 1907 car with the Truffault-Hartford shock absorber, and has just completed the necessary agreement with the Hartford Suspension Company.

A receiver has been appointed to take charge of the affairs of the Clarke Automobile and Launch Company, of Jacksonville, Fla. The petition and bill filed by D. H. McMillan states that the company is hopelessly insolvent.

The exact location of the new factory which the Rainier Company will build in some Middle Western city has not yet been decided upon, despite reports to the contrary. Detroit was mentioned erroneously as having been the selection and a factory site acquired.

A new line of Oval horns in various sizes and of very deep penetrating tone has been placed on the market by the Automobile Supply Manufacturing Company, of Brooklyn. These horns have met with such approval that the company's two factories are working overtime to meet the demand.

The Pennsylvania Railroad Company is now experimenting with automobile baggage trucks for use in the Union station at Pittsburg. They are of extra heavy construction, and can be run by merely touching a button. Four are now employed at Philadelphia, and have proved such time-savers that the authorities think it is profitable to extend their use.

William H. Mead, manager of the Chicago branch of the Buick Motor Car Company, has leased the entire second floor of the Winton building, at Michigan avenue and Fifteenth street, and will use it for retesting and reshipping Buick cars to the out-of-town agents within his jurisdiction. Owing to the extension of business ground has been secured for the erection of a new building just south of the Franklin agency on automobile row.

Although the H. H. Franklin Manufacturing Company has just completed a five-story addition, it is apparent that more space must be secured, and arrangements are being made for obtaining additional room in other buildings in the near vicinity. The fact that the company must provide for the output of the commercial vehicle department is a consideration of the near future demanding additional space, which is not obtainable in the present factory limits.

A dealers' association is under formation by the automobile trade of the Newark, N. J., territory. At a recent

meeting the matter was thoroughly discussed and a committee appointed to consult the automobile trade and create an interest in the project. This committee consists of James W. Ward, C. S. Calvert, Frank E. Boland, Raymond S. Joo, W. H. Rickey, Frederick Hinni and John Beldon. All members of the automobile trade will be eligible for membership.

An involuntary petition in bankruptcy has been filed against the Four Wheel Drive Wagon Company, of Milwaukee, Wis., by three creditors, the Rundle & Spence Manufacturing Company, Siekert & Baum Stationery Company, and the Cream City Can Works. The petitioners allege that the company admitted its insolvency January 1, and signified its willingness to be declared bankrupt. The liabilities are said to be \$190,000, and its assets \$101,500. The company has not operated its plant for two months.

To visit the mammoth new factory in which the White steamers are made, Carl Page ran a "personally conducted" tour to Cleveland last week, in which twenty of his associates from the various White garages in the New York territory participated. The party chartered a private car which was attached to the Lake Shore Limited. Arriving in Cleveland in the morning, they were met by Walter C. White and a squadron of White cars, and were driven to the Union Club for breakfast. Practically the entire day was spent in inspecting the new factory. At the close of the day the White private car was attached to the Pennsylvania Limited, and the party returned to New York, more than ever impressed with the fact that they were a part of one of the great industrial organizations in the country.

Although his plan to create a convincing piece of advertising literature, extolling the Autocar, miscarried through no fault of his own, Fred P. Brand, general sales manager of the company, gained a new slogan. The Autocar is now "the car that takes you there and brings you back." Mr. Brand thought a booklet of testimonial letters from some Autocar users would be interesting, and communicated his ideas to the Autocar agents throughout the country. As a result, he was fairly overwhelmed with letters, more than 500 being received, making it out of the question to use all or even give a fair idea of the number sent in. So many of the writers concurred in calling the Autocar "the car that takes you there and brings you back" that the coincidence was striking.

In the new Columbia four-cylinder gasoline car with electric transmission, which attracted so much attention at the New York and Chicago shows, the revolving field generator serves the purpose of a clutch and transmission, the full driving effort being exerted by the engine directly to the driving pinion. The driving shafting extends along the center of the frame to the rear axle and three ball bearings are the only frictional parts between the engine and the rear axle. Owing to the elimination of the friction incident to the ordinary types of transmission, the hill-climbing

powers of this car are remarkable, and its adaptability to the varying conditions of road traffic, owing to the ease of control and simplicity of the entire apparatus, makes it considerably faster than its 45-horsepower rating would indicate.

NEW AGENCIES ESTABLISHED.

The Bartholomew Company has contracted with W. J. Brown, of Wellman, Ia., for the sale of the Glide in Washington and Keokuk counties.

A Haynes agency has been established in Brooklyn, N. Y., with the Borough Automobile Company, on Palmetto street, near Bushwick avenue.

The Chicago agency of the Detroit car has been placed with the Garfield Park Automobile garage, of 1891 West Harrison street.

The Eclipse Automobile and Construction Company has opened a large garage at Williamsburg, N. Y., in the former Empire Theater building. The agency for the Smith machine is located here.

The new California automobile, the Tourist, built by the Auto Vehicle Company, of Los Angeles, is now being handled in San Francisco by the Auto Company of California.

The latest addition to Philadelphia's automobile agencies is the Philadelphia Motor Car Company, now located at 236 North Broad street. The new company represents the St. Louis Motor Car Company, of Peoria, Ill.

Alfred Reeke, who for the past few years has been treasurer of the Orlando F. Weber Company of Chicago and Milwaukee, severed his connection with that concern on March 1 and has arranged to open an agency of the Wayne Automobile Company of Detroit, in Milwaukee.

RECENT BUSINESS CHANGES.

The Central Manufacturing Company, of Connersville, Ind., manufacturing buggy and automobile bodies, has voted an increase of its stock from \$50,000 to \$100,000.

The Toronto Automobile Company, located at 10 East Adelaide street, Toronto, has absorbed the Automobile and Supply Company (George H. Gooderham). The latter's garage and show rooms will be continued and the new premises closed up.

The partnership between Palmer & Christie has been dissolved and a new company formed under the title of the Martini Import Company. The directors are F. B. Palmer, C. F. Palmer and Joseph B. Freeman. Martini cars will be handled exclusively. The salesrooms of the company will remain as before at 239 West Fiftieth street.

D. D. Martin, general manager of the New York-Broadway Rubber Tire Company, located at 1186 Bedford avenue, Brooklyn, has removed his entire tire department to the second story of the building, and on the ground floor installed a complete line of accessories and supplies in charge of James F. Fairman,

recently with Smith & Mabley, Inc., of New York.

The O. H. Dietrich Company, Ltd., of Allentown, Pa., has been incorporated under the name of the Dietrich Motor Car Company, with garage and sales-rooms at 24 and 26 North Tenth street. Twenty-five thousand dollars is the fully paid in capital of the company. The officers are: President, G. J. Heintzleman; secretary and treasurer, O. H. Dietrich; directors, O. H. Dietrich, G. J. Heintzleman, Valentine Guldin and William T. Leh. Franklin, Cadillac, Buick and Thomas cars are handled.

PERSONAL TRADE MENTION.

Joe E. Yowell has been appointed manager of the Southern Automobile Company, of Nashville, Tenn.

F. C. Hoblitt, formerly of the Aerocar Company, Detroit, has become connected with the American Locomotive Motor Car Company, Providence, R. I.

Charles Coddington, for some time manager of the Southern Automobile Company, has left that concern to take up the management of the Capital City Automobile Company, of Atlanta, Ga.

James G. Heaslett, formerly of the Garford Company, of Elyria, O., has entered the employ of the Rainier Company, of New York, as chief engineer and designer.

THIRTY CARLOADS OF BUICKS.

What is probably the largest single shipment of automobiles ever made is depicted in the illustration herewith of one train load of Buick motors under shipment to the Pence Automobile Company, Minneapolis, Minn. There are thirty carloads in the train, consisting of ninety automobiles, the total valuation of which is \$112,500. Big as it is, the shipment constitutes less than one-third of the total number of cars ordered by the above named company, their total allotment for the season being three hundred, made up of two hundred and fifty two-cylinder models and fifty four-cylinder models. The Buick Motor Company factories are all working to their full capacity, and extensive building operations are under way at Flint which will double the capacity at that point. Among other important additions there is to be a new drop forge plant and a plant for malleable castings. These will be ready in time for the 1908 business.

TRADE PUBLICATIONS RECEIVED.

The latest folder from the H. H. Franklin Manufacturing Company, Syracuse, N. Y., describes type G Franklin runabout, a smart-looking little twelve-horsepower machine which, as the folder has it, "suits the highest runabout ideal like a glove."

From the Berkshire Automobile Manufacturing Company, Pittsfield, Mass., is to hand a sixteen-page handbook on that firm's Model D touring car. The history of the machine and its distinctive features are related in text and cuts, gotten up in the neatest style.

Garvin motor-driven machine tools are illustrated and described in the unpretentious little booklet issued by the Garvin Machine Company, of New York City. The list here given is not exhaustive, but it shows the most important models handled by this firm in plain milling machines, vertical spindle milling machines, hand drilling machines, Garvin profilers, die slotters, automatic tapping machines, and hand lathes.

There is a considerable amount of useful information in the booklet bearing as its title "Clinchers" and issued by the Continental Caoutchouc Company. It gives sizes of tires in American and metric measurements, prices, history of the Continental firm in its native city of Hanover, Germany, and its doings in its adopted land, as well as a list of agencies throughout the world. There are some useful hints on the care of tires, weights which various size tires will carry, and information on the making of temporary repairs. Any automobilist can secure a copy of the booklet on request to the Continental Caoutchouc Company, 2100 Broadway, New York, or their various branches.

There is some interesting reading in the neatly produced booklet by Frank P. Illsley on the "Six-Cylinder Situation in Europe." It contains a large number of clippings from European automobile journals, and from the European correspondents of American motor papers, on the six-cylinder situation. For the man who has not had time to study the six-cylinder proposition and who is not well acquainted with what is being done in this line of motor construction, the booklet provides useful up-to-date information. The Stevens-Duryea Company has something to say on its share in the six-cylinder movement, but the compiler of the brochure has sought rather to give information on the subject in general than beat the big drum for any one firm.

The "International Girl," a copyrighted reproduction from the original painting by Abbey Alston, is the attractive head-piece of the International Rubber Company's (Milltown, N. J.) publication on tires. The literary work of the booklet is a setting forth of the qualities of International tires and their methods of construction. A price list of International tires is included in addition to a table showing the carrying weights for different size tires. From the same company has been received a life-size reproduction in colors of the painting—the "International Girl." It is a well-produced piece of color printing, and doubtless members of the trade will be glad to avail themselves of the offer of the International Rubber Company and obtain the hanger on sending twelve cents in stamps to cover postage.

ELCO MOTOR BOATS.

Probably there is no better known make of motor boats along the entire Atlantic Coast from Maine to Florida than those which bear the "Elco" mark. Not being wedded to any particular school or system, their builders, the Electric Launch Company of Bayonne, New Jersey, are impartial advocates of steam, gasoline and electricity and are well known as the creators of exclusive designs using each power, a large number being in service round about the waters adjacent to New York. Their name has become more closely associated during the past few years with the speed type of boat—more popularly styled the automobile boat, in that it has been designed with a view to rendering about the same class of service on the water as the automobile does on land. These boats are built in sizes ranging from 26 to 40 feet over all, are equipped with the standard multi-cylinder type of automobile motor of the latest design and of powers sufficient to give speeds ranging from 15 to 30 miles an hour. The engine is placed forward under a hinged hatch, permitting of ready accessibility to every part and leaving the entire cockpit free for seating room, which is generally taken advantage of to use wicker arm chairs. This firm has become even better known as builders of speed launches and large cruising yachts, after the plans of some of the best-known yacht designers—boats that have become famous for their performances in contests or for the luxury and ingenuity displayed in their arrangements and equipment. They are about the only builders who have made a specialty of electric launches, to which they have devoted considerable of their attention for quite a number of years.

RECORD SHIPMENT OF BUICKS EN ROUTE FROM FACTORY AT FLINT, MICH., TO MINNEAPOLIS, MINN.

INFORMATION FOR AUTO USERS.

Tire Chains.—The Johnson Tire Chain is designed to supply the demand for a light weight and low-priced device that will prevent loss of traction in snow, sand and mud. There are no side chains. The other members, however, hold the traction members in operative position, each being a unit, held in position by the spoke. This construction does away entirely with any trouble resulting from the failure of any one part. Owing to

the peculiar method of fastening to the spoke, all side and other slipping is effectually prevented, giving a unit structure that is self-retained in such a manner that no part is lost when any member is worn through by use. This is the only chain traction device that can be readily applied without either jacking up or moving the car, thus making it a very simple matter to apply in emergencies, such as being hung up in the mud, snow or sand spot. It has been shown by actual practice that six of these chains on each rear wheel give sufficient traction for all ordinary work, although twelve can be used, or one to each spoke. As they are easily and quickly applied, they may be carried in the tool box, and used only when necessary, in this way saving much wear, and removing every excuse for leaving the same on wheels when the roads are good. It is made in sizes adapted for all tires from 2 1-2 to 5-inch, and, as it is designed to fit loosely, does not injure the tire.

C. F. Tucker, Hartford, Conn.—Dust and grit are such penetrating substances that they will find their way into any unguarded oil hole on the car, no matter how small it may be, nor how well pro-

CROSS SECTION OF TUCKER VALVE.

TECTED it appears to be. Moreover, the rapid motion, particularly of any revolving parts, tends to throw the oil out, so that it is impossible to keep a supply of

oil on such parts. The necessity for continually digging mud and sand out of such holes every time it is necessary to oil them, is a nuisance, and to avoid it, as well as to protect the bearing, a device such as the Tucker oil hole cover and cup, which has been on the market a number of years, should be employed. As will be seen in the cross-sectional illustration, these cups screw firmly into the oil hole and are provided with a filler vent at the side near the top, which may readily be opened by revolving the top with a screw-driver. They hold sufficient oil to lubricate such bearings as they are required for many hundred miles, and not only stay where placed, but add to the appearance of the car.

Cushion Springs for Autos.—One of the first firms to enter into the manufacture of cushion springs for automobiles in this country was the Charles Wing Company, of Amesbury, Mass. The company is now making a specialty of the "Wing" cushion spring adapted for all descriptions of vehicle seats, but specially suitable for automobiles. The cushion spring is strongly constructed, makes a very easy riding seat, and stands up under hard usage and heavy strain. A full line of auto trimmings is carried.

Improved Oil Can.—In addition to the barrels, half barrels, and five and ten-gallon cans of lubricating oil, the A. W. Harris Oil Company has now on the

market a very desirable one-gallon decorated package which has what is known as the coalhod spout with screw cap. This addition, the usefulness of which will be appreciated by all who have filled an oiler from a large can, is also used on the five and ten-gallon cans. The one-gallon package is particularly handy for both the individual user and the retail trade.

C. F. Iszard, Germantown, Philadelphia, Pa.—Despite the great number of speed and distance-recording devices that has been placed on the market during the past few years, none had been devised to produce a continuous record until the appearance of the Recording Auto Speed Meter, the mechanism of which is illustrated by the accompanying illustration. The operating mechanism is the same as that ordinarily employed, i.e., a striker revolved by one of the front wheels and a flexible shaft. A clock movement is supported on a stationary shaft, around which it revolves, carrying a drum holding the record sheet. The clock is geared to revolve four times in twenty-four hours, and is so mounted that each revolution causes the record chart to move horizontally a quarter

inch, making the record of each period of six hours entirely distinct. Mounted in the center of the gear is a shaft, having at its end a cam engaged with a pen lifter, so that at the completion of each mile the pen drops and records it. This gear can be disengaged and turned by hand so that the machine may be set at

ISZARD RECORDING SPEED METER.

the starting point whenever desired. The fountain pen holds sufficient ink for a week's running and is of non-corrosive metal; it is suspended on a flexible band, so that no amount of jarring causes it to make a false record or spill the ink. The construction throughout is made very rigid, so that the jarring cannot disturb the clock movement or derange any of the mechanism. The inclosing case is either of mahogany or aluminum and its outside dimensions are only 5 by 4 by 3 inches, requiring but a small space on the dash. It is the invention of C. F. Iszard, and is patented.

An Improved Breast Drill.—Quite a number of new and valuable features have been embodied in the improved universal breast drill, placed on the market by Patterson Brothers, 27 Park Row, New York. It has a chain feed attachment, operated by the supporting handle, allowing pipes and similar articles to be drilled with ease. It can be ad-

IMPROVED UNIVERSAL BREAST DRILL.

justed to any angle, making it indispensable for automobile working. The sweep of the handle can be adjusted, and when limited space does not allow a full turn of the handle the ratchet is used. It is provided with two speed gears.

THE AUTOMOBILE

BOSTON, March 13.—New Englanders are clannish. They prefer to buy and select their autos at their own show. This they have been generously doing since Saturday night last and will continue to do until Saturday night next. No such complete line of American automobiles—a few foreign makes are intermingled—has been placed on view at any previous show of the season. New York, through force of circumstances, had two shows on different dates, and while Chicago contained both the sheep and the goats—separate them according to your own ideas—its total fell short of the number housed in the elongated Mechanics' Building and the annex-serving Horticultural Hall, several blocks up Huntington avenue. The thrifty resident of the Old Bay State, the wooden-nutmegger from Connecticut, the clam-digger of "Little Rhody," the man from the Green Mountain State, he who hails from the Granite-ribbed commonwealth, and the "Down-Easter" from Maine are much in evidence, and from beginning to end the exhibition has the substantial hallmark of New England embedded in an unmistakable manner.

Underneath the Old Apple Tree.

"In the shade of the old apple tree" are the autos picturesquely displayed, and while there is none of the grandeur of the Garden show nor much of the admittedly harmonious dressing of the Coliseum, and thankfully an absence of the dark and dusty draperies of the Palace exhibition, the general effect is

pleasing and novel, suggestive of the coming of Spring and inviting to the owner and owner-to-be and typical of the truly American atmosphere of New England. Here one finds the conservative patriotism that blends reassuringly into the foundation of our great country, and the man whose blood has a Puritan tinge has been quick to appreciate and appropriate the motor-driven vehicle and the blessings that follow in its trail.

Before one reaches the orchard of the main hall he must needs pass through a gradually widening trellised garden; en route his pathway is bedecked with rambler roses, many of which contain cores of electricity; the autos are partially fenced in here and there; shining brass and nickel gleam and glossy enamel reflects so brightly that the fair sex cannot resist the mirror invitation to see if their hats are resting at the proper angle. Then one bursts into the grand showroom of the apple-blossomed decorations—and wishes, mayhap, that Manager Chester Campbell had bought just a few more apple trees.

Anent the Buying of the Apple Trees.

There was some difficulty, however, in the buying of these apple trees. Manager Campbell thought that he had an option on an orchard, but a farmer's wife who heeded not the mercenary spirit of her liege lord and master cancelled the deal at the eleventh hour. A snow-blown hunt for more apple trees became necessary, and it required some diplomacy on the part of those entrusted

LOOKING TOWARD MAIN ENTRANCE.

with the errand to convince the honest plowman that in selling frozen and rootless trees he was not guilty of obtaining money under false pretenses. At first he looked upon the buyers as if in doubt as to their sanity when they told of their plan to have the trees blossom before Spring. But the price was made, the trees sawed and brought to town, and lo! they are in full blossom for the show.

More Different Autos Than Ever Before Seen.

One hundred and twenty-one different makes of automobiles are scattered about the Boston show, and apparently not a single car of any importance is missing. Up in the galleries—sandwiched in with accessories galore—down in the basement with the motor boats, and up the avenue in Horticultural Hall are on view automobiles of all kinds—gasoline, electric and steam, from eight-cylinders down to one, with four and two-cycle engines, water-cooled and air-cooled, those which have gained the esteem of the buying public and those which are participating in

becoming more pronounced that there is some planning which may make the A. L. A. M. show a November or December event in Madison Square Garden, and the same line of conversation argues for December dates for the N. A. A. M. in Chicago's Coliseum. The A. M. C. M. A. and A. C. A. combination has an eye to the possible revised situation, and the representatives of the two organizations are hereabouts, ears to the ground and watchful of developments. While the Boston show is not national, national figures in the industry are numerous, and the talk of the hotels and clubs this week is automobile from early until late. Now and then the much-discussed Selden patent comes in for some attention, and the chances of a decision before next Winter's shows are weighed more carefully than would have been the case several months ago.

Revolutionizing the automobile industry is not quite as easy as it was a couple of years ago, and one hears less of these assertions as the motor-driven vehicle grows older. The New Englander has been something of an inventor in his day, but the

PAUL REVERE HALL, WHERE THE EXHIBITS OF THE VARIOUS POPE FACTORIES ARE SHOWN.

their débuts. It is an exhibition that tells of an industry's wonderful progress and its assured future.

A Dealers' Show Is Boston's Exhibition.

Successful and as big as it is, this New England exhibition is a dealers' show, for dealers and by dealers, for the purpose of educating the thousands who come in vast degree to learn about something in which they may never have an active part, except some day to be a passenger on an autobus. That opening night snowstorm of complimentaries, which is a Boston idea exclusively, brings to the show a good-natured mob, which peacefully edges its way into Mechanics' Building, congests the aisles, gets a fleeting glimpse of the cars, and emerges into the night, wondering where the money comes from which buys duplicates of those luxurious vehicles. Much good may result from this invasion of probable non-buyers; certainly no harm can result in their attendance.

Earlier Dates for Garden, Coliseum and Boston?

Of the big shows—and, though 'tis a dealers' affair, Boston is included—this one comes the latest, too late, say some of those most interested. But how to have it earlier, with Chicago holding forth in February, is an unanswerable problem. Talk is

automobile has been, and likely will continue to be, a product of gradual development, and so he has not brought forth anything that has disturbed the steady line of progress. While there are new cars in the Boston show, none of them will disturb the equanimity of the established maker. However, several newcomers should bid successfully for a permanent place in the industry. Accessories furnish a prolific field for inventive minds and not a few excellent new things are uncovered for the first time.

Boston's Auto Clubs Entertain the Trade Visitors.

At the clubhouses of the Bay State Automobile Association and the Massachusetts Automobile Club the visiting tradesmen are being made welcome, and it so happens that most of them are members of A. A. A. clubs in other cities. The national body has an excellent system of reciprocal club privileges, the understanding of which is a convenient asset during show time in the various cities.

The Wachussetts Automobile Club to-night held its annual dinner at the Parker House, President Chase presiding. First Vice-President L. R. Speare, Secretary F. H. Elliott, and Director A. G. Batchelder were A. A. A. guests of the occasion. The program of festivities was admirably arranged.

SOME OF THE NEWCOMERS UNCOVERED AT THE HUB

FACTORY organization and the execution of plans for the building of a high-grade car are not matters that can be perfected at short notice, so that it is unusual to see a car that only made its debut a year ago, having all the earmarks of the product of a number of years' standing. This is the case of the Shawmut, which made a somewhat belated appearance at the Boston show last year, and is now being exhibited in all its glory. It is one of those rare instances in which a new car represents the work of its own builders from beginning to end, with the exception of such essentials as wheels and tires, that lie entirely in the domain of the specialist. What is even more unusual is the fact that, in this case, no attempt whatever has been made to rush a car on the market; the most painstaking effort has been taken to make every part of it as close an ap-

r. p. m. The carbureter is of special design, made in the home factory, while ignition is of the high-tension type, using a Simms-Bosch high-tension magneto as the source of current. Lubrication is entirely automatic and the fuel feed is of the pressure type, the gasoline tank having a capacity of 25 gallons, a tank gauge and hand pump being mounted on the dash. Control is by means of the usual hand spark and throttle levers on a stationary sector mounted over the steering wheel, beside which an accelerator pedal is provided.

One of the original features of the car is to be found in the clutch employed. This is of the multiple-disk type and is composed of 51 disks, but the latter, instead of having perfectly flat contact surfaces as is generally the case, are alternately of concave and convex surfaces. By removing 11 nuts, the entire

THE EXHIBIT OF THE SHAWMUT MOTOR COMPANY WAS COMPLETE, EACH TYPE BEING SHOWN.

proach to perfection of design as possible, and in the very highest grade of materials obtainable.

The statement of the makers that the Shawmut is *built*, not manufactured, serves to throw some light on the methods used in its construction, and is directly in line with the avowed purpose of the organizers of the company that is its sponsor, to build the best car possible irrespective of cost. No attempt has been made to produce a revolutionary design or a car that would in any way bid for public favor, through its bizarre or unusual features. The result is a car that embodies the very best ideas of engineering schools on both sides of the Atlantic, together with a number of ingenious original features. Four models are now turned out, the same chassis being employed as the groundwork of all of them. This is equipped with a 40-horsepower, four-cylinder motor mounted on a pressed steel frame of the usual channel section, and of the drop type. The motor cylinders are of the best grade of iron, cast independently, and their dimensions are 4.3-4-inch bore by 5.1-2-inch stroke, the engine developing its rated capacity of 40 horsepower at a normal speed of 1,200

clutch may be removed without disturbing either the flywheel or the transmission. A sliding-gear type of change-speed gear, operating on the selective plan of gear-changing, constitutes the next step in the transmission, the gears of which are all of Krupp steel, while the shafts run on Hess-Bright ball bearings of liberal proportions, as, in fact, is true of every other moving part of the car, including the crankshaft of the motor, no less than 47 bearings of this type being required in all. The change-speed gear provides four speeds forward and a reverse, the direct drive being on the third. The front axle is a one-piece drop forging of Krupp steel, and the rear axle is also of imported steel from the same makers. Suspension is of the standard type, using semi-elliptic springs front and rear, the former being 40 inches long and the latter 54 inches.

As an instance of the painstaking care used in the design and construction of every part of the car, it may be mentioned that multiple keyways of no less than six slots are used on all fastenings outside of the motor, and the manufacturers' confidence in their product is well demonstrated by the wording of their

THE CHASSIS OF THE BAY STATE FORTY SHOWS A STRONGLY BUILT AND A STURDY LOOKING CAR.

guarantee, which is to the effect that they will replace "without question as to cause," any breakage occurring within one year from date of purchase, when not due to collision or other external disaster.

A rather noticeable feature about Model A, known as the 40-horsepower roadster, is the fact that it is equipped with wheels of larger diameter on the rear than in front. These are 36 by 4 rear and 34 by 3 1-2 front, Michelin tires being the standard equipment, except where otherwise specified by the purchaser. The drop frame gives the car a pleasing appearance and keeps the center of gravity down, though permitting of 9 1-4 inches clearance. Two sets of brakes are provided, both centered on the rear axle, the foot or running brake operating an internal expanding brake on a special drum, and the hand brake, or emergency, operating a constricting band on the same drum. With full equipment, the roadster tips the scales at 2,675 pounds. The wheelbase is 108 inches and the tread standard. Seats for three are provided, the body being of aluminum and wood and of a special design built at the home factory which turns out all the bodies used on these cars. To protect the mechanism from beneath, a close-fitting sheet-steel pan extends from the radiator to the rear of the transmission case and is made so as to be easily removable.

The touring car, known as Model B, differs from the roadster or runabout, chiefly in those points necessitated by the use of a longer body. For instance, it has a wheelbase of 112 inches

and is equipped with the same size wheels front and rear, larger tires being used on the latter; these are 34 by 4 and 34 by 4 1-2, the car in complete running order just reaching the 3,000 pound mark. The body is wood and aluminum, designed along the pleasing lines so strongly favored by Continental body makers—in other words, what is usually referred to as a straight line type. It is finished in ultramarine blue with black trimmings set off by light blue lines, the metal work and lamps all being nickel plated, the roadster being finished in white with black upholstery and also having nickel-plated trimmings. Model C is a 40-horsepower town limousine on a 108-inch wheelbase. It has a seating capacity of seven passengers and is finished the same as Model B, with the exception that the metal trimmings are silver-plated. The remaining model of the line, Model D, is a touring limousine with a seating capacity of eight passengers, and has a 126-inch wheelbase. Nothing that could conduce to the greater comfort of the passengers has been omitted, such as electric lighting, annunciators, mirrors, toilet facilities and the like. The stock finish of Model D is the same as Model C, but as the factory builds all its own bodies, the purchaser is given an option on any finish desired. The various models list at \$4,750, \$5,000, \$5,750 and \$6,500, in the order named.

The New "Bay State Forty."

As its name indicates, this is another home product of the New England soil. It has not been the object of the designers and builders to bring forth a new addition to the line of radical and out of the way cars, but rather to profit by the experience of those who have had to pay for costly mistakes of this kind in the past, and that is what they have done by taking advantage of the established trend of standard practise in every respect. The motor is of the four-cylinder type, the cylinders measuring 4 3-4 by 5 inches. They are cast in pairs and the motor is rated at 40-horsepower, which it develops at a moderate normal speed. The carbureter is of a special type with double throttle, and no less than three systems of ignition are installed. Two of these are entirely separate and independent, one taking current from a set of accumulators and the other from a magneto of the high-tension type working through a single coil and separate distributor. This latter system is duplicated by the use of a second distributor. For lubrication, a force-feed oiler of the mechanical type is employed, a sight-feed being placed on the dash. Control is by means of the usual spark and throttle lever on a stationary sector mounted over the wheel. The power plant entire is suspended on a three-point support employing a ball and socket joint as the third point.

To transmit the power, the first step consists of a multiple-disk type of clutch provided with cork inserts and having a ball-bearing end thrust. The change-speed gear is of the sliding

HOLMES TOURING CAR, WHICH IS BUILT IN EAST BOSTON.

changing is effected by the straight or progressive method, the pinions being of special steel and designed with liberal faces and easy entrance to avoid clashing as much as possible. Final drive is by propeller shaft and bevel gear, a bevel differential being employed.

The foundation of the chassis consists of a pressed-steel frame of the standard channel section, suitably reinforced by cross braces and gussets with the usual I-beam drop-forged front axle; semi-elliptical springs are used front and rear. Two sets of brakes are provided, both of them centered on the rear hubs and of the standard internal expanding and external contracting type, operating by pedal and side lever respectively. The gasoline tank has a capacity of 18 gallons, beside which there is a reserve tank holding two gallons. With a touring body having a capacity of seven passengers, and full equipment, the car tips the scales at 2,800 pounds, which is unusually light for one of its power and size. The wheelbase is 122 inches and the tread standard, 34 by 4-inch front and 34 by 4 1-2-inch tires being fitted. The new car lists at \$3,750, with standard equipment of headlights, horn and tools.

An Electric Among the Newcomers.

Not the least prominent of the newcomers to be found at the show is the Bailey electric phaeton, made by S. R. Bailey & Co., Inc., of Amesbury, Mass. While new to the automobile field, this company has been known throughout the country for the past half century or more as builders of fine carriages, so that they are not altogether new to the making of pleasure vehicles. Few, if any, makers of electric vehicles build them entire, or to anything like the same proportion that is usually manufactured by the builder of gasoline cars, so that the carriage work is a correspondingly more important part of the make-up of an electric, and for this work, the new makers are, as already stated, exceptionally well equipped. In placing the Bailey electric victoria phaeton on the market, their object has been to produce a car for general city and suburban service, and one which, for both pleasure driving and utility, should meet the demands of the most exacting.

The sills of the frame are of patented construction and consist of a composite structure of steel angles and steel plate, which, while very rigid in one direction, possesses a certain amount of flexibility in others. It permits of the use of a very light and yet strong frame. The latter is hung upon four semi-elliptic springs, 40 inches in length. The motor has been specially designed for this service by the General Electric Company, and is wound to run at a potential of 60 volts. Both the motor and differential countershaft are hung in a flexible frame, preventing loss of alignment. From the motor to the differential countershaft, the drive is by means of a Morse silent chain, and from the countershaft to the rear wheels by roller chains, all of which are tightly enclosed in dustproof aluminum cases. The standard battery equipment consists of 30 9-N. P. Gould cells, but the purchaser may exercise his option in this respect and have any battery he prefers installed. The controller gives four

SIDE VIEW OF BAILEY ELECTRIC VICTORIA PHAETON.

speeds forward, the maximum being 18 miles an hour, the purchaser also being given the option of a higher speed if desired. Two reverse speeds are provided. Steering is by wheel of special Bailey pattern, the steering column passing through the dash at a point that clears the footboard enough to give plenty of foot and knee room; the steering column is arranged to swing aside to facilitate entrance and exit. The control lever is placed on top of the steering wheel and is interconnected with the brake, so that putting on the latter shuts off the power, and the latter cannot be applied with the brakes on. Three of the latter are provided, two band brakes on the rear wheels and one on the motor, giving a high factor of safety in this respect.

The running gear consists of Bailey oil-bearing, "pivot" axles, which have been a feature of their runabouts for the past ten years. The wheels are of an improved artillery pattern, 34 inches in diameter and carrying 3 1-2-inch pneumatic tires. The electric headlights and tail lamp are from special designs by Gray & Davis. With the standard battery equipment, the car is capable of running 40 to 50 miles on a single charge, and if desired by the purchaser, this may be increased 50 per cent. The car lists at \$2,000, a detachable rumble seat being provided at \$100 extra.

Two Types of the Holmes Shown.

Two different models of the Holmes cars are shown, one of them representing quite a departure from standard practise, in that it is equipped with a double-opposed horizontal motor placed parallel with the frame, but in front and under a bonnet. This construction is facilitated by the use of a friction drive bearing directly against the flywheel of the motor. The dimensions of the motor are 5 by 5 inches, developing 22 to 24 horsepower; ignition is of the high-tension type, using dry cells as the source of current, though provision is made for a magneto. The face of the flywheel of the engine is given a copper alloy surface and comes directly in contact with the fraction member of the driving gear mounted on a shaft lying parallel with the frame and not type, giving three speeds forward and reverse, the shafts being mounted on annular ball bearings of liberal dimensions; gear

THE LATEST ROSS RUNABOUT STEAMER LOOKS GOOD.

CHASSIS OF HEYMAN 5-CYLINDER CAR--A NEW COMER.

ATLAS AUTOMOBILE STREET SPRINKLER.

far from it. This friction member is arranged to slide along its shaft, control being by means of the usual side lever, all wear coming upon a special friction material which the makers of the car guarantee to be good for 5,000 miles and which can be replaced at a cost of \$3. The flywheel and friction member are brought together by means of a pedal-operated lever. Final drive is by means of a propeller shaft, fitted with two universal joints. The gasoline tank is placed under the front seat and holds 15 gallons. Tires are 30 by 4 inches. With the standard equipment, the car lists at \$1,350 as a five-passenger touring car, or at \$1,200 as a runabout.

The other car shown by the same builders is known as the Holmes Model H, and is a four-cylinder, 24-28-horsepower car of standard design. The motor cylinders are separately cast, their dimensions being 4 by 4 inches. The valves are oppositely disposed in chambers and mechanically operated, the ignition timer and pump being placed on the forward face of the crankcase and all timing gears thoroughly enclosed. The Holley carbureter is fitted, but if desired by the purchaser, an option on any other standard make will be given. The crankshaft is of high-carbon nickel steel, forged and cut from a billet. The crankcase is a special aluminum alloy, the supporting arms being made fast to the upper half which carries all the bearings, thus making the lower half serve merely as an oil pan. Ample inspection plates are provided and are held in place by thumb nuts so that no wrench is required for their removal. Ignition is of the high-tension type with dry cells, though provision is also made for a magneto on the engine. The transmission of this car is of the same friction type as that already described as being fitted on the Type S, except that it is differently arranged; the entire power plant carrying the flywheel friction disk is supported on a movable sub-frame under the bonnet, final drive being by means of double side chains. The clutch or friction engaging device is operated by means of a foot pedal, speed changing being accomplished by the usual side lever. As a five-passenger touring car fitted with 32 by 4-inch tires, the Type H Holmes lists at \$1,750, and as a two-passenger runabout, at \$1,500, the usual equipment of lamps, tools and the like being provided. While new in the automobile building field, the Holmes Vehicle Company, East Boston, Mass., are old builders of machinery, having had forty years' experience in this line.

The Heyman Car a Radical Departure.

This car may well be termed to represent the greatest mechanical novelty that the show brought forth. The power plant consists of a five-cylinder, four-cycle motor, the cylinders of which are placed round the circumference of a circle with their axes parallel to each other, the nest of five being surrounded by a single sheet-brass casing or waterjacket. The cylinders, which measure 4 1-2 by 5 inches, are ground internally and externally, all joints being conical and ground to fit, in order to obviate the

use of packing. The engine is a sort of straight-line type, the connecting rods all working on a single crank. The rods have hardened ball ends and work in hardened sockets; they travel in practically a straight line, as their maximum deflection is but 5-16 of an inch. The pistons are ground and fitted with four eccentric rings. Alternate cylinders are fired in sequence, five impulses taking place during every two revolutions of the crankshaft. The explosions are thus 140 degrees apart, lapping each other by 30 degrees, so that a constant turning effort is produced. Both the suction—mixture being supplied by a Schebler carbureter—and the exhaust of all five cylinders is handled by a single, conical, rotary valve, while an automatic oiler mounted directly on the engine takes care of the lubrication. The pump and ignition timer are also attached to the engine and are driven by hardened spiral gearing, ignition being of the high-tension type through a single coil. The engine is placed forward under the bonnet at an angle from the horizontal to bring it in practically the same plane as the driving shaft.

The change-speed gear is also of an unusual type, using roller clutches giving any desired ratio of speed between the engine and the rear wheels, so that with the lever in its minimum position the engine will run at 500 r. p. m. and only rotate the driving wheels once per minute, while in its normal position, 1 1-2 revolutions of the engine produce one turn of the rear wheels, any ratio between these two extremes being available. A sector giving 20 positions or speed changes is provided. Final drive is by cardan shaft with two universal joints of improved design. The frame is of the usual pressed-steel, channel-section construction, running on 34 by 4 1-2-inch wheels with a 108-inch wheelbase. Tread is standard and all on the car weighs 3,000 pounds, suspension being by means of semi-elliptic springs, 36 inches in front and 48 inches in the rear. The car is given a distinctive appearance by the use of a Whitlock radiator of round form. With the usual equipment, consisting of head and tail lights, tools, etc., the Heyman lists at \$4,000.

First Gasoline Sprinkler Shown.

One of the novelties that attracted a great deal of attention was the sprinkling wagon with its business-looking steel tank at the exhibit of the Knox Motor Truck Company's stand, in Horticultural Hall. This type of commercial vehicle is not exactly new, as it has had forerunners in the electric field, but it is the first of its kind to be driven by a gasoline engine, and further interest is added by the fact that this of the two-cylinder, two-cycle type specialized by these builders in their heavy trucks. The tank has a capacity of 800 gallons and can sprinkle a swath 24 to 28 feet wide, which, with its speed of 10 miles an hour, will give it the capacity of no less than four of the old-time horse sprinkled wagons; in other words, the one man in charge of this machine will be able to accomplish the same amount of work as four drivers and wagons and eight horses. The new automobile sprinkler has been ordered for use on the Revere Beach Reservation during the coming summer.

A New Tire Among the Accessories.

The only new thing to be uncovered in the field of tire making is the Butler tire, which is neither a pneumatic nor a solid, nor, on the other hand, a spring wheel, though in some respects it partakes of the characteristics of all three. Fastened to the felly of the wheel is a slotted rim of peculiar construction in that it provides accommodation at either side of the felly for two series of helical wire springs, which have members extending across the rim at certain intervals all the way round. The tire itself is a cross between a clincher and a detachable type of shoe and is made fast by means of a number of bolts passing through the felly. This holds it to the rim and it is supported above by the spring members referred to. The new Butler tire is being placed on the market by the Massachusetts Automobile Company, Church street, near Park Square, Boston, a concern that is one of the largest dealers in second-hand cars at the Hub, if not in New England.

THE BARKER-WHITE SYSTEM OF UTILIZING ALCOHOL

AS is probably well known to the majority of autoists, the use of alcohol as a fuel for the internal combustion motor is something that has occupied the attention of scientists and engine designers for quite a number of years past. Of course, this has been true only of the Continent, and no time has been devoted to the subject here prior to the passage of the recent legislation exempting denatured alcohol for industrial purposes from taxation, for the very natural reason that, even had it been greatly superior to other liquid fuels, it was not practical from an economic point of view owing to the tax. During the decade or more that has elapsed since the inauguration of the policy of Government support that has been so consistently adhered to in Germany, the alcohol motor has been made the subject of exhaustive experiment and investigation, and there are at present thousands of motors of various kinds used abroad with alcohol as a fuel. Those who are at all familiar with the subject are aware of the result; success with alcohol as a fuel has only been attained by the use of high compression, a long stroke and a slow speed—factors all of which contribute to the design of a motor whose weight per horsepower is unduly high, and in consequence unsuited to the needs of either automobile or light marine work in the motor boat.

Alcohol and Acetylene Compared.

Alcohol is a definite compound, and its chemical composition is such as to preclude its burning sufficiently fast to permit of its use in a high-speed motor with any great degree of efficiency. By weight it consists of oxygen 34.8; hydrogen 13.0, and carbon

52.2; these figures are approximate and refer to pure alcohol which is commercially impractical. The ethyl or grain alcohol of commerce seldom contains less than 10 per cent. of water. This not only lessens its calorific value as compared with other fuels, but doubtless also tends to retard the rate of flame propagation, owing to the presence of the steam generated. An equally great objection to its use on the automobile is the length of time required as well as the necessity of heating in order to start, and the high temperature which must be maintained both in the vaporizer and the motor in order to realize anything like the maximum efficiency.

Acetylene, on the other hand, is a compound consisting of equal parts of carbon and hydrogen, and for that reason is found to be at quite the other extreme. In combination with 14 to 15 parts of air its explosion is so rapid and the pressures realized so great, that detonation more accurately describes its action. Although 12-2 volumes of air are required to burn it, and the most effective mixture is that already referred to, mixtures as weak as 18 to 1 will ignite readily, and in the experiments made by Grover even so lean a mixture as 30 to 1 showed an initial pressure in the cylinder of 180 pounds to the square inch, with a compression of but 30 pounds. Grover continued his investigations of acetylene as a fuel over several years and gives the characteristics of the explosion of a mixture of acetylene gas and air as follows: Great rapidity of flame transmission, a pressure of 120 pounds to the square inch being realized in .02 of a second from an explosion at atmospheric pressure; high combustion temperature and extraordinary amount of energy de-

ENGINE AND GENERATOR TESTING APPARATUS USED IN EXPERIMENTING WITH ALKOETHINE.

MESSERS. BARKER, WHITE AND TRACY DEMONSTRATING ALKOETHINE.

veloped, indicating that the thermal efficiency attainable with a motor using it as a fuel would be greatly in excess of any other known.

The Barker-White Combined System.

The foregoing data is given merely to show the status of these two substances as fuels for the internal combustion motor when the matter of investigating the possibility of using both in combination was first attempted by Thomas L. White, who has been granted a patent on a system of this kind, jointly with F. W. Barker (No. 839,798, Dec., 1906). Numerous experiments had been made with alcohol engines and a great many motors using this fuel had been in use over an extended period, their characteristics already having been referred to, and the possibility of using acetylene as a fuel had also been investigated at some length, though without any practical outcome so far as the actual building and commercial use of such a motor was concerned, when Mr. White conceived the idea of taking advantage of the extreme characteristics of both by combining them.

This he has done in what is known as the Barker-White system of utilizing a combination of these fuels, and though still in the experimental stage so far as the design of the apparatus to be ultimately employed is concerned, more than enough has been accomplished to demonstrate beyond a doubt what great promise a commercially practical method of effecting this holds forth. As is well known, the method of producing acetylene gas is by bringing water in contact with carbide of calcium, and this has been taken advantage of in connection with the fact that commercial alcohol always contains a certain percentage of water, thus affording a means of regulating the character of the mixture, as passing pure alcohol over the carbide would not affect it. Anhydrous alcohol is, of course, not an impossibility, but the process of distillation required to entirely free it of water is so long and expensive as to make it economically impracticable. However, the presence of water in the alcohol in the first instance is not a drawback, as it has been possible to greatly increase the quantity of water and still obtain excellent results. In fact, tests have shown that the greatest amount of power is obtainable from a mixture consisting of 19 per cent. water and only 81 per cent. alcohol, its density being ascertained with a hydrometer.

Description of the Testing Apparatus.

For experimental purposes a single-cylinder, 3 1-2-horsepower, water-cooled De Dion motor has been employed, direct connected to a multi-polar direct-current generator, the fields of which are supported on ball bearings, so that the drag on the latter may be measured. The power developed is dissipated through a resistance consisting of a bank of lamps placed in a closet so as not to interfere with the use of the manograph. The mixture of alcohol and water is fed by gravity to a carbureter of the regulation float feed type and the alcohol spray

produced by the latter is led to a comparatively large chamber placed close to the cylinder. In this chamber a small amount of calcium carbide is placed on a wire screen so as to be directly in the path of the incoming alcohol spray. The suction of the motor draws the latter through this carbureting chamber and the water contained in the alcohol generates a corresponding amount of acetylene gas. In order to prevent any dust from the carbide being drawn into the combustion chamber of the cylinder a screen is interposed in the intake pipe.

While a carbureter has been employed in these early experiments, it is anticipated that its use will be found superfluous; as equally good, if not better results, will doubtless be obtained by spraying the alcohol directly on the carbide, after the Deutz or similar systems. The same is true of the carbureting chamber itself, which has been made unnecessarily large owing to the crude state of development of the apparatus itself. Experience has shown that the consumption of carbide is very small, and it is thought that a method of feeding it, patterned along lines somewhat similar to that used in the shaking grate type of generator, will be found satisfactory; that is, employing two inclined perforated plates or screens between which the carbide will be held. These and other mechanical details, such as the best size of the chamber, method of spraying the alcohol and the like, are matters that have to be worked out.

Theory of Alkoethine.

As has already been mentioned, alcohol burns very slowly, something like 1-20 of its total latent heat being required to burn it. This refers to absolute alcohol, and as the proportion of water increases, this factor grows correspondingly, which accounts for the fact that it has been found necessary to use a compression of 100 pounds or more with an r. p. m. rate of less than 500, together with a much longer stroke in order to build an efficient motor for use with alcohol as a fuel. This is taken advantage of by varying the proportion of water used, which in turn has a corresponding effect on the volume of acetylene generated. The resulting compound has been christened "alkoethine" by the inventors, and it is their theory that the mixture of air, alcohol vapor and acetylene gas is practically intermolecular, the heat generated by the conversion of the carbide into gas assisting materially in the vaporization of the alcohol. The theory of the action taking place in the cylin-

CARBURETING CHAMBER AND CONNECTIONS.

der when this fuel is employed is that the occurrence of the spark at the plug causes an instantaneous rise in pressure in the strata immediately surrounding it, and the molecules of acetylene gas throughout the mass are immediately detonated, serving to ignite the alcohol content without loss of time, so that the maximum thermic value of the fuel is obtained, com-

TRACING OF MANOGRAPH CARD; GASOLINE AT 1,300 R. P. M.

Combustion taking place at minimum volume or highest point of compression, as is shown by the fact there is less necessity of advancing the point of ignition in order to obtain the maximum power, than is the case with gasoline. Combustion is not in progressive strata, as is thought to be the case with the latter, but more in the nature of a true explosion. The carburetion process is entirely independent of the r. p. m. rate of the motor, as it is purely a chemical action, the mixture formed being much more homogeneous and thorough than could possibly be obtained by any mechanical means.

That a thermal efficiency, equivalent, or even superior, to that of gasoline is obtainable in a motor of the standard current design, may be seen from the fact that acetylene gas contains 21,492 B. T. U. per pound and gasoline vapor 21,900 B. T. U., while the thermal value of absolute alcohol is 28,500 B. T. U., the latter decreasing according to the extent of its hydration. But as this is practically disposed of when the alcohol spray comes in contact with the carbide, the latter robbing it of by far the greater part of the water, there is every reason to believe that the resulting mixture is a vapor having a value in B. T. U. somewhere between that of acetylene as above given and absolute alcohol, and consequently in excess of that of gasoline. The use of this mixture has also been found to overcome the

TRACING OF MANOGRAPH CARD; ALKOETHINE AT 1,400 R. P. M.

production of acetic acid, which invariably accompanies the use of alcohol alone, giving rise to corrosion of the cylinder walls and more or less pitting of the valves.

Some Experimental Results Obtained.

As yet investigations have not proceeded to any length, but experiments already carried out demonstrate that an efficiency

equal, if not superior, to that of gasoline is readily obtainable. No quantitative tests have as yet been made, but from the data obtained it is thought that the consumption of carbide will amount to about one pound per gallon of alcohol. Various proportions of alcohol and water have been tried, ranging from ten to twenty-five per cent., but at the latter point the explosions are of too violent a character, due to the large acetylene content of the mixture. A mixture containing seventeen to twenty per cent. of water has been found most advantageous, cards shown by the manograph when running on a nineteen per cent. mixture giving an initial pressure of 240 pounds to the square inch and producing almost ideal pressure and expansion lines, the compression of the motor being 65 pounds to the square inch. A large number of tests of this kind have been made and in the majority the range of mixtures referred to, i.e., alcohol containing seventeen to twenty per cent. of water, have been found to produce practically a characteristic gasoline card in the manograph, and, in some instances, a much straighter pressure line, indicating the greater rapidity of the combustion due to the presence of the acetylene gas. This is strikingly shown by the accompanying tracings of the manograph indication; in taking the latter no attempt was made at accuracy, as it is merely a pencil tracing from the ground glass of the instrument, and it is only reproduced here to give an idea of the character of the curve obtained. Both cards were taken from the same motor under similar conditions, one while using gasoline and the other with alkoethine, so that a comparison may readily be made, the latter card showing a much higher pressure line with an equally good expansion curve. It was also found possible to speed the motor to 2,100 r. p. m. under load, though its normal rate was 1,750.

That this system holds forth great promise commercially as a means of bringing alcohol on an economic plane with gasoline is quite evident. Present legislation on the subject, as altered by the recent amendments, makes it possible that denatured alcohol will be produced in the near future at a price very close to that at which gasoline is now marketed. Even in small quantities carbide now sells at three or four cents a pound and the cost of the latter is more than offset by the increase in the volume of the alcohol used by reason of the added percentage of water required.

AUTOS SUCCESSFUL IN POSTAL SERVICE.

WASHINGTON, D. C., March 11.—Representative Overstreet delivered a speech in the House of Representatives on the bill making appropriations for the postal service, in the course of which he called attention to the fact that for the last several months the Post-Office Department has been experimenting with reference to the rent of automobiles in the collection of mail and also in the distribution, which results in great expedition of the service. He stated that testimony was given before the Committee on the Post Office and Post Roads to the effect that while the charge for the individual automobile, including the driver, was considerable, yet the territory over which that vehicle could dispatch mail and from which it could collect it was so large that it covered from two to four collection districts where the mail was collected and distributed by the carrier with the aid of a horse and cart. He further explained that those individual mounted carriers who were displaced from the collection and delivery by horse and vehicle were then utilized in other parts of the territory and were not put out of the service. It was found, however, continued Mr. Overstreet, that great economy resulted from that change of practice.

"For example," he said, "I think in the city of Baltimore the experiment was very satisfactory, not only on account of the topography of the city, of the hills up which the wagons were obliged to be hauled, resulting in retarding the delivery of the mails, but, taking into consideration the number of mounted carriers to one district covered by an automobile, it resulted in a very material reduction of total expense."

MEN WILL AUTO FOR HEALTHFUL RECREATION

By CHARLES JEROME EDWARDS, TREASURER LONG ISLAND AUTOMOBILE CLUB.

THE future of the automobile industry will, I believe, be shaped, not so much by the man of wealth who inclines toward extravagance, but, instead, by the man of moderate income and modest pretensions, who will take up automobiling solely for its recreation and healthful features. In other words, the conditions of the future must be shaped somewhat by the demand of the enlarged clientele. My own belief is that we are at the parting of the ways; that we have reached the time where there will be two classes of cars—the very high-priced car, such as are represented by the foreign makers, for instance, and the medium-priced car, averaging, say, from \$1,500 to \$2,500. And to my mind the success of the automobile industry purely as a commercial proposition rests upon the ability of the manufacturers to provide for the general public this latter vehicle.

The good times and exceptional prosperity which all peoples have enjoyed during the last few years are surely to be followed by some one or two years of "hard times" at no very remote day, possibly three, possibly five years from now. This will hit the high-priced car very hard, and those of us who are enthusiastic and love automobiling, who may suffer thereby, will perforce have to be content with a less expensive creation.

The great field of the automobile in the future is to be among those who are new buyers, recruits to the army of amateurs who really have made the automobile industry. I think it will be agreed that, commercially speaking, the automobile has so far filled no great sphere, although of course a revolution will cer-

tainly be worked along those lines—but that, as I understand it, is not a subject under discussion. The future recruit to automobiling will very largely be the man whose income limits him to the low-priced car, and we find that sentiment extended all over the country. This is exemplified by the fact that the enormous number of second-hand cars which are disposed of each year go into country districts, and are in a sense an advance agent to reach the enthusiastic buyer of the future.

The era of good roads into which we are just entering will make every farmer of means, and the storekeeper and man of affairs in the various villages throughout the country, a convert to the use of the automobile, and his wants and opportunities are met by the low-priced car.

The recent show at the Garden was full evidence that the automobile manufacturers have in mind the production of this class of car—a moderately high-powered and reliable motor, which does not require an expert or non-expert chauffeur in order to handle it, but which can be understood and repaired by a man of average ingenuity and judgment.

This view of the situation is largely warranted by the fact that it was the single-cylinder machine which attracted buyers, and probably nine men out of ten who own high-priced cars began with the low-powered, inexpensive car. My theory is that the future will see nine men out of ten who become automobilists will do so because they can secure a good, reliable car at a comparatively small cost.

THE ENORMOUS DEMAND WILL CONTINUE.

By E. R. THOMAS,

PRESIDENT E. R. THOMAS MOTOR COMPANY, BUFFALO, AND E. R. THOMAS DETROIT COMPANY, DETROIT.

The enormous demand for automobiles experienced during the last year will continue throughout 1907. This demand enabled every manufacturer of a popular make of car to dispose of his entire output to dealers months ago. For the high class cars, the supply is entirely inadequate, and customers are already offering premiums to those who ordered early for their turn in delivery.

Our own condition right now is a truthful illustration of that with that of the leading manufacturers. We have orders on our books for cars amounting to \$5,500,000—over 1,500 automobiles—and with each one there is a deposit made to bind the contract. This is more than double the amount of business done last year.

As with every business, there are those who say every year that the demand is now at its height, and that it cannot last much longer. There is no truth in this, according to my lights. The demand that we have with us now will continue; the field is spreading all the time, and instead of the automobile industry being in danger of a slump within the next few years, it is my honest opinion that it is growing every day, and that the established manufacturers will be on an even solidier foundation and be doing a greater amount of business a decade from now.

WASHINGTON STATE IS BUYING MANY AUTOS.

SEATTLE, WASH., March 2.—Automobiles in great numbers for Seattle people have been tied up at various points along the roads westward, owing to the recent snow storms. They are now commencing to dribble through, and the agencies here are happy. Business here has been phenomenal thus far in the year. No less than 470 cars have been disposed of by Seattle agencies, a fairly good proportion of which are for various Puget Sound points. The aggregate value of the cars is \$600,000. This by no means represents the entire business to the Sound, as there are agencies in the different cities that are independent of the business here. The business in Tacoma is proportionate.

PRESENT LAWS SHOULD BE ABOLISHED.

By DAVE H. MORRIS,

EX-PRESIDENT AUTOMOBILE CLUB OF AMERICA.

A brief summing up of the present and future of the automobile, considered from its legal standpoint, makes legislation desirable that will result in the betterment of present conditions. The present law should be entirely abolished, and a new one substituted, of which the main provisions should be:

- (a) Driving to the common danger not allowed.
- (b) Elimination of all "miles per hour" prohibitions.
- (c) Penalties beginning with fines for first offenses, ending with suspended and revoked licenses, together with imprisonment.
- (d) Severe penalties for infraction of the law involving moral turpitude, such as receiving or demanding commissions, taking automobile without owner's consent, etc.
- (e) Annual license tax, the proceeds of which should be devoted to maintaining the new State roads.
- (f) Immediate review of any fine or penalty, by a superior act.

INDIANA FARMERS BUYING AUTOS.

FROM THE INDIANA FARMER, INDIANAPOLIS.

Editor "Indiana Farmer":

I am a reader of the "Farmer" and hear a great deal about the auto. I am a farmer and have ordered an auto; will have it by the first of March. Too many farmers always see the dark side of new improvements; some of them would howl if they were in heaven and St. Peter would give them a crown; they would ask for a better one. I think the auto has come to stay. I will admit there are some reckless auto drivers, but that is no reason you should condemn the machine. The law is in your favor; why don't you get after them? I know of several farmers in our neighborhood that expect to own autos in the near future. S. W.

This is as we predicted two or three years ago. Our well-to-do, ambitious farmers will own autos when the prices come down to hard pan; so it is well to be careful as to the laws we demand on the subject. Let them be just and reasonable; but farmers who are not able to buy, or do not care to own, autos have a right to demand that every precaution possible be made to protect their families from injury by them.

SOME PRACTICAL TYPES OF GARAGES

By GEORGE RICE.

ALTHOUGH the modern private garage is quite an expensive institution, I notice that a great many of them are being built. The custom of keeping the automobile in a shed, or an apartment of an isolated barn, or under some leaky roof of an outbuilding is fast being done away with. Automobiles cost too much, and too much depends upon the proper care of the same, to resort to poor building protection. Formerly the

FIG. 1.—Stable front altered for transformation into a garage.

automobile was purchased and then means sought to store and protect it. I have seen cases in which automobiles have been put out of service very early in the game, due to exposure in defective buildings. Sometimes the machine is exposed to dampness; and the rusting and corroding of the metal parts be-

gins almost immediately. I have seen the ignition system of high grade machines rendered non-effective after a week's exposure in a defective barn. Not infrequently no protection at all is obtainable, and the purchaser of the machine simply covers the same with a canvas. Then I have seen cases in which machines have been run into livery stables for temporary storage for want of better service. In fact, all kinds of ways have been utilized by machine owners for the care of their automobiles when not in use, some of which have proven to be quite disastrous to the car.

In this article we will refer to some of the modern types of edifices which are being designed for automobiles. It is by far the better way to first secure the storage. But, as before intimated, it is the custom for most enthusiasts to get the machine first and take chances on the rest. Perhaps the buyer owns a carriage shed or a stable, and he can put his newly purchased automobile in the same. But he finds that there are many facilities lacking.

The care of the modern automobile calls for equipments that are not needed in the care of common vehicles. Hence to utilize a building intended for other purposes is not always advantageous. Nevertheless, I have seen a number of stables altered over so as to make first-class garages, one of which is exhibited in Fig. 1. Much depends upon the character of the building. If there is an abundance of horse stall space, you can use these for other purposes and the stalls can come out. The harness room makes a first-class apartment in which to keep extra tires and various parts of the automobile, such as the extras of the mechanism, robes, rubber covers, etc. The first work involves the overhauling of the entire interior. You knock down your stalls and partitions which are liable to interfere with the arrangement of the automobile.

The two plans, Figs. 1 and 2, will demonstrate the arrangement. In this case, the windows and doors of the building were removed and the plain lights changed for the artistic description of sash with colored lights. This was done in the doors as

FIG. 2.—Floor plan arrangement for the autos and their appurtenances.

well as in the window sash. The exterior was painted an appropriate color, and quite a neat effect resulted.

The floor plan shows the arrangement of the automobiles. In order to give a place where the chauffeur can get below the machine and attend to any requirements there, a vat is made in the floor and the machine is run over this pit when an examination is necessary. The mechanic can get in the pit below with the electrical flash light or a common lantern and readily see the lower portion of the car. The floor is cemented. It is slightly elevated in which the machine is washed with a hose and nozzle, and the edges are grooved so as to carry off the water. There is a workshop over in one corner of the place, and no garage should be without one. There should be a vise, a work bench, taps and thread-cutting dies, drills, wrenches and the usual supply of tools and devices for doing work on the cars when necessary. It is a good plan to carry a small assortment of bolts, nuts, set screws, washers, lag screws, etc. You will, of course, have your kit of tire lacing devices.

FIG. 3.—Front of brick and stone garage.

The stairs at the rear of the store room lead to the rooms of the chauffeur above. Here you put in some furniture and make your man comfortable, and he will be more likely to look out for the machine well. He ought to have his bath, toilet, and other modern conveniences. As a rule the chauffeur will do most of the work about the machine and keep his apartments in order. I notice that some of the rich people have a helper for the chauffeur. He is usually a lad at low wages. Some people who run one or more machines go even further and have a mechanical man. But this is going rather deep into the game. A good chauffeur can attend to most of it. He may have to discard his brass-buttoned suit and get into overalls occasionally to wash the car, but this will not hurt him any. Of course, some people prefer brick or stone buildings for keeping their automobiles. Fig. 3 is a type of brick and stone building which impressed the writer. Buildings of this nature are preferable for districts in which a fireproof structure is needed. The middle door is for the entrance of the machines, and there is room enough on either side of the interior for a large car. The building is deep enough to warrant partitioning off for shop, extra part room, etc. There are the upper rooms for the chauffeur and general purposes.

A building of lighter construction, and cheap, is shown in Fig. 4. It is not desirable to have a building too much like a barn. Still, the plain edifice answers all purposes. Of the buildings referred, the values of each vary considerably. The brick building is, of course, the most costly. It would cost nearly \$3,000 to get a structure made of this nature, while an investment of \$400 will give you a building like that in Fig. 4. For about \$1,000 you can put up a first rate building of the

FIG. 4.—Small garage costing about \$400.

plan presented in Figs. 1 and 2. The best way is to get builders to figure on the structure. You can present sketches of what you desire and specify the details if desired. The contractors will do the rest, and save a lot of trouble for you.

Regardless of this, I know of a number of noted automobilists who have planned and erected the garage themselves. They made the drawings, selected the land, engaged the masons to put in the foundation, purchased the lumber and furnishings and watched every detail of the erection of the building from the basement up. Some men delight in doing this. But the average automobile enthusiast finds it better to turn the whole thing over to the experienced contractor, and let him do the planning and the thinking, at so much for the building complete.

AUTOS BECOMING NUMEROUS IN EGYPT.

U. S. Consul-General L. M. Iddings, of Cairo, transmits the following report on automobiles in Egypt:

The number of automobiles in Egypt this winter has greatly increased over those of last year. Machines registered in Cairo now number 264; last season, 75; in Alexandria, 127, as compared with 120 last season. In Cairo one or two new garages have been built. Most of the cars owned by residents are French,

but the tourists have brought in all kinds. The opinion of everybody is in favor of cheap cars, which have a closed-in top and are of small horsepower. There are no hills to climb. Roads for police service in the Eastern Desert are in construction by the mining department of the ministry of finance.

The road from Edfou to Beza has been completed, and consists of an excellent track 90 miles long. From Beza it will branch to the south and north. The southern line will go through the emerald fields, while the northern branch will join the Keneh-Cosseir road from the Nile Valley to the Red Sea. Keneh is another base for a road northward. This road is now building along the old Roman way, which was constructed in order to bring the property from the Red Sea coast to the Nile, where it was floated down the river to be sent to Rome. This road, as at present planned, is to end at Ghattar, which is 90 miles from Keneh, and is half-way to Gebel Zeit.

The Edfou-Beza road has been largely used for motoring, and the new type of motors, which have been built for the use of the department of mines, has been found satisfactory. Motors are a far less costly and difficult means of conveyance than camels. The longest day's run in the Eastern Desert was made last mid-summer, when 148 miles were traversed. During the last trip of the mining department's tricar 243 miles were accomplished.

FRENCH RENARD SIX-WHEEL AUTO TRAIN DEMONSTRATING ON ALDERSHOT PLAIN BEFORE BRITISH ARMY OFFICERS.

WAR OFFICERS INTERESTED IN AUTO TRAIN

LONDON, March 2.—The British War Office is at present paying much attention to the improvement of its transport service and experimenting with various kinds of tractors for cross-country work. Particular attention has recently been paid to the Renard train, the invention of the late Colonel Renard, a noted French engineer. The idea is not by any means new, for Renard died near Paris nearly two years ago, and at that time his train was a familiar sight on the highways in the neighborhood of the French capital. It is the first time, however, that it has been seen in this country, and its appearance has caused considerable interest among army officials and public transport companies. Briefly, the train consists of a tractor and a series of six-wheel coaches, each one of which has a pair of driving wheels and two pairs of steering wheels. In France various tractors were used for drawing the train, among them being a Serpollet steamer, a Darracq engine and a Panhard. For the British experiments a 75-horsepower Filtz four-cylinder gasoline automobile was employed. Power is transmitted from the motor at the head of the train to a countershaft on the car immediately behind it, the drive being through side chains to the center pair of wheels. The propeller shaft is extended to the rear of the car and connected by means of a universal joint to the shaft of the following car, continued thus throughout the

entire length of the train. For steering the front and rear wheels, turn at equal angles but in opposite directions, and in precisely the same degree as the wheels of the motor car and other trailers ahead. In the trials the train was made to make some very erratic turns, and in every case was entirely satisfactory, the rear wheels of the last wagon traveling to within an inch or two in the same track as the motor. With a train of four long coaches, altogether 73 feet in length, a circle of 29 feet diameter was described. Afterwards the same performance was gone through in a reverse direction, a man simply guiding the rear wheels of the last coach. Further experiments were made at Aldershot before a number of English military experts, the train being especially tested in its ability to accomplish cross-country runs. These tests showed that the train would be of considerable value in carrying ammunition and stores to the fighting line. Sixteen Renard trains are now in use in different parts of the world; their manufacture will shortly be undertaken in England by the Daimler Motor Company, Ltd. It is expected that they will prove of considerable service as feeders for existing railroad lines, carrying market produce and passengers from outlying districts to centers of distribution. The somewhat arbitrary auto laws of this country offer no objections to the circulation of these trains.

CUTTING WOOD INTO BLOCKS FOR SPOKES.

ROUGH SHAPING THE BLOCKS TO BECOME SPOKES.

MAKING WHEELS FOR AUTOS.

There is nothing of a complicated nature in an automobile road wheel; it has a metal hub in which are assembled wooden spokes, maintained at their extremity by a wooden band, encircled by a metal rim with special flanges for holding the pneumatic tire in position. Simple as is the product, the construction of an automobile wheel is a matter requiring highly skilled labor, the finest materials, special machinery, and the co-operation of a number of specialists. The illustrations on this and the following page show the upgrowth of an automobile wheel from the time the wood enters the factory to the moment when it leaves the works to be operated on by the painter and the tire expert. Whether it be the slender wheel of the ubiquitous runabout, a ponderous truck wheel with its iron band, or the touring car wheel, to be equipped with costly pneumatics, the process of construction is practically the same.

Suitable blocks of well seasoned wood are cut up to the length of the spokes by means of a band saw. Each block of wood has its end shaped by a special machine, forming a miter and tenon to suit the style of hub in which they will later be assembled. A moulding machine next plays an important part in the growth of the wheel. One by one the blocks are placed in the machine, the workman operates his lever, the circular plane comes into operation, and a few seconds later the block has assumed the familiar shape of a spoke. Up to this point there has been very little hand labor, yet it is necessary for the workman to have a vigilant eye and throw out any spoke which shows the least defect.

Passing to another workshop the finished spokes are assembled in a metal hub. The style of hub and methods of assembling differ considerably in the various factories. In the illustration herewith, which shows a heavy wheel intended for an omnibus, the spokes have been driven home by means of a mallet. The felloe has now to be fixed in position, and for this operation the spokes and hub are moved on to another workshop where a specialist takes them in hand. The felloe consists of two half circles previously bent into shape by a steam process. When the two halves have been placed over the ends of the spokes, secured and adjusted, the wheel is formed. As, however, it is impossible to allow the bare wooden rim to come in contact with the road, it is passed on to another department, where an iron band is made to encircle the wooden rim, giving additional strength, providing a running surface if the wheel is of the solid tire type, and an appliance for holding the pneumatic in position if it is of the rubber shod variety. This last operation is not the simplest of the many processes through which the wheel passes before it is fit to carry a flyer at a fifty-mile clip. The workmen engaged in this operation must be trained to work together, and must give full attention to the old adage "strike while the iron is hot." The metal rim is brought to a red heat in a special furnace, seized by three workmen armed with long gripping tools, and rapidly placed over the wooden wheel and driven into position with a few vigorous blows. For this operation the wheel has been placed in a kind of cast iron vat, plainly shown in the illustration. Immediately the rim is placed a few buckets of water are thrown over the wheel, the metal band contracts as it cools, binding all more tightly together.

FINISHED SPOKE LEAVING AN AMERICAN MACHINE.

ASSEMBLING THE SPOKES IN THE HUB.

PLACING WOOD RIM IN POSITION ON SPOKES.

The method of manufacture just described in that employed in one of the largest French wheel factories, the firm of Vinet & Boulogne, at Neuilly near Paris. The photographs were also taken in these works. This factory is one which first produced the dismantable rims which made such a revolution in last year's auto racing. Some of the rims will be noted in the engravings. In connection with wheel construction it is interesting to note that a large number of American machine tools are employed. The sturdy sabot-shod Frenchman shown operating at the foot of the preceding page has a lathe from the Defiance Machine Works, Defiance, O. In all the larger French wheel factories American tools are extensively employed, the products of such firms as Buckeye Wheel Company, Galion, O., House's Cold Tire Setter Company, St. Louis, being as familiar as the national article.

Such, in general language, and with an avoidance of technicalities, is the process by which an automobile wheel is built up. There naturally remain a number of finishing processes, but the wheel is practically complete as a wheel when the metal rim has been fixed. When it is remembered to what strains the wheels of an automobile are subjected from rough roads, lateral blows, skidding, and hard knocks against foot paths and banks, the necessity of the best of material and the most skilled workmanship will be apparent to all.

The proposal to erect a monument to the late Léon Serpollet on one of the public squares of Paris has met with hearty support in French automobile circles. Although only opened a few days ago, the subscription list has already reached the sum of 21,312 francs 20c.—about \$4,262.

DRIVING METAL RIM ON OMNIBUS WHEEL.

TWELVE HUNDRED DARRACQ CABS READY.

PARIS, March 4.—The first of the big series of motor cabs which several French manufacturers are constructing is now approaching completion at the new Darracq factory, near Paris. The Darracq machines, 1,200 in number, will be placed on the streets of different world's capitals, 500 going to London, 300 to Paris, 150 to Berlin, 100 to Vienna and 100 to Bombay. Two models are being constructed, one a two-cylinder 12-horsepower, the other a four-cylinder 18-horsepower. Characteristics are pressed steel frame narrowed in front, cylinders cast in pairs, 90 by 120 bore and stroke, mechanical valves, high-tension magneto, spray carburetor with automatic air inlet, high-tension magneto, tank and radiator combined, with high speed fan and thermo-syphon water circulation. There are three speeds forward and reverse operated by one lever under steering wheel, leather-faced cone clutch, internal expanding brakes, equal wheels 810 by 90, shaft drive, pan under frame. The weight of the two-cylinder model is about 2,090 pounds. The four-cylinder model may have either thermo-syphon or pump circulation, will have larger wheels, a longer wheelbase, and will weigh about 2,200 pounds. All the Darracq cab models will be fitted with landaulet bodies built by Vedrine, of Paris, and will be shipped complete. The new factory only began work at the end of last year, but the first complete series is expected to be delivered by the end of May. The total output of automobile cabs from the Darracq factory alone will be 2,500 per annum. When it is remembered that other firms, among them Bayard-Clément, Renault, C. G. V., and Unic are prepared to do business on an almost equally gigantic scale, it is not an exaggeration to predict the abolition of the cab horse at an early date. The sudden growth of this branch of automobiling has taken French body builders by surprise, few of them being able to turn out their product to keep pace with the chassis. A temporary delay is likely to be experienced on this account. Some of the best French body makers, foremost among them being Vedrine, have realized the immense importance of this trade and have commenced the erection of large factories for the construction of automobile cab bodies in series. So far as can be gathered, no definite arrangements have yet been made for the placing of French automobile taximeter cabs in New York.

FRANCE HAS THREE UTILITY CONTESTS.

PARIS, March 4.—The Automobile Club of France has approved the scheme of the Marquis de Dion to organize a touring and speed contest this summer. The event will consist of a 1,000-mile touring competition for machines weighing 3,630 pounds, with four passengers on board, but without tires, spare parts, tools or gasoline. An average speed of 24.8 miles an hour must be maintained throughout the tour, with a gasoline allowance of either 3.9 or 4.4 gallons per 62.1 miles. It has not yet been decided which fuel allowance will be adopted; the committee are in favor of the larger, but several competitors think that the smaller allowance would be ample. Machines qualifying in the thousand-mile tour must compete in a 248-mile speed test over a fast course near Trouville. The tour, to be known as the Criterium de France, will be held from August 2 to 6; the race, entitled the Press Cup, will probably be held on August 7. Teams of three may be entered by any firm at a cost of \$500 per car up to May 1. After this date and up to July 1 the fee will be increased 50 per cent. for every period of six days.

The date of the French industrial vehicle competition and small touring car test has been fixed from May 20 to June 10, thus occupying 20 days. Five types of industrial vehicles are provided for, from light delivery vehicles carrying not more than half a ton, to heavy wagons taking a load of 1 ton. The small touring-car competition is intended to provide for doctors' automobiles. All machines must be run on alcohol of 50 per cent. grade. They must carry two passengers, travel at an average speed of not less than 9 nor more than 18 miles an hour, and have total weight proportionate to cylinder area.

LETTERS INTERESTING AND INSTRUCTIVE

Important Laws in Pneumatics and Hydraulics.

Editor THE AUTOMOBILE:

[630.]—Being a reader of your paper, I wish you would answer my questions in the columns of your next issue: (1) State three important laws of pneumatics and explain an application of each to automobile engineering. (2) State three important laws of hydraulics and explain an application of each to automobile engineering. (3) In what way do cam mechanisms permit of results otherwise unattainable by mechanical means?

Erle, Pa.

CHARLES SCHOLZ.

If it will be of any real help to you, we are glad to answer your questions, though we note that these questions are those used in the courses of a well-known correspondence school, of which we assume you are a student, for which reason we are not altogether able to see why you should ask us instead of the school for the desired information. Three important laws of pneumatics are involved in the heating of gases by compression, in the cooling of gases by expansion, and in the expanding of gases by heating. In automobile engines, when the charges are compressed, they are heated thereby, and when they expand from the heating effect of their combustion they cool, while at the same time developing the power. An important law of hydraulics is involved in the fact that liquids are practically incompressible, another is involved in the fact that connected bodies of liquids have surfaces normally standing at the same level, and a third is the law of capillary attraction. In any forced-feed lubricating system a given movement of the pump plunger positively injects a corresponding amount of lubricant to the bearing, which is an application of the first law. The second law finds an illustration in any float-feed carbureter, in which the height of the fuel within the atomizing nozzle bears a fixed relation to the height of that within the float chamber. The third law also is illustrated by the float-feed carbureter, in that it causes the fuel in the atomizing nozzle to stand rather higher than it would if governed solely by the second of the laws enumerated. The way in which cam mechanisms permit results otherwise unobtainable by mechanical means is that they afford a variety of possible forms of movement which is practically infinite, which is not to be said of any other single device.

A Peculiar Trouble.

Editor THE AUTOMOBILE:

[631].—I have read with interest the letter in one of your recent issues from Jas. J. Thomas, Jr., since I have experienced something like the same trouble with the lubrication of my six-cylinder Ford car. The evidence of the trouble is that, with proper adjustment of the oil feed, the spark plugs of the first three cylinders must be cleaned very often, the fourth less, the fifth still less, and the sixth practically never. The spark plugs of the last cylinder are always dry and clean, in fact, but I have never had any trouble with overheating, scoring of cylinders, or seizing of pistons. I am sure that the oil is of the proper quality. There are no hills in this section of the country, the roads being perfectly level. The level of the oil in the crankcase was determined after careful experimenting with it at different levels. Any information you can give me will be greatly appreciated.

Norfolk, Va.

WM. S. ROYSTER.

It seems to us that the best way of securing satisfactory advice in a difficulty like the foregoing is to communicate directly with the manufacturer of the car. Are you sure, for instance, that you are using an oil approved by the Ford people? Of course, it seems rather singular that the fouling of plugs should progressively increase from the rear to the front cylinders, though this in itself is hardly a serious matter, inasmuch as any spark plugs are fairly certain to become fouled occasionally, under certain conditions. Possibly the manner in which lubrication is effected has something to do with the difference. Usually fouled plugs may be taken as an indication of over-lubrication, though adjusting the oiling should correct this if it exists.

V. L.

Electric Lamps for Automobile Lighting.

Editor THE AUTOMOBILE:

[632.]—There are a number of things I would like to know about electric lights for automobiles, and I trust you can furnish me with the desired information. First, it appears to me that the storage battery is the most satisfactory source of current, since a dynamo is difficult to regulate, and, besides, cannot furnish power when the engine is not running. Second, in view of these conditions, it is desirable that the greatest light with the lowest current consumption be secured, making it an object to utilize something more efficient than the ordinary incandescent lamp. And, third, if the objects stated could be realized, electric lighting would be much more satisfactory and efficient than the acetylene systems now in vogue. What is the reason that the Nernst lamp, or the new tantalum, tungsten, and osmium lamps cannot be used, with the result of securing much better efficiency of illumination than so far has been found possible?

Topeka, Kan.

CHESTER K. SCOTT.

It is altogether possible that the future may bring some improvement along the lines you suggest, but at the present time there is little to indicate that success awaits their first trial. The Nernst lamp, in its present most successful forms, requires current at a voltage too high to be supplied without more storage cells than would be regarded as convenient on the ordinary gasoline car. And the filament of the Nernst lamp is of a mechanical strength scarcely sufficient to withstand the jolting to which it would be subjected on a car. The other new lamps you mention—those of the incandescent type, with filaments of certain of the rare metals—are scarcely tested to the point of thorough success, even in general applications to commercial lighting, so their possible value in automobile service is altogether an unknown quantity. The tantalum lamps, especially, probably suffer injury from jarring.

The Combustion of Compressed Mixtures.

Editor THE AUTOMOBILE:

[633.]—Can you refer me to some book or article on the subject of automobile engineering from which I can secure data concerning the action of mixtures fired under pressure? What I particularly desire to learn is the rate of flame propagation and the amount of pressure rise in different mixtures ignited at different pressures.

Portland, Ore.

ALFRED ROGERS.

What we must confess as an absolute inability to give a satisfactory answer to your questions constitutes one of the many startling evidences that exist to prove the developing status of gas engineering. So far as we know, if any tests of the sort you specify ever have been made, the data secured from them has not been made public. A number of years ago, Dugald Clerk, the well-known English engineer, made some rather elaborate tests with gas mixtures at atmospheric pressure, while at the Massachusetts Institute of Technology some similar tests were made. From the meager facts thus made available all of the stock theories of desirable mixture proportions are derived, despite the fact that very little is known concerning the action of mixtures under pressure. If any one who reads this can give more information on this interesting subject, the columns of THE AUTOMOBILE are open to it.

More About Fording Deep Streams.

Editor THE AUTOMOBILE:

[634.]—Taking up question No. 606, would like to ask why he could not ford streams if he should have intake pipes made to his carburetor so they would rise above or even with the commutator.

Providence, R. I.

W. W. GRANT.

Merely raising the intake piping above the water-level would not prevent water entering the carburetor and putting it out of commission, but the carburetor entire might be placed above the cylinders instead of down at the side as is ordinarily the case. However, the answer to the question

was based on the assumption that no changes of any kind were to be made in the car, as the query was not what could be done to the car to make fording deep streams possible, but rather how to ford them when the carbureter is under water. Placing the carbureter where it would not be submerged would, of course, constitute a remedy for the difficulty, but it might also involve changing the system of fuel feed, as where gravity is employed, or the installation of an auxiliary feed for use under such circumstances, with the engine hermetically sealed and outlets provided, it would run under water.

MORE ABOUT DAIMLER AND THE TWO-CYCLE.

Editor THE AUTOMOBILE:

[635.]—I notice in the issue of February 21 the comments of T. J. Fay, in reference to what I said about the Daimler gas engine, which remarks seem for some reason to have made him quite sore, so much so that he seems to have lost sight altogether of the question that gave cause for the statement.

What I said of the Daimler design was true, and if it was not, Mr. Fay is not doing anything to show that it is not. Generalities about Daimler's pioneer work prove nothing. If I remember right, Brayton used liquid fuel long before Daimler did, but being hampered for means, failed to make as much of a success as his originality and talents deserved, which was far from being the reason why Daimler did not make a greater success of his. I think that I am safe in assuming that if Brayton had had the backing that Daimler had, gas engines would have been developed to a higher stage of perfection long before they were. A man's achievements have to be judged largely by his opportunities.

I still maintain that Daimler's construction was not so perfect as to justify referring to it as a precedent, justifying any kind of a design, as though that settled the question that Daimler's construction was above criticism. As I understand it, the only point at issue is whether my criticism of two-cycle engines that admit the charge into the cylinder through a checkvalve in the piston head, the piston head being the valve seat, was warranted by the facts of the case, which I think was fully answered in the reply, from which Mr. Fay is quoting, and to which he so much objects.

It seems to me that it is much better to base arguments as to the efficiency, or inefficiency, of any construction upon the reasonableness of the thing, rather than on precedent of some "has been" construction. The theory and practice of gas engine construction is being constantly revised; for instance, no longer ago than when Daimler made his first gas engine the almost universal practice was to leave one-third of the cubic capacity of the cylinder for compression space; now everybody believes in high compression, and it would seem absurd for anyone to try to prove that low compression was the best because Daimler's engines were low compression; I think that it is equally absurd to try to prove the efficiency of any other construction by holding up Daimler as an argument.

I am very glad to know that Mr. Fay is going to build a two-cycle engine, and wish him every success, and from his remarks about Mr. Loughheed's opinions, I infer that he intends not to follow the beaten path, but bring out something original. If I am right in my surmises, he might read over some of my writings which were recently published in "The Automobile"; the ones that I refer to were published in the issues of December 27, 1906, the other January 3, of this year. If, however, he intends to build the up-to-date standard two-cycle type, he would do well to read the articles published in "The Automobile" in the earlier part of the fall of 1906.

Unless he has had a wide experience in designing two-cycle engines, it will be worth his while to read over all of these papers, and see just what progress has been made in bringing the two-cycle up to "be somebody." I am under the impression that he has not quite kept up to the advancement that the two-cycle has already made. For myself, I have unbounded faith that the two-cycle will soon be the gas engine for every purpose where the greatest power, with the least weight, least complication of parts, are matters of any importance, and although there are no two-cycle engines yet on the market that fulfill my ideal as to some of the requirements, yet to-day it will develop more power than a four-cycle, size for size, and by some manufacturers and users of automobiles is preferred to the four-cycle. Come to think of it, it was perfectly natural that the four-cycle should be perfected first, before there should be much progress in perfecting the other, for that is the natural order of evolution, from the more complicated type toward simplicity. We welcome Mr. Fay to the ranks of two-cycle designers, and will all wait with breathless interest while he solves the problem of the perfect two-cycle gas engine.

C. P. MALCOLM.

Detroit, Mich.

CAN ANYONE CLEAR UP THIS MYSTERY?

Editor THE AUTOMOBILE:

[636.]—The writer would like to have you or some of your numerous readers explain if possible through your "Letters Instructive and Interesting" the following phenomena.

When at the end of last season's use my car was put away for the winter the lamps and generator were removed, leaving the rubber gas tubing which attached the copper tubing to the lamps and generator hanging loose and the ends of same open. A short time ago, when overhauling the car, parts of the copper tubing were found slightly bent in places, and upon taking the copper tubing in my hands to straighten these bends was very much surprised to hear, as soon as the bending was started, a considerable explosion and see flames shoot out the ends of these tubes. The explosion was nearly as loud as a pistol discharge, and of sufficient force to tear loose the section of rubber dangling on the ends and blow same across the garage, a distance of twenty or thirty feet.

There was no fire or open light to ignite any gas that may have remained in this tube during these weeks of idleness, and as can be well imagined the writer was very considerably surprised. On bending the other copper tube leading to the other lamp the explosion was repeated in exactly the same manner, and it seems quite improbable that the slight bending of the tube could create enough frictional heat to ignite a gas that might have remained in these tubes.

This is a new experience for myself, and if anyone can and will throw some light upon the cause of such explosion, would gladly have them do so through your valuable publication.

Schenectady, N. Y.

B. A. BURTISS.

A COMBINATION COOLING SYSTEM MOTOR.

Editor THE AUTOMOBILE:

[637.]—Relative to letter No. 538 in February 21 issue of "The Automobile," by "A Subscriber," I would infer that the question has reference to a combination air and water cooling system, in

the nature of an interchangeable system, using either air or water without the changing of cylinders, it being understood that most of the motors in present use are on this order, as the heat must be extracted from the water by the air.

For your information, as well as for that of your subscriber, I would say that I have an engine, constructed upon the lines referred to, which has an increased cooling capacity for either air or water, with less weight to the cylinders in accomplishing the result; with a removable water jacket and an improved system of air flanges, all of which go to make an interchangeable cooling system. For your assistance on the subject, I submit herewith drawings of engine. If any other information regarding its

SHEPHERD'S COMBINATION SYSTEM.

advantages are desired, I will be pleased to furnish you with any details you wish; or should any of your readers wish to have the working of this system explained more at length, will do so.

Rutland, Ill.

C. G. SHEPHERD.

PRESS THE BUTTON AND LIGHT THE LAMPS.

Editor THE AUTOMOBILE:

[638.]—In your issue of February 21, under "Letters Interesting and Instructive," there is one, No. 583, signed W. L. K., relative to an appliance for lighting headlights by pressing a button. Would say that we have at the present time in operation a contrivance of this sort for lighting gas lamps which uses a jump spark and lights the lamps by pressing a button close to the seat of the car.

Amesbury, Mass.

GRAY & DAVIS.

ENTIRELY due in the first instance to the Touring Club de France, a great national road has been laid out in recent years along the edge of the Esterel range of mountains and the blue waters of the Mediterranean.

Not every Riviera tourist knows the wonderful region of the Esterel as well as he ought, and not every automobilist to the south of France passes by this new-laid-out "corniche"—the peer even of the more famous "corniche" between Nice and Monte Carlo—preferring to go by the old road, the Route d'Italie—to the north of Mont Vinaigre, the culminating peak of the Esterel, 2,000 feet in height and a dozen or more kilometers from the shore. This is all wrong. One should no more make the Riviera tour en automobile and miss this forty kilometers of the most superbly situated and ingeniously engineered roadway, perhaps, in all the world, than he should attempt to lunch en tour on a ham sandwich and a bottle of Vichy, as more than one scorching automobilist who was trying to tour Europe in ten days has done before now.

All Riviera tourists, and some others, know that the Esterel is a great curtain of reddish-brown porphyry rock which comes down to the Mediterranean just westward of Cannes and shelters that "ville d'aristocratic anglais," as the French call it, from the icy breath of the mistral of the Rhone valley. This much they know but not much else; they take their cue from what they remember of Lord Brougham's pilgrimage three-quarters of a century ago and think that there is nothing worth seeing on the Mediterranean coast west of Cannes, forgetting for the moment that the city of Fréjus spurned the offer of England's Chancellor to make it a winter rest-house for the noblesse of "brumeuse Angleterre." Perhaps the city fathers were wise to have rejected the proposition. Who knows?

Gateway to the New-Made Corniche.

At any rate, Fréjus is the gateway to the new-made "corniche" and is a dead, dull town with nothing at all of the life and conventional pleasures of the real Riviera. The Hotel du Midi at Fréjus is the last inn of its class to be found on the Riviera as one goes east. It is modest, frankly commercial, and you will have difficulty in spending more than nine francs a day for your food and lodging.

The Esterel range itself is to a great extent a vast dominial forest peopled largely by that species of evergreen pine known as the *pin maritime*. The forestry department of the Government

here steps in and has its say and tells you when you may and when you may not cut down trees, and where you may cut a path and where you may not, so that there has been considerable method in the laying out and opening up of this hitherto virgin fastness. Since 1891, only, have any but the inhabitants of the neighborhood ever explored this mountain wildwood which the French fondly compare to "le Yellowstone," but to-day there are 240 kilometers of forest roadway of which considerably more than half is practicable for automobile traffic.

That Radiator Repair Worth Remembering.

All the same there is a savagery about the interior of the Esterel which on occasion can offer something in the way of adventure, as for instance it once did in the writer's case. We were stalled in a grim, stony defile while the water had all trickled out of our radiator, or rather the hose-pipe connection had itself, in some way, mysteriously disappeared, *tout entière*. There was nothing for it but a twelve-kilometer walk over and back to the Auberge des Adrets to see what the Poste de Secours, thoughtfully established by the Touring Club de France for the benefit of distressed cyclists and automobilists, might offer. It didn't offer us anything that would do us any good, but this might have been expected. There was all sorts of little things which would help out with a refractory nut or bolt; there was copper and iron wire and a whole tire repair outfit; besides which there was a good workable pump and a first aid to the injured box of medicines. All very thoughtful and a blessing to anyone who might want these things—for which you pay nothing; though, unless you are a dead beat, you donate something to the "cantonnier" of the neighborhood who has the *boîte de secours* in his charge. We got a piece of hose-pipe finally from the garçon d'écuries at the auberge, and in spite of a three hours' delay took the road again none the worse off.

Four kilometers from Fréjus one passes through St. Raphael, unless, indeed, he wants to linger within the purlieus of this altogether delightful, unspoiled bit of the southland. In recent years it has grown to a population of 3,000 souls, and until one reaches La-Napoule there is no such metropolis as this on the whole "corniche."

Boulouris, Agay and Antéore are not even names recognized by most Riviera tourists, but one and all are delightful, little new-found spots which have not yet been exploited to the death, even though they have become possessors of a

OLD-WORLD STOPPING PLACE IN THE MIDI.

hotel-restaurant or pretentious establishments bearing the title of "Grand Hotel."

The Estérel Not for Sordid Automobilists.

If any automobilist is of the mind to rush through this wonderland "all out," he had best stick to the northern road and leave the corniche to the true vagabonds who like to linger where fancy wills. The sordid souls who have taken up automobiling merely for the sake of rushing through space will be quite as content with a circular track as with this twisting, turning road of the Estérel, even though there are some of us who think differently. One day, or two, or three, spent in the Estérel will be time well-spent and the pleasure and delight that will accrue will be immeasurable.

To reach the interior mountain roads one's best point of depart is from Agay; otherwise it is better to keep on to La Napoule and enter from the north.

Corsica Can Be Seen, 200 Kilometers Away.

More than 200 kilometers distant, bedded on the cloudy fringe of the horizon, one may sometimes see—not always—the angular heights of the Corsican isle. Northward the view is as entrancing; far beyond the foot-hills upon which rise Grasse, Castellane, Puget-Theniers, and their sister-towns of the Alpes-Maritimes and

PICTURESQUE MOUNTAIN ROAD.

the Var, may yet be seen the snows of the southernmost of the Alpine peaks proper, many of them of a height of more than three kilometers straight skyward, the queen of them all being "La Punta Aigentera," rising to a height of almost 5,297 meters.

From Trayas to Theoule is fourteen kilometers of daringly built roadway, now passing over a deep-cut bay or *calanque* and now freeing the railway by a sky-scraping viaduct and once and again sweeping a curve around some rocky promontory on a shelf cut sheer in the rock itself.

Only Six Francs a Day!

Things begin well with the Corniche d'Or the minute one launches his automobile on the road leading out from Fréjus, but before Agay has been reached one has warmed to it so that his appreciation of the latter half of the journey will know no words to do it justice. Right at the edge of tide-water one follows the western shore of the Golfe de la Napoule over which poets and painters have raved as they have over Capri and its grotto. Everything but nature itself is as yet in embryo and the disturbing influences of civilization have not yet become so great as to mitigate one's pleasure. At Theoule the Hotel de l'Estérel has arrived, but its pension prices have been until recently—and are still if the patron has not gone the way of most of his degenerate confrères on the Riviera—but six francs a day. Think of this! Ye who sport around at Atlantic city, Old Point, and Tampa Bay at prices anything you like to pay.

To avoid the five o'clock teas and "sportsmans" of La Napoule which comport so ill with the rare beauties of the Mediterranean littoral, it is well to keep the road a kilometer or so further and then turn abruptly to the left, leaving the coast behind. In a dozen kilometers or a little more, you will come to the Auberge des Adrets, a genuine unspoiled *logement* and not much more. To-morrow you can roll gently down into Cannes, "the ville of the Grand Ducs and the English aristocracy" and be as blasé as the rest of them, but stave it off for one more night anyway.

As Quiet as in the Days of Macaire.

There is nothing at the Auberge des Adrets to suggest modernity save the rushing by of an occasional automobile on the great "Route d'Italie" in the dead of night. For the rest it is as quiet and tranquil as it was in the days when Macaire and his fellows held up unsuspecting travelers by coach and chaise and relieved them of their all.

It is all very crude and rough here and you may get a bed for a franc and a *repas* of a primitive order for another franc—or more, if you choose to pay it. The wind sighing through the *chataigniers* will lull you to sleep and as you wake in the morning with the sun just tipping the summit of Mont Vinaigre you will be almost ready to give up automobiling and go back to the old days of the romantic *poste-chaise*. You won't seriously think of do-

BESIDE THE BLUE MEDITERRANEAN WATERS.
ON THE CORNICHE D'OR.

A VIEW OFF SHORE.

ing this, of course, for we have become spoiled in recent generations, but the thought will occur to you nevertheless.

All this tranquillity and romantic idealism is within a dozen kilometers of the nerve-destroying distractions of Cannes, Nice and Monte Carlo, or at least the gateway thereto; where you become a frequenter, whether or no, of the Cercle Privé, of tea-shops, of alleged American bars or of Monte Carlo's game and restaurants who serve "les mutton chops" and "pal' ale."

Touring Club Helped Build the Estérel Road.

The Estérel road was planned and built by the combined efforts and expense of the French nation, the Départements of the Alpes-Maritimes and the Var, the Touring Club de France, and the P. L. M. railway. This latter seems somewhat of an anomaly—a railway contributing to build a stretch of roadway which shall be in direct competition with its own powers and functions—but it is a fact, nevertheless. As an engineering triumph the road must rank as one of the great works of its class of any age—and they were mighty good road-builders in France even in the days of the Romans.

For almost its entire length the road runs beside the *chemin de fer*, crossing ravines and gullies often on the same shelf of levelled rock. For the most part it is something over ten meters in width, but in places it narrows down to half this. There are no rises or descents which exceed 5 per cent., and when these one in twenty grades occur they are not very long.

THE COMING MOTOR BOAT RACES AT MONACO

IN numerical value the great annual motor boat meeting to be held at Monaco April 1 to 16 surpasses all its immediate predecessors. When the entry list closed this week the International Sporting Club of Monaco, which organizes this meet, had enreregistered a total of 90 boats in all classes. As is always the case in these meetings, a certain proportion of the entrants will fail to put in an appearance at the starting line, but with this allowance the number will be sensibly above that of last year's meeting, which united sixty-six actual starters.

As in previous years, the Monaco programme will consist of an open-air exhibition in the picturesque ground of the Condamine, with the bold cliff as a background and the blue waters of the Mediterranean in front. It is an ideal spot for an early spring sojourn, and it is no matter for wonder that the fortunate and elegant idlers of the wide world congregate in the neighborhood at this time of the year. Monaco is important as a society meet, but it is surpassed as a sporting enterprise. Three distinct classes of boats are provided—cruisers, racers and sea-going vedettes. Cruisers are divided into four classes, with a limited length and proportionate cylinder capacity, beginning with 20-foot boats having 21-2 liters cylinder area and proceeding by stages to comfortable, roomy cruisers of 60 feet over all and a 15 liter motor. Only two classes are provided for the racers, up to 26 feet over all and above 26 feet in length. The sea-going vedettes are a new class now being given considerable attention, with a

view to their adoption in the fighting marine. The regulations stipulate that the length of these craft shall not be more than 25 feet, and total weight 2,640 pounds, all included except the motor and its piping. A number of these small rapid boats have been built for the French navy, to be used for vedette service in the home waters, but this is the first time that they have had a class provided for them in the Monaco meeting.

Monaco maintains its reputation for big prizes. The four classes of cruisers have \$5,800 in cash as their prize money, the two racing classes will compete for \$3,800, the vedettes have \$3,000 and the poorly represented hydroplane class can win \$600. In addition there are \$8,800 devoted to a number of handicap races for cruisers and racers, the championship of the sea, and the mile and kilometer records. Among the trophies are the Prince of Monaco's Cup and a magnificent work of art presented by M. Thomson, French Minister of Marine, for competition among the vedettes. With a grand total of \$22,000 in cash, it cannot be doubted that the competitors will win more than will cover their heavy expenses, while the advertising value of a series of victories will be worth no small amount. Unlike the big motor boat meetings in America, the Monaco tournament is a purely trade display. Even the cruisers are entered and run in most cases by either the hull maker or the engineer, or the two in

conjunction. The racers, though in a few cases piloted by wealthy sporting amateurs, are purely trade boats, as is indeed indicated by such titles as *Panhard-Tellier*, a Panhard motor in a Tellier hull; *Mercedes-Florio*, *Itala*, *Daimler*, *Antoinette*, etc. The same thing applies to the vedettes, the success of which in the races will doubtless largely influence their adoption by the naval authorities.

There has been a healthy development, but no radical changes in the cruisers. Earlier tendencies of the French to construct only light boats for river work are not now so pronounced, a number of the new boats being large, comfortable cabin craft, capable of facing a reasonable amount of rough weather. Two at least of the new cruisers use kerosene as fuel.

Racers are still the center of attraction, despite the prophesies that were issued of their speedy disappearance when early blunders brought upon them

the witticism of the world. Though slightly decreased in numbers, they are, however, of greater interest than ever before. The utter disproportion between hull and motor, river-going hulls for sea service, and inadequate protection for the motor against flying spray and an occasional wave breaking on board have been largely remedied in this year's craft. Hulls were more at fault than the motors, with the result that few of the more powerful craft could be let out to full power for fear of a collapse. In the first series of racers there are but half a dozen boats all close to their 26 foot limit and all of considerable interest. *La Ra-*

SPECIAL MERCEDES ENGINE IN FRENCH HULL FOR ITALIAN OWNER.

pière II., the successor of the famous but unfortunate *Rapière* with which Tellier defeated all comers, will be watched with considerable interest. Panhard-Levassor is responsible for the engine work and Tellier & Gerard are the builders of the hull. The Antoinette Company, famous for its lightweight motors for flying machines and motor boats, presents a 24-cylinder motor in a boat bearing the name *Antoinette V.* The Itala firm has a 135-horsepower motor in a 26-foot hull christened the *Itala*. Fiat has engaged a fast boat bearing their name to be driven by an 8-cylinder engine. The most remarkable boat of the meeting is the *Mercedes-Florio*, owned by the well-known Italian sportsman, the Chevalier Florio and engined by the Mercedes firm. The hull is entirely of steel, 26 feet 4 inches long, 97 inches wide, drawing 7 inches of water. G. Pitre, the boat builder of Maisons-Laffitte, near Paris, has designed the hull on entirely new lines. The bow is of the form of a horseshoe, the sides are perfectly straight and the stern is squared, the object being to reduce surface friction to a minimum. The hull is divided into four compartments; forward is a water-tight compartment, next the open engine pit, protected by high combings and provided with a movable, water-tight hatch; a small cockpit for the pilot, containing two gasoline tanks, with a special arrangement by which the gasoline can be rapidly

HENRY FOURNIER'S FAST CRUISER WITH ITALA ENGINE.

emptied into the sea in case of fire, and a large water-tight compartment astern. The craft is a marvelous piece of metal work, exceptional care having been taken in the rivetting of the thin plates to produce a light but very strong boat. The boat has two rudders. A special 6-cylinder 150-horsepower Mercedes motor supplies the motive power. Pitre expects to reach a speed of forty-five miles an hour with this original gliding boat.

The big racers over 26 feet in length comprise seven or eight entirely new boats and a small number of last year's racers. Brasier continues the *Trefle à Quatre* series with a *Trefle à Quatre II*, carrying a 4-cylinder 120-horsepower Brasier motor in a wooden hull. Henry Fournier will pilot a fast *Itala* boat of about the same horsepower; the Chevalier Florio will have an *Itala* motor in his big *Jeanette*; Panhard will engine the *Panhard-Tellier* and the *Paris*, the latter with a 135-horsepower Grand Prix type of motor, driving two propellers; Dietrich will have the *Lorraine-Dietrich*, equipped with a 130-horsepower motor of the type that was so successful in the Ardennes Circuit; *Mendelssohn IV* is another powerful lightweight motor bearing the name of the maker of its engines; the *San-Giorgio* will defend the fame of the Italian firm of that name. The English, who have always been greater rivals of the Latin races on water than on land, present a strong trio in the *Daimler II* and *Daimler III*, both owned by Lord Howard de Walden and engined by Daimler of Coventry, and a craft built by Saunders for Lionel de Rothschild to be engined by Wolseley.

STERN VIEW OF MERCEDES-FLORIO GLIDING BOAT.

Despite the encouragement that has been given them, hydroplanes will not be well represented. It is probable indeed that the only starter will be the *Nautilus-Obus*, built by Deschamps & Blondeau and engined by Mutel. This curious craft consists of two floats, each 6 1-2 feet long by 6 1-2 feet wide, united by an ash framework stiffened by metal stays. The frame is 23 feet long by 23 inches wide. The total length is 28 feet and the total weight 1,210 pounds. The frame is fixed to the two floats by two axles and springs like those used on an automobile. On the foremost float is placed the 4-cylinder 55-horsepower motor, and on the other the pilot's seat, the gasoline tank and a steering wheel and column, as in an automobile.

A NOVEL FLOOR PLANING MACHINE.

Although American automobile manufacturers have not yet obtained much hold on the French automobile market, various kindred and tributary industries are better represented in the home of the auto than is generally imagined. The accompanying illustration shows an American motor floor-planing machine at work on the Velodrome d'Hiver cycle track in Paris. The machine, which is being demonstrated in Europe for an American manufacturer by O. L. Pickard, automatically planes a floor and

AMERICAN OPERATOR AND MACHINE PLANING PARIS TRACKS.

gathers up its own shavings. The Velodrome d'Hiver on which the experiment is being made is a very popular winter indoor cycle and motor cycle racing track, forming a part of the huge machinery hall of previous international exhibitions. There are about half a dozen of these cycle tracks in the French capital, most of them open only in summer; the one in question is closed in summer and open in winter. By this arrangement interest in track racing is kept alive all the year round. A sight of the crowds leaving the "Vel d'Hiv" any Sunday afternoon is sufficient proof that the sport has lost none of its old charm for the French.

THE AUTOMOBILE AS A MONEY EARNER.

Early holders of stock in the now world-famed automobile firms are reaping a rich reward as the result of their foresight, sagacity or luck. To take but a few of the best known French automobile concerns, Panhard & Levassor shares issued at 10,000 francs were quoted at 65,000 francs at the beginning of this year. In a recent commercial deal their value was fixed at 105,000 francs, or more than ten times par value. Darracq shares issued at 25 francs are now worth 75 francs. Dietrich shares with a nominal value of 500 francs are now quoted at 1,100 francs. Rochet-Schneider has passed from 500 to 3,000 francs. Richard-Brasier, C. G. V. and Krieger shares have increased in market value 150 to 500 per cent. Such tire houses as Michelin, Hutchinson and Bergougnan pay annual dividends of from 10 to 25 per cent. Congo Colonial Societies, whose chief product is rubber, have been phenomenally successful.

MOSTLY ABOUT THE EASTERN CLUBS

Recent Activities of the Busy Cleveland Club.

CLEVELAND, March 11.—The Cleveland Automobile Club is working out two new schemes of benefit to its members and to automobilists in general. One of these is the publication of a register of the numbers and names of automobile owners in Cleveland and vicinity, as well as the make of the car. The names will be given in alphabetical order in one section, while in another the list will be arranged according to the license numbers. The records will be brought up to date at frequent intervals. Another innovation is a registration bureau for chauffeurs. A large number of chauffeurs have already registered with Secretary Asa Goddard, and he has found positions for a number of good men with owners who will have new cars in the spring. No charge is made at this intelligence office, either to the chauffeur or to the employer; furthermore, Secretary Goddard does not recommend a man until he has assurance that the applicant is a skillful and careful driver and is familiar with the handling of any make of car. Mr. Goddard is co-operating along with the Y. M. C. A. automobile school in this work.

The recent automobile show greatly benefited the Cleveland Club. The club had a special reception room at the show, and as a result of the missionary work done at that time more than fifty new members have been secured. This is but one of the many evidences of the wonderful increase in the number of those interested in the automobile in Cleveland.

Secretary Goddard delivered an address at the opening of the Y. M. C. A. school's spring term. He spoke of the development of the automobile industry and its future and the kind of training men need in order to enter the work as shop employees or drivers. Mr. Goddard expressed the opinion that twenty years hence horses will be an unknown quantity in the streets of large cities and that motor vehicles will wholly supersede them.

Fuel Test Not Included in New Jersey Endurance Run.

NEWARK, N. J., March 9.—Economy in fuel consumption will not figure in the endurance contest of the New Jersey Automobile and Motor Club to be held on May 30, 31 and June 1. Owing to the difficulty of arriving at a basis satisfactory to touring machines and runabouts of different horsepower, it was finally decided to drop the fuel test entirely. The action does not meet with the approval of all contestants; for, owing to the especially good nature of the roads over which the run will be held, it is feared that a number will tie for the trophy. Strict adherence to the speed laws and a prompt arrival at the controls will now be the feature of the tour. A driving schedule will be fixed, any car arriving at the controls ahead of time will be fined two points for each minute, while late arrivals will cost the delinquent one point per minute. The trophies will be the Shanley cup for touring cars and the Sinclair cup for runabouts.

A. C. of Buffalo Will Listen to Mr. Glidden.

BUFFALO, N. Y., March 11.—Secretary D. H. Lewis, of the Automobile Club of Buffalo, announces that Charles J. Glidden, donor of the Glidden trophy, will deliver a lecture to the members of the club, March 22. The affair will be known as "Ladies' night." Concert Hall has been engaged for the occasion. Mr. Glidden's subject will be, "The World as Seen from a Motor Car." The lecture will be illustrated with stereopticon views.

At the recent meeting of the club twenty-five new members were elected. The membership of the local automobile club is increasing with such rapidity that it will soon be one of the largest automobile clubs in the world. There is a strong probability of more members being added in the near future.

Capital City Autoists Get a Speed Limit Doubled.

WASHINGTON, D. C., March 11.—Automobilists of Washington are delighted with the action taken last week by the town council of Glen Echo, Md., in amending the ordinance regulating the speed of automobiles within the corporate limits of that town by increasing the speed limit from six to twelve miles an hour. This gratifying action was the result of a recent conference between R. B. Caverly, president of the Automobile Club of Washington, and the Washington Automobile Protective Association; C. M. Fulton and W. S. Duvall, attorneys for the association, and John Garrett, mayor of Glen Echo.

This conference was held in Washington, and during its course the representatives of the automobilists admitted their defeat in their efforts to prove that the town of Glen Echo and Montgomery county had no jurisdiction over the Conduit road in criminal cases. They suggested that the town ordinance be amended so as to conform with the State law, which fixes the speed limit at twelve miles an hour. They also agreed to drop all the pending litigation. This was agreeable to the Glen Echo authorities and the necessary amendment to the town ordinance was thereupon made.

Motor Scooter Club of America Formally Organized.

NEW YORK CITY, March 11.—An addition was made to the calendar of national sporting clubs by the formation of the Motor Scooter Club of America at a meeting held at Madison Square Garden last week. This sport is becoming popular in the neighborhood of the Great South Bay, L. I., and many residents are showing their interest in these original craft since Nathaniel Roe showed how to rush over the ice surface at a speed that made the sail boats look sluggish. The unusual cold of the winter has enabled the devotees of the sport to enjoy it to the fullest extent, and the new club contemplates arranging a series of races next season. There will not be much active racing this winter owing to the fact that the ice on Great South Bay may break up at any time. The list of members includes many prominent Long Islanders and New Yorkers, among them being Harry Payne Whitney, August Belmont, W. K. Vanderbilt, Jr., Jefferson DeMont Thompson, A. R. Pardington, E. R. Bellman, James L. Breeze, John Masury, Sidney Breeze, Judge Jaycock, William A. Franklyn, John Sylvester, H. H. Harrison, George Wilson and Ferdinand Rockwell.

Philadelphians Hold Annual Feast with Great Eclat.

PHILADELPHIA, March 11.—The annual banquet of the Automobile Club of Philadelphia, at the Manufacturers' Club, last Friday night, was chiefly remarkable for the rather broad hint given by Alfred T. Chambers of a coming resumption of amicable relations of the club with the A. A. A., and a return to the national fold of not only the Philadelphia organization, but of all the clubs composing the Pennsylvania Motor Federation as well. This statement, coming as it did on the heels of the recent action of the Quaker City Motor Club in appointing a committee to get in touch with the automobile clubs of the State, with a view of forming a State organization, assures, in the opinion of "those in the know," an early return of the secessionists to a place under the banner of the national organization. When Toastmaster Jacob J. Leeds introduced the Governor of the State, Edwin S. Stuart, there was a storm of applause. His Excellency paid a deserved compliment to the automobile when he stated that without it he might have been defeated. It had enabled him to attend as many as half a dozen meetings in a single night and to address thousands where, under other conditions, his auditors would have been numbered in the hundreds. He expressed himself as being heartily in favor of State

highways, and said that no better way could be devised for benefiting *all* the people of the State than by spending large amounts annually on the improvement of the roads. He promised to do all in his power to further the objects of the State's automobilists along these lines, especially in such an expenditure of the appropriations as would benefit large bodies of the people.

Mayor Weaver was at his best. An ardent automobilist himself, he could speak intelligently on the needs of motor car owners. He realized the need of automobile trunk lines, and called attention to Massachusetts' splendid roads as examples of what Pennsylvania automobilists should aspire to along this line. Turning to the speed limit problem, Mayor Weaver said he had that very afternoon, at a meeting of the Fairmount Park Commission, urged the abolition of the present seven-miles-an-hour ordinance now in force in that popular pleasure ground and the substitution of a fifteen-mile limit.

The excellent prospects of the good roads bill now before the legislature were discussed by Highway Commissioner Joseph W. Hunter. He took a shot at the toll gates, and said his plans contemplated the abolition of that bete noir of all automobilists. One of the first roads that will receive the attention of his department in this respect, he said, will be the old national highway between this city and Pittsburg.

Addresses were also made by Henry F. Walton, who told of the work of the Pennsylvania Road Makers' Association, and by Director of Public Safety McKenty, who advocated more liberal speed regulations in city and country.

Quaker Hill Climb to Be Held in Fairmount Park.

PHILADELPHIA, March 11.—City Line road, from the east end of the Schuylkill River bridge, in Fairmount Park, to the extreme top of the hill on the west bank, has been selected by the Contest Committee of the Quaker City Motor Club for its hill climb on Memorial Day. The course, which is about a mile long, with easy going at the start and finish and the hard sledding in the middle, is amply wide and sufficiently steep to afford interesting racing, while from the viewpoint of the spectator it is ideal—easily reached by trolley and affording an excellent view of almost the entire route. The last quarter is an easy up-grade to the finish at Belmont avenue. The committee has arranged a program of eight events, classifying the cars according to price.

1. For cars valued at \$2,000 and under.
2. For cars valued between \$2,000 and \$3,000.
3. For cars valued between \$3,000 and \$5,000.
4. For cars valued at \$5,000 and over.
5. American championship, open to all American made cars. To carry four passengers and complete equipment.
6. Free-for-all championship. Open to all cars.
7. Record trial.
8. Quaker City Motor Club championship. Open to all bona fide members who are not in the automobile business.

Election of the Automobile Club of Hudson County.

JERSEY CITY, N. J., March 11.—At the annual meeting of the Automobile Club of Hudson County, held at the clubhouse, corner of Clinton and Crescent avenues, the following officers were elected for the coming year: President, J. V. Z. Anthony; vice-president, John P. Landrine; board of governors, J. H. Edwards, H. T. Pond, Herbert Scott, E. M. Dixon, Dr. L. A. Opdyke.

Pennsylvania Federation Working for Its Bill.

PITTSBURG, March 11.—Active work is being done by the Pennsylvania Motor Federation in the interest of the new Motor Vehicle bill prepared by them. Twelve thousand circular letters to motorists of Pennsylvania left Federation headquarters last week asking the aid of each resident of the State holding a license to put this through. A committee is also at work at Harrisburg.

THE AUTOMOBILE CALENDAR.

AMERICAN.

Shows.

- March 18-23....—Providence (R. I.) Automobile and Power Boat Show, Infantry Hall, F. M. Prescott, manager.
 March 21-23....—Toledo, O., Automobile Show, Coliseum, Toledo Dealers' Association.
 March 21-30....—New Haven, Conn., Second Regiment Armory, Automobile Show, under the auspices of the local dealers.
 April 1-6.....—St. Louis, Mo., Automobile Show, Jai Alai Building, St. Louis Automobile Dealers' Association.
 April 6-13.....—Montreal, Canada, Second International Automobile and Sportsman's Exhibition, R. M. Jaffray, manager, 309 W. Notre Dame street.
 April 8-13.....—Pittsburg, Pa., First Annual Show of the Pittsburg Automobile Dealers' Association, Duquesne Garden.

Races, Hill-Climbs, etc.

- April 1.....—St. Louis, Mo., Auto Floral Parade, Automobile Club of St. Louis.
 April 8-9.....—Harrisburg, Pa., Two-day Endurance Run, Automobile Club of Harrisburg.
 May 30.....—Philadelphia, Hill Climb, Quaker City Motor Club.
 Oct. 19.....—St. Louis, Mo., International Aerial Race for the Gordon Bennett Prize, Aero Club of America.

Motor Boat Races.

- June 8.....—670-Mile Ocean Motor Boat Race, New York to Bermuda, Motor Boat Club of America and Royal Bermuda Yacht Club.
 July 20.....—New York to Marblehead, Mass., 270-mile Motor Boat Race, New Rochelle Yacht Club.
 Sept. 2-6.....—Jamestown (Va.) Exposition, Motor Boat Races.

FOREIGN.

Shows.

- March 7-16....—London, Olympia Commercial Vehicle and Motor Boat Show.
 March 15-23....—Edinburgh, Scottish Cycle and Motor Show.
 Mar. 24-April 1.—Prague, Austria, Automobile Show.
 April 6-13.....—London, Agricultural Hall Motor Show.
 May 4-15.....—Madrid, Spain, Automobile Exhibition, Palace of Fine Arts, Royal Automobile Club of Madrid.
 May 15-26.....—Zurich, Third Annual Swiss Automobile Show.
 June 25-30.....—St. Petersburg, Russia, Automobile Show.

Race Meets, Hill Climbs, etc.

- March 20-27....—Nice (France) Automobile Week.
 April 1-16.....—Spring Wheel Competition, A. C. of France.
 April 2-15.....—Monaco Motor Boat Exhibition and Races.
 April 21.....—Targa Florio Tour (Sicily), Auto Club of Milan.
 April 25-28.....—Touring Contest, Automobile Club of Touraine.
 April 28.....—Chateau Thlerry Hill Climb.
 May 18-21.....—Milan, Italy, Touring Club Trials.
 May 24-27.....—Voiturette Contest, Automobile Club of Austria.
 May 28.....—Isle of Man, Tourist Trophy Race, Automobile Club of Great Britain and Ireland.
 May 30.....—Isle of Man, Heavy Touring Car Race, Automobile Club of Great Britain and Ireland.
 May 29-June 1.—Irish Automobile Club Reliability Trials.
 June 3-12.....—Herkomer Cup, Automobile Club of Bavaria.
 June 14.....—German Emperor's Cup, Taunus Circuit, Imperial Automobile Club.
 June 20-22.....—American Gold Cup, Start from New York of European Tour for American Cars, Georges Dupuy, secretary, 1402 Broadway, New York City.
 June 14-29.....—Scottish Reliability Trial, Scottish Automobile Club.
 July 2.....—Grand Prix, Automobile Club of France.
 July 14, 1908....—Paris to London, Aerial Race.
 July 15-18.....—Ostend Week, Record Trials, Automobile Club of Belgium.
 July 21.....—Ardennes Circuit (Belgium).
 July 31.....—Liedekerke Cup for Touring Cars, Ardennes Circuit, Belgium.
 July 31-Aug. 8.—Belgium Regularity Contest for Touring Cars, A. C. of Belgium.
 August 1-7.....—Criterium of France, 1,750 Miles Touring Competition and 250-mile race for the Press Cup, A. C. of France.
 August 11-20....—Coupe de Auvergne.
 Sept. 1.....—Italy, Brescia Circuit, Florio Cup, A. C. of Italy.

AEROPLANISTS MAKE TRY-OUTS.

PARIS, March 5.—Notwithstanding the particularly severe winter, aero men have displayed much activity in the building shops and an impatience to practically test their new flyers. M. Kapferer brought his new aeroplane out on the Bagatelle ground, but did not attempt flight owing to a few defects discovered at the last moment and the rather unfavorable state of the weather. M. Leon Delagrange chose the military drill ground at Vincennes on the eastern border of Paris for the experimental trip of his flying machine. The Delagrange machine is similar in general construction to the latest Santos Dumont aeroplanes, consisting of a number of cells formed by a light wooden frame covered with silk. It has a total carrying area of about sixty square meters for a weight of 640 pounds. The rudder is placed in front and a 40-50 Antoinette motor drives a two-bladed propeller at the rear. The motor is of the eight-cylinder type with cylinders forming V and induction feed. Gabriel Voisin, the builder of the aeroplane, mounted the machine for the trial trip, which was witnessed by a select number of aero experts and a big crowd of Vincennes idlers. Seated on a saddle above the two wheels supporting the machine, Voisin made a good start and ran a few hundred yards at a speed of sixteen or eighteen miles an hour. The ground had been ploughed up by the frequent passage of heavy field guns and mounted troops, and under the heavy strain imposed the machine suddenly collapsed and came to a stop. Voisin's position looked dangerous, but he extricated himself without much difficulty. The motor was uninjured, but the propeller shaft was bent and severe damage done to the frame. It will probably be ten days before the machine will be ready to attempt another flight. So far as can be judged the framework is too light to stand the strain of fast travel. M. Voisin says he is certain of a successful trip.

The latest automobile constructor to enter the aero field is the Marquis de Dion, head of the firm of De Dion-Bouton. He has constructed a model of an aeroplane one-tenth actual size, and is now making equilibrium experiments with the apparatus.

AERO EXPERTS SAIL FOR FRANCE.

ST. LOUIS, March 11.—The St. Louis Aero Club will become the possessor of several new balloons this season. About a month ago an order was placed with a French builder for a varnished cotton balloon of 80,000 cubic feet capacity, to be used in the Gordon Bennett balloon race next October. The balloon will be called the *St. Louis*. Alan R. Hawley, who will pilot

the *St. Louis* in the race, has placed an order in France for a smaller balloon of 50,000 cubic feet capacity to be used by him for ascensions in and around New York. Several members of the St. Louis club are endeavoring to raise funds for the purchase of a small club balloon. If the necessary amount is obtained, the order will be placed in France. It is also possible that the balloon *United States*, with which Lieutenant Lahm won the first Gordon Bennett race, may be purchased by the club. A. B. Lambert, one of the charter members of the St. Louis club, has sailed for Europe and expects to be joined by Alan R. Hawley early in May. They will make ascensions in the two balloons

ANTOINETTE 40-45-H.P. AEROPLANE MOTOR.

under order and Mr. Lambert will endeavor to obtain the pilot certificate of the Aero Club of France. Since the Aero Club of St. Louis was organized last January, the plans for the big race in October have been practically perfected. The club has just appropriated \$15,000 to fence in the fourteen acres of Forest Park that have been granted for the use of the balloonists. Grand stands will be erected and a number of canvas aerodromes will be set up as quarters for the different nationalities entered in the contest. The balloon ground is only a short distance from the main gas works and a system of pipes has already been installed connecting the largest gas tank with the field. Four million cubic feet of gas can be supplied if necessary.

DELAGRANGE AEROPLANE READY FOR ITS EXPERIMENTAL FLIGHT ON THE DRILL GROUND AT VINCENNES.

Boston's Show a Great Record-Breaker.

If there has been any doubt in the minds of the powers that be in the various strongholds of the industry as to the exact status of the Boston show, surely the present event must have sufficed to banish it completely. Though secondary in importance from the viewpoint of the manufacturer in that it is purely a dealers' show and, in many respects, more or less local in its character, there is no show held anywhere in the country that has better justified its existence. And this despite the fact that it is perforce relegated to a time of the year when all concerned would much prefer to be able to devote their entire time and energy to other interests. More than that, Boston labors under even greater disadvantages in the matter of suitable exhibition buildings than most other cities, having to make the best of structures poorly adapted to the purpose, with an overflow situated several blocks from the main building.

The event now under way at the Hub and which will close next Saturday night is the fifth of its kind to be held there, and it will go down into history not alone as the most successful show that Boston has ever seen, but the largest aggregation of cars and accessories ever brought together in this country. If mere numbers go to make success in a thing of this kind, both the national shows held in New York and Chicago must take a back seat, for Boston has outdone them all in the matter of size and completeness. There are no less than 121 cars of different makes exhibited, so that, although it has never been accorded that title in the past, nothing of the kind ever held in the United States

can justly be said to be more truly representative of the industry as a whole, and in that respect, national, than the down-east gathering of this year.. Whether it be gasoline, steam or electric, there would hardly seem to be a well-known car made in this country that is not represented, and, true to precedent, this year's show has been productive of the usual number of newcomers, not a few of which exhibit productions of an order that may well rank with the best efforts of old-established makers. And as is to be expected in conjunction with such a notable array of cars, the showing of accessories is on a similar scale. Taken all in all, Boston and its dealers may well be proud of the fact that they have been instrumental in bringing together the most complete showing of automobile products ever assembled at a similar event anywhere in this country, and that is saying a great deal.

The Demand for Earlier Show Dates.

With manufacturers knocking the calendar all awry by bringing out their models of the following year at least six or seven months in advance, so that plenty of 1907 cars had a good chance to be old in service before 1906 expired, and starting on their 1908 product long before the 1907 touring season has even opened, it is little wonder that there is an insistent demand for much earlier show dates. Within the past two years, some of the makers have caught up with themselves and gained a lap, so to speak—they are working almost a year ahead so far as designs are concerned and if they keep on making progress at the rate that some of them have been beating the calendar, it will be no surprise to see exhibits at next winter's shows labeled, "Model of 1910."

The time when the majority of makers had to concentrate every effort for several months before the advent of the show on a few sample cars to be exhibited at the latter, and then retired to build a few more to fill the orders they had booked, has become so much a thing of the past as to be practically forgotten. Manufacturing conditions have changed entirely and the demand for time in which to build cars in order to make early deliveries possible overtops all other considerations. Hence the need for earlier shows and makers and dealers in all parts of the country are unanimous on this point. From present indications it appears that this may mean a show in the Garden in November, the Palace and Chicago shows in December, and the Boston show in January—cutting the show season practically in half.

The Dust Problem Again to the Fore.

Though it is far from being an ideal season for touring or, for that matter, one that favors the use of the automobile in any respect, there is one thing that can be said of winter, which the great majority of autoists are unanimous in hoping may some day be equally applicable to seasons of the year when the weather is not quite so rigorous, and that is its absence of dust. Winter roads are a combination of snow, ice and frozen ruts of mud that work havoc with tires and are not negotiable without the aid of devices which also tend to raise the tire bill, but above all they are dustless. What that means can only be appreciated by the rural dweller along some highway frequented by automobiles, and no less by the autoist himself, when perforce he finds himself compelled to breathe the choking cloud.

Vast sums of money are being raised in this country for the work of road building and road improvement, and in the aggregate millions of dollars will be spent in the work during the coming season in a comparatively few of the Eastern States. Experience has shown that the ancient methods of road building thus far adhered to are no better suited to horse traction than they are to the automobile. If a road is to be permanent, it must be proof against rapid disintegration, and not until steps are taken to this end will we have anything even approaching a dustless road. It is to be hoped that the large sums to be spent will not be frittered away in doing something that will shortly have to be done over again at equally great expense.

CUTLER SUCCEEDS DAY IN THE A. L. A. M.

"Owing to the continued illness and absence of George H. Day," reads the typewritten statement given out by the ruling body of the A. L. A. M. at the end of a two days' session, "E. H. Cutler has been placed in charge of the association as chairman of the Executive Committee, and enters upon his duties at once. Mr. Cutler has been prominently identified with the industry for many years, having been president of the Knox Automobile Company, Springfield, Mass., since its inception, president of the N. A. A. M. for two years, and for several years a member of the executive committee."

GILSON AND BENSON MAKE CHANGES.

Ernest R. Benson, for a number of years manager of the Boston branch of the Hartford Rubber Works Company, has been elected secretary and sales manager of the parent company, with headquarters at Hartford. J. W. Gilson, his predecessor in office, resigns to go with the Mitchell Motor Car Company, a prominent member of the American Motor Car Manufacturers' Association as sales manager.

INDIANA MAKERS AID A Y. M. C. A. PROJECT.

INDIANAPOLIS, IND., March 11.—Quite a remarkable campaign for raising funds for a new Y. M. C. A. building closed here the other day. In two weeks' time \$250,000 was raised. The success of the undertaking was due largely to the aid given by automobile manufacturers and dealers. C. E. Test and A. G. Newby, of the National Motor Vehicle Company, and D. W. Marmon, of the Nordyke & Marmon Company, contributed \$1,000 each to the cause, while Carl G. Fisher, of the Fisher Automobile Company, telegraphed a subscription of \$500 from New York City.

A. L. A. M. DISCUSSES EARLY SHOWS.

While "nothing definitely decided and nothing to make public" is the only response forthcoming to an inquiry as to what was done at last week's meeting of the Executive Committee of the Association of Licensed Automobile Manufacturers, it is a matter of common knowledge that show business was the chief thing before the meeting, and that the advisability of an earlier date was very much to the fore. It is definitely announced that the option on Madison Square Garden held by the association will be availed of and the show held there for the next two years at least, and it is further thought the next event of the kind will be in November instead of January, as heretofore. It is also understood that the matter of admissions was up for discussion, and that, owing to the cramped quarters and great demand, there seems to be little doubt but that prices will be doubled, and probably quadrupled, at least on one or two days of the week. The report of the treasurer, H. H. Franklin, showed the association to be in flourishing condition financially.

AMERICAN CARS FOR THE VANDERBILT CUP.

Entrants for the American Elimination Trial of the Vanderbilt Cup race are being announced, and an increased number over that of last year appears to be assured. The Royal Tourist, Lozier, Welch, Ford and Moon are newcomers to the 1907 list, while the repeaters will include Locomobile, Thomas, Pope, Haynes, Christie, Frayer-Miller, Matheson and Oldsmobile. There will probably be three Thomas cars, perhaps three Pope-Toledos and also three Loziers. Of course, the Ford racer will be the product of Henry Ford, and much is expected of the six-cylinder that he will bring forth. Robert Jardine again will be the designer of the Royal Tourist candidate, and Louis P. Mooers is to be the architect of the Moon racer. Mooers is well remembered as the builder of a Peerless car for the Irish Gordon-Bennett and also as the designer of the Peerless *Green Dragon* driven by Oldfield. It is understood that the Dragon and Wayne may be participants in the Elimination contest.

RUSSIA WILL HAVE FIRST AUTO SHOW.

Up to the present Russia has remained an almost entire stranger to the automobile. It would appear, however, that this state of affairs will soon be changed and that the land of the Czars may become an important field for the automobile manufacturer. The Automobile Club of Russia is organizing an automobile show in the Michel Hall at St. Petersburg, to be held from the 1st to the 17th of June next, under the presidency of the Grand Duke Michel Alexandrovitch, brother of the Emperor. Naturally, the organizing committee writes in the most glowing terms of the possibilities of the automobile in their country. The large towns such as St. Petersburg and Moscow cover a very large area. During the five months of winter horse traffic over ice and snow is very difficult, while automobiles travel about with perfect ease. On the commencement of the summer season the wealthy inhabitants of St. Petersburg remove to the islands a few miles from the city, to Peterhof, Tsarkoie-Selo, or other summer stations within a forty-mile radius, traveling into the capital every day. Locomotion is of a very rudimentary nature and the automobile would here play an important rôle. The popular idea that Russia is not provided with roads is a myth. It is certainly not so favored as France in this respect, but her highways are equal to those of the Eastern States of this country.

TAXIMETER ENTERPRISE IS CHRISTENED.

C. W. Kelsey, who is responsible for the idea of introducing the Parisian taximeter cabs to New York's streets, has just made public the name of the new concern, which will be called the American Cab and Express Company. While New York will be its headquarters, efforts will not be confined to this city, but a similar service inaugurated in other large centers, such as Philadelphia, Boston, and other large cities. Mr. Kelsey stated that the facilities of the new company will greatly exceed those at present available in Paris, where there are about 1,000 cabs on the streets. An effort will be made to do away with the overcharge and tip nuisance now so universally practised by cab drivers, a notice to the effect that the "motormen"—this is to be their title—are not permitted to accept fees, being posted inside the cab. These motormen will all be graduates of a school to be maintained at the factory. They will be thorough mechanics and capable of making all road repairs. The machines will be equipped with pneumatic tires on removable rims and a spare inflated tire will always be carried, obviating loss of time in making replacements or expense from running on flat tires.

SAD END OF A WELL-KNOWN TRADESMAN.

Leonidas Preston, for some years a salesman for the Timken Roller Bearing Axle Company, of Canton, O., and later general manager of a New York corporation of the same name, and vice-president of the Hewitt Motor Company, of this city, committed suicide on Thursday last by taking poison when about to be confronted by his business associates, William T. Timken of Canton, president of the concern bearing his name, Leonard Gray, treasurer of the same company, and Edward Hewitt, of the Hewitt Motor Company, who called upon him for an accounting. His business affairs were found to be badly tangled and he was personally heavily involved in debt, said to have grown out of a passion for betting. He was a native of Dallas, Tex., where he was born forty-six years ago, and had been identified with the automobile industry for several years through his connection with the Timken company.

THE A. S. M. E. TO MEET ON MARCH 21.

The American Society of Mechanical Engineers will hold its next meeting in the large auditorium in the society's building at 29 West Thirty-ninth street, New York City, Thursday evening, March 21. John W. Lied, Jr., vice-president of the society, will deliver a lecture on Vesuvius and Pompeii, which will be interestingly illustrated by a series of slides from photographs.

THE LEGISLATIVE BOARD OF THE A. A. A. IS NAMED.

THE personnel of the Legislative Board of the American Automobile Association is announced by President W. H. Hotchkiss. It will be noticed that on the board are included representatives of the automobile manufacturing associations including Chairman Terry, counsel of the National Association of Automobile Manufacturers, it being the belief of the executive officers of the A. A. A. that such associations and the national body of motorists can best work together, both to secure and to prevent prejudiced legislation.

Chairman Terry will shortly call a meeting of the board in New York City. At such meeting the bill recently prepared by him and introduced by Congressman Cocks will be discussed, as will also a proposition looking to the drafting of a model State motor vehicle law for submission to the State Legislatures next year. At such meeting the condition of legislation in the various States will be taken up and actively canvassed.

The legislative board is made up largely of lawyers, and, while properly not so large as the Touring Board, is quite representative of the States where the automobile is at present largely used. Its work will undoubtedly be subdivided, and, as in the case of the Touring Board, put in charge of an executive committee small in number, but thoroughly representative of the different sections of the country.

The 1907 A. A. A. Legislative Board.

Chairman, Charles Thaddeus Terry, 100 Broadway, New York City.

W. W. Niles, New York.
Sidney S. Gorham, Chicago, Ill.
Francis A. Hurlbut, Jr., Boston, Mass.
James T. Drought, Milwaukee, Wis.

Roy F. Britton, St. Louis, Mo.
M. Felton Hatcher, Macon, Ga.
Osborne I. Yellott, Baltimore, Md.
J. Jerome Hahn, Providence, R. I.
Wade Cushing, Cincinnati, O.
Robert Brown, Indianapolis, Ind.
J. B. Parkinson, Daytona, Fla.
William McL. Faysoux, New Orleans, La.
Robert Lee Morrell, New York.
D. F. Gay, Worcester, Mass.
Walter S. Schutz, Hartford, Conn.
G. Allen Hancock, Los Angeles, Cal.
James E. Cooper, New Britain, Conn.
John L. Griggs, Paterson, N. J.
Dr. F. L. Bartlett, Denver, Colo.
D. M. Ferry, Jr., Detroit, Mich.
C. C. LaForgee, Decatur, Ill.
Reuel Small, Washington, D. C.
Alexander Schwalback, Brooklyn, N. Y.
G. Douglas Bartlett, Philadelphia, Pa.
Homer H. Johnson, Cleveland, O.
F. D. Larrabee, Minneapolis, Minn.
E. W. Seeds, Columbus, O.
E. J. Kent, Pittsburg, Pa.
William H. Spear, Jersey City, N. J.
W. K. Bracken, Bloomington, Ill.
Arthur J. Plummer, Malden, Mass.
Charles H. Burras, Chicago, Ill.
D. Emmet Welch, Grand Rapids, Mich.
Carlton Godfrey, Atlantic City, N. J.
John H. Barhite, Rochester, N. Y.
William Walker Smith, Cincinnati, O.
H. H. Myers, Duluth, Minn.
George H. Wilson, Louisville, Ky.
George C. John, St. Louis, Mo. (representing American Motor Car Manufacturing Association, New York).
Giles H. Stilwell, Syracuse, N. Y. (representing Association of Licensed Automobile Manufacturers, New York).

MAKE UP OF THE A. A. A. GOOD ROADS BOARD IS COMPLETED

PRESIDENT HOTCHKISS, of the American Automobile Association, on Tuesday announced the full membership of the Good Roads Board for 1907, as follows:

Chairman, Robert P. Hooper, 509 Arch street, Philadelphia.
John Farson, Chicago, Ill.
Augustus Post, New York City, N. Y.
W. P. Murray, Cleveland, O.
E. Kneeland, Pittsburg, Pa.
William T. White, Trenton, N. J.
H. H. Trice, Norfolk, Va.
C. Gordon Neff, Cincinnati, O.
John M. Satterfield, Buffalo, N. Y.
Frank X. Mudd, Chicago, Ill.
W. R. B. Whittier, Atlanta, Ga.
W. H. Chase, Leominster, Mass.
Henry G. Strong, Rochester, N. Y.
Arthur Stein, Cincinnati, O.
Walter E. Edge, Atlantic City, N. J.
R. A. Whitney, Peoria, Ill.
William Neff, Columbus, O.
B. Clinton Slagle, Baltimore, Md.
F. A. Burrell, New York.
Joseph H. Wood, Orange, N. J.
A. E. Demange, Bloomington, Ill.
Daniel P. Ray, Olean, N. Y.
G. K. Wheeler, Kansas City, Mo.
S. W. Kent Miller, Hagerstown, Md.
George H. West, Detroit, Mich.
Palmer Abbott, New Orleans, La.
George M. Palmer, Mankato, Minn.
C. Roy McCanna, Burlington, Wis.
A. G. Widmer, Seymour, Ia.
Ben Wellie, Paducah, Ky.
Dr. F. L. Bartlett, Denver, Col.
A. J. Smith, Los Angeles, Cal.

Chairman Hooper expects shortly to call a meeting of the board for the purpose of sub-dividing its work.

The board will also doubtless take up a question at present much discussed by autoists, that is, whether they and their associations should not from this time take an open position instead of a covert one as to the good roads movement in the various States. It has often been said that owing to the early antagonism between the motorist and the farmer, the two classes of the community most interested in good roads, more would be accomplished by leaving these movements to Grange organization and legislators representing rural communities. Of late, however, it has been thought that a more open advocacy by motorists would be both wise and profitable. Chairman Hooper will present this question, and on its determination will, perhaps, depend the attitude not merely of the A. A. A., but also of its affiliated State associations and clubs in present day movements looking toward good roads.

Another subject which will be discussed will be the best ways and means to accomplish federal aid toward the improvement of at least the trunk roads in the various States.

Chairman Hooper has been named by the Governor of Pennsylvania as one of the representatives of that State at the Fourth Annual Convention of the American Road Makers' Association, at Pittsburg, this week.

An admixture of from 20 to 30 per cent. of glycerine is commonly added to the circulating water of an automobile to prevent it freezing. An automobilist, writing to *Omnia*, declares that he has obtained an excellent anti-freezing solution by the addition of about the same proportion of molasses to the water. The cost is less than glycerine and the effect somewhat better, according to the results of the experiments made.

MAKING PLANS FOR A. A. TOUR.

Chairman F. B. Hower of the A. A. A. Touring Board is confident that the annual tour for the Glidden and other trophies will be a successful event which will do much good to the general cause of automobiling. The board's executive committee will have a session to-day at Buffalo and much will be accomplished towards plans for the tour.

CHAIRMAN F. B. HOWER.

Despite the action of the N. A. A. M. executive committee in passing a resolution which could only be construed as meaning that its members should not support a strenuous competition for the Glidden trophy, there is reason to believe that the manufacturers belonging to this body will supply a goodly number of entries. The A. M. C. M. A. comes forward with the announcement that it will support the A. A. A. tour. One of its members, the maker of the Dragon, states that he will enter four cars.

Present indications point to an endurance tour starting in some Middle West city, a Sunday stop-over in Chicago, and a finish in New York City. From Boston comes the reports that the trade and clubs are not particularly interested in the tour starting from that city. A ten-day tour of 150 miles or more per day, with the Glidden trophy going to the club which supplies the greatest proportionate number of survivors in case of a tie, is what seems to meet with some general approval.

BIANCHI OWEN INTERVIEWED IN PARIS.

PARIS, March 4.—An American automobile agent who is very Italian in his preferences at present is Percy Owen, of New York, who has been in Paris a few days after a visit to Italy, and who, accompanied by Mrs. Owen, is returning to New York by the *Kaiser Wilhelm II*. Signor Owen has just come from Milan, where he devoted some time to an inspection of the Bianchi automobile factory, and he is convinced that the Bianchi is the best machine in the world. He admits that he may be slightly prejudiced in favor of the Bianchi, of which he is American agent.

"SIGNOR" PERCY OWEN.

"In America," he remarked, "nearly all Italians are just plain dagoes in our estimate of them, but I wish more of my countrymen would go to Italy and make the acquaintance of a few self-made aristocrats, like Signor Bianchi, for instance, who began twenty years ago with a hand lathe, making bicycles, and now has the finest automobile factory I ever saw. When we first heard of the Italians making automobiles we were incredulous, inclined to smile, but the truth of the matter is that the Italians are making far better automobiles than the Americans and also better than the French."

Signor Owen seems inclined to accord the term "first-class" to only one American make, and this one begins with a P. As there are several in the United States that correspond to this initial, none of the manufacturers of "P" automobiles can take offense, and all can be flattered. The qualification of "first-class," however, is used only in a comparative sense, as among the domestic products. Signor Owen was the guest at a banquet given before he sailed. Notabilities of local auto circles were present.

PARIS EDITOR ON THAT "INVASION."

PARIS, March 6.—Really, the Americans hesitate at nothing. We knew it already, but they have just given us another proof of it. They noticed that Europe, and especially France, sold them a large number of automobiles, and as they have never been able to enter any open contest, either race or competition, without receiving the most formidable slogging you can imagine, they have organized a monster contest reserved to American cars.

Well, you will say, there is nothing very stupid in that; and in what corner of America will the contest be held?

None at all; it will be in France.

What! in France? Sure. In France.

Well, if you want cheek, that is cheek. It is bad to invite yourself to dinner without informing the master of the house, but to spread abroad the invitation and not ask the host to sit down at the table is still worse.

It is Georges Prade, the fiery editor of *Les Sports*, an important Parisian journal, who, like his historic compatriot Cambonne, has allowed his feelings to get the better of him. Unlike that brave scold, however, he does not employ one word, but five columns of the first page of his journal to denounce those wicked Yankees who are daring to take part in the European tour.

The regulation and preliminary circulars regarding the tour are given in full, with numerous comments, many of them amusing, on the salient features of the project. Thus: "You see that Paris is the only town in which they will stay several days; their desire is to capture our trade and influence the public." E. R. Thomas is designated in a footnote as "the man who entices away French foremen; this time he is working at home." "The author of the scheme, after avowing its commercial object, will ask for prizes from the heads of the countries whose trade he wishes to conquer," comments the French journalist. "There is only one thing more to be done, and that is for the President of the Republic to invite the members of the caravan to dinner and wish them good luck in their efforts to capture French trade and ruin French workmen." The table of penalty points for changes of parts en route draws forth the remark that the "organizer understands American machines; he has made provision for changing everything; what matter so long as they get through."

"To take a French automobile into America 45 per cent. of its value has to be paid in custom duties, or 7,200 francs, for a medium car; if the machine is American it costs but 625 francs to bring it into France. The Americans invite the heads of the States and of the automobile clubs to witness their caravan. We invite them not to witness it, but to forbid it. We have never boycotted American machines and our races have always been open to foreigners. But to allow a contest on our roads, in our cities, before our customers, in which our machines are boycotted, with the avowed object of capturing our trade, that is not hospitality; it is idiocy."

Coming to the attack later, Prade says: "Three times we have gone to New York, and three times we have won the Vanderbilt Cup, but we never asked the Americans not to compete. Let them take part in our Grand Prix and we will lick them; let them take part in our competitions and we will lick them again; but it will be difficult to beat them in a contest, even in France, in which we are kept out."

L'Auto, a rival journal and the semi-official organ of the A. C. F., sees no reason for fear. "Why should not the Yankees have a pleasant excursion in France, drink cocktails in our country and leave their bank notes behind? If they want to capture our trade they will not wait until a Frenchman takes them on an excursion in France; they would have agents here, machines on view; they would advertise. But they don't do that, and the reason is that they are not ready. So long as they are producing their present horrors there is no cause for fear." *Les Sports* turned red with rage at this flippancy and war is now declared between the rival journals.

PROMINENT FIGURES OF THE AUTO TRADE.

R. HARRY CRONINGER, who has just taken the position of sales manager and will also have in hand the general management of the Pennsylvania Auto Motor Company at Bryn Mawr, Pa., was practically responsible for the formation of the Dayton Motor Car Company, the Ohio concern which makes the Stoddard-Dayton car, the success of which is well known. Mr. Croninger's new place will carry with it added responsibility. The Pennsylvania company is a corporation of \$200,000 paid-in capital, and its car sells for \$2,750. The company was started by Charles J. McIlvaine, Jr., of Philadelphia, a man with great confidence in the future of the automobile industry. Mr. Croninger is one of the veterans of the trade, having been formerly connected with the bicycle manufacturing industry, and, like many of its leading men, was early impressed with the possibilities and future of the automobile.

C. ARTHUR BENJAMIN, the new general manager of the Aero-car Company, also carrying the title of vice-president, is one of the pioneers of the industry. "Ben" first sold steam cars, later he became an air-cooled advocate, then next studied the more leisurely electric field, and now returns to his air-cooled proclivities. Once registering from Syracuse, later subscribing himself as from Buffalo, he now places Detroit, Mich., after his name. That smile of Benjamin's is known throughout the land, for he has sold automobiles in practically every State, and in the years gone by the thousands of good bicycles which he disposed of made him an acceptable caller when he went over more or less of his old route for the motor-driven vehicle.

JOHN G. PERRIN, the designer of the Lozier car, who is largely responsible for its originality in design and construction, is of the younger school of automobile engineers who combine a practical experience and motoring knowledge with a thorough technical education. He graduated in the technical course of the Toledo High School in 1893 and entered the shops of the Lozier company at Toledo, O., when this company was constructing bicycles, worked through all the departments, and in 1894 was detailed to superintend special work done in a temporary plant installed at Hartford during the erection of new branch works at Thompsonville, Conn. After this factory was erected, Mr. Perrin was given the position of assistant superintendent, which position he held for over two years, and in 1896 returned to the Toledo plant to superintend experimental work on small motor vehicles. From this time forward all the experimental work and designing on automobiles and marine engines was carried on by Mr. Perrin, and the Lozier steam carriage of 1897 was one of his developments. But he soon realized the position the gasoline car was destined to fill and turned his attention to it.

FIRE CHIEF BRODERICK OF DETROIT IN A WAYNE.
The chief utilizes the Wayne car in his departmental work of inspection, etc.

AUTOMOBILE EXPORTS CONTINUE TO SOAR.

For the month of January, 1907, the total value of automobiles and parts exported reached the sum of \$376,467, as compared with \$297,694 for the corresponding month of 1906. Of the former sum, \$311,242 represented the value of 214 complete cars, and \$65,225 worth of parts, the proportionate growth in these items not being evident, as the value of the parts was not stated separately prior to July 1, 1906. As usual, the largest single item is that of the United Kingdom, amounting to \$114,191, while the smallest, considering the automobile manufacturing nations, is Germany, with but \$4,806. For the period of seven months ending January, 1906, the total amount exported was \$1,438,000, as compared with a value of \$2,429,543 for the corresponding period ending with January of the present year. The latter was composed of the sum of \$2,103,556, representing 1,369 complete cars and \$325,993 worth of parts. The table for January follows:

FIRE CHIEF OF CHILLICOTHE IN HIS LOGAN SEMI-RACER.

LATEST GRAND PRIX DEVELOPMENTS

490 P

PARIS, March 4.—A question which always arises a few months before the date fixed for an important European race is how the competing machines will be started. French competitors are already asking this question regarding the Grand Prix. An answer can, of course, only be given by the racing board, and it is not safe to prophesy what their decision will be. The Dieppe circuit is only about 47 1-2 miles round and not 50 as was at first supposed. There will be 34 starters in the Grand Prix and nine in the Sporting Commission Cup, to be run at the same time, making a total of 43 cars. The minimum time possible between the start of big racing machines is one minute. A shorter interval

what they need from the stations to be built or thus leaving the main track free for passing at the It is on this side track that the Sporting Commission racers would be started.

Actual work on the circuit has not yet been begun, though the preliminary arrangements are being pushed forward. The racing board has rented a big plot of land three miles from Dieppe, on the sea leg of the course, at a spot known as Pollet. It is here that the grandstands and gasoline stations will be erected. The former will be on the seaward side of the road and will give a view of the racers running at full speed for seven miles. About four hundred yards beyond the stands is the sharp forked turn leading to the second leg of the course. It has been decided not to use this turn, but to unite the two legs by a specially constructed wide racing track built of wood, and equal to the best banked-up motorcycle tracks. Also on the coast leg of the circuit, and within easy distance of the sea, will be erected a huge camp where, for five dollars, visitors may obtain a camp bed, an evening meal and early breakfast.

PROPOSED PLAN OF SIDE TRACK IN FRONT OF GRAND STAND.

is impractical, while if a two-minute interval were adopted the first cars would be round to the starting point before the last machine had been sent off. At 6 o'clock on the morning of July 2, the first machine, a 3.3 gallon racer, will be sent away. At nine minutes past six the first Grand Prix racer will take its flight, to be followed at intervals of one minute by its companions, the last one going over the line at 6:42. Supposing that the first Grand Prix machine covers the course at the rate of 74 miles an hour, and a higher speed is not to be expected, it will be at the starting line again in 38 minutes, or at 6:47—five minutes after the departure of the last machine.

An alternative method is to start the Grand Prix racers first at 6 o'clock, at intervals of one minute, and to send away the nine Sporting Commission racers about two hours later, at intervals of two or three minutes. As the smaller racers have only to cover 310 miles, compared with 500 for the Grand Prix competitors, they would finish about the same time.

The grandstands are on the right-hand side of the road. About fifty yards before reaching them will be built a wooden side track running parallel with the course the entire length of the stands and joining the course again about fifty yards beyond the end of the stands. Machines not needing anything from the station will pass the stands at full speed on the main road. Those needing gasoline, tires, water, etc., will run on the side track and take

Grand Prix drivers have already made their appearance on the course. A few days ago Garcet ran round the circuit a few times with a 120-horsepower Bayard-Clément racer of last year's model. It is expected that some of the new machines will be on the course in a few weeks. The report that many of the racers will be last year's machines slightly modified is absolutely incorrect. In nearly every case entirely new machines will be built. Most firms, indeed, have disposed of their last year racers and are obliged to build new ones. The three Darracq flyers will closely resemble those of last year, horsepower will be 100, and the weight will remain about the same; only detail changes will be made. Bayard-Clément will construct three four-cylinder motors and will not employ the six-cylinder racers constructed last fall. The new machines will have separate cylinders, 160 bore and 160 stroke, developing 120 horsepower at 1,200 revolutions, shaft drive, and will be built rather lower than last year. It is estimated that the fuel consumption will be 5.3-4 gallons per 100 kilometers. Motobloc has under construction five racers of 170 mm. bore by 150 stroke, developing about 120 horsepower. Announcement has been made by the Belgian factory building the three Germain machines for the Grand Prix that their racers will not develop more than 80 horsepower, and will weigh about 1,200 pounds. It will be interesting to watch them against machines of nearly double this weight and power.

TARGA FLORIO ENTRIES NUMBER FORTY-THREE

PALERMO, March 1.—Italy will open the European racing season in a worthy manner with the Targa Florio race on the island of Sicily on April 21. The engagement list has just closed with a total of 43 machines, made up as follows: Italy, 4 Fiat, 4 Itala, 3 Deluca-Daimler, 4 Isotta-Fraschini, 3 Junior, 2 Diatto-Clément; France, 2 Lorraine-Dietrich, 2 Darracq, 2 Berliet, 3 Bayard-Clément, 3 Gobron, 2 Radia, 1 C. V. R.; Germany, 3 Benz, 1 Opel; Switzerland, 2 Lucia, 2 Digne. The machines will be driven by Europe's most skilled drivers, among them being Wagner and Hanriot for Darracq, and Albert Clément, Garcet and Collinet for the Bayard-Clément factory.

The Targa Florio is being run on the island of Sicily owing to the impossibility of obtaining a guarded course on the main land. Italy's war authorities last year refused to aid automobilists by loaning troops to guard the course, and in consequence seriously compromised the race season. The same policy is being pursued this year, but the difficulty is avoided by going to the picturesque island. Largely owing to the influence and liberality

of Chevalier Florio, all competing machines, together with their drivers and mechanics, are shipped free from Marseilles, Genoa, or Naples to Palermo. The prize list provides \$3,000 in cash for the winner, \$1,600 for the second, \$800 for the third, \$400 for the fourth, and \$200 for the fifth. In addition the winner will become possessor of the Targa, and every driver finishing the race will be presented with a reproduction of the cup as a souvenir. The event is a 282 miles speed contest over a 94 miles circuit of extremely varied nature. Hills are sufficiently formidable to test the climbing power of the machines as well as their brake power on the descents, a few straight stretches will allow of high speed sprints, and sharp turns will test the skill of the drivers. The regulations are simple, limiting the four-cylinder machines to a bore between 120 and 130 mm., with a weight limit of 2,200 pounds for the minimum bore; for six-cylinder motors the weight allowance is also 2,200 pounds for an 85 mm. bore, with an increase of 88 pounds for every additional millimeter bore. Last year the Targa Florio was won by Cagno with an Itala.

PACKARD WINS CALIFORNIA CLIMB.

By FREDERICK PABST.

LOS ANGELES, CAL., March 2.—The banner crowd in the history of automobiling on the Coast witnessed the second annual hill climb to-day up the mile and four-tenths grade from Pasadena to Altadena. It is estimated that 10,000 people were gathered along the road, and from the start to the finish autos were crowded under the cypress trees and palms which lined the course. Fully 500 cars took parties from Los Angeles and Pasadena for the climb. It was an ideal California day. The sun shone with all the springtime warmth, and with pretty California maidens in their summerish togs perched on the back of the tonneau seats cheering the dashing automobiles, the sight was one of which Southern California could well feel proud.

The perpetual challenge trophy, won last year by a Thomas, went to Earl Anthony's Packard runabout, driven by Bert Latham. This was the last car to run the course, and from the start, as it swept up the grade between the lines of cheering spectators, it could be seen that it was making the fastest time.

When the winning Packard crossed the car tracks a serious accident was barely averted. At this point the car was going fully forty miles an hour, and as the crossing was struck the auto seemed to leap into the air three feet. People below the spot say daylight could be seen under all four wheels. The wheels did not hit the road straight, and at the great speed it was making Driver Latham had difficulty avoiding a collision with a number of machines lining the course.

The touring car honors went to the Pope Hartford. Bert Dingley, at the wheel of the Pope, drove a beautiful race. He swung around the first turn at forty miles an hour, and sent a great cloud of dust into the air. Faster and faster the car went as it got straightened away. Approaching the car track crossing Dingley saw the immense crowd gathered there closed in, barely leaving enough room for the car to pass. It was his intention to swing to one side and take the crossing at an angle, instead of going straight, and seeing the crowd was in the way he rose in his seat behind the wheel when about 75 yards away and motioned frantically for the people to get back. There was

a rush as the crowding spectators realized Bert's intention, and as he swung across he did not miss the scurrying people by more than a few inches. The summary:

COMING OF THE EIGHT-CYLINDER ENGINE.

HARRISBURG, PA., March 9.—At a meeting of the Engineers' Club of Central Pennsylvania, held in this city last night, Cecil H. Taylor, of Martin & Co., consulting engineers, made an address on the subject of motor design particularly with reference to the multi-cylindereed motor of the future. The four, six and eight-cylindereed types were dwelt upon at length with reference to their advantages on the score of reliability, durability, maintenance and repair.

"The six-cylinder motor is but a stepping-stone to the eight-cylinder V type for higher powers," said Mr. Taylor on this point. "This latter has all the advantages over the six that the six has over the four, and, in addition, those of low cost, compactness and higher weight efficiency. The eight-cylinder, V type, can be constructed, power for power, for about 75 per cent. of the cost of the six-cylinder. Its shape and size adapts it to being placed upon the chassis more advantageously than the latter without unduly lengthening the car.

"I believe up to 50 horsepower, or say 5½-inch bore, that the four-cylinder motor will hold its own, but that beyond this power the eight-cylinder, V type, will drive the six from the field. This would mean that the eight-cylinder would begin at about 4-inch bore, giving about 50 horsepower, above which the eight-cylinder motor will be the accepted type. There are certain difficulties, notably that of carburetion, which are encountered as the cylinder number is increased beyond four. The six-cylinder motor is not only educating the public, but the constructors as well, to the point where the eight-cylinder idea can be commercially put in practice, which will not be long in coming."

HARDING TO DRIVE AMERICAN MORS CUP CAR.

H. N. Harding, who piloted the English Daimler in all its races last year, and drove the winning Haynes racer in the Vanderbilt Cup trial last fall, is the latest acquisition of the American Mors forces. Mr. Harding says that he believes the 40-52-horsepower American Mors to be not only the fastest stock touring car built in America to-day, but also, owing to its foreign materials and the extreme care in construction and inspection of detail, better able to sustain the strain of hard usage than any other American car. Mr. Harding is now at the factory, familiarizing himself with the various models and trying out new cars. No special racing car will be built, but it is planned to enter regular stock models in all open events during the coming season. Designs are nearing completion for the six-cylinder, 120-horsepower American Mors racer to be entered in the Vanderbilt Cup trial this fall.

NEW YORK PRISON TO FURNISH SIGNBOARDS.

ALBANY, March 11.—The construction of good roads and the use of automobiles have largely increased highway travel, so that the need of signboards at the intersection of highways to guide travelers is much greater than it was. Many States, and especially those of New England, have erected signboards in recent years, but the highway authorities in New York State have done little in this direction. In order that all localities in this State may be furnished with substantial signboards, Superintendent of State Prisons Collins has arranged to furnish them from Clinton prison.

AN INGENUOUSLY DESIGNED NEWCOMER

QUITE the most radical and interesting departure from current practice that was revealed at the Hub show is the Bailey runabout. This is its title in brief and it is officially known as Model B, but its full name is somewhat more descriptive of its distinguishing features. It is the Bailey revolving four-cylinder, two-cycle runabout, and for the present its builders, the recently incorporated Bailey Automobile Company, Springfield, Mass., will devote their entire attention to this type of vehicle, adding a touring car and also a commercial vehicle later, the motor taking up such a small amount of space that it is particularly adapted to the needs of the latter. The motor is the result of several years' patient labor, each step in the detail of its design having been worked out at a time until its designer was certain of it, and the result has been such as to surprise even those who have hoped most for the outcome.

Design of Motor.—As already mentioned, the chief distinguishing characteristic of the Bailey motor is the fact that it is of the revolving type, having four cylinders placed on the diameters of a circle at right angles to each other. But it has others that add to its interesting features, not the least of which is the employment of the two-cycle type of operation, and this combined with air-cooling makes it one of the simplest motors of its horsepower ever built. It will be readily evident that the working out of the design of the motor itself was complicated considerably by the

THE REVOLVING UNIT POWER PLANT

necessities of the situation in that suitable mounting presented a more or less difficult problem, and moreover one upon which the successful working of the motor depended to a very large extent. On the other hand, it simplified matters to some extent in that it permitted of easy and efficient air-cooling with a minimum of surface for radiation, and the momentum of the revolving cylinders made the use of a flywheel unnecessary. These two features have combined to make it possible to build a motor weighing but a third of one of the standard type of the same cylinder dimensions. As four explosions are obtained during every revolution and all four pistons are actuated by a single throw crankshaft which is held stationary, an unusually good mechanical and working balance is secured, with the added advantage of entirely eliminating vibration.

The crankshaft is hollow and the carbureter is attached to the end of it, the charge passing through the shaft and out through a universal cone valve to the various cylinders, all of which radiate from a common central crankcase. As the piston of a cylinder travels toward the head of the latter, a charge is drawn from the carbureter and through the valve in the crankshaft. Having finished its suction stroke, the piston closes the suction port, cutting off the supply, and the fresh charge is held in the base of the cylinder. On the down stroke of the piston the gas is forced up through a transfer passage and a balanced poppet valve into the combustion chamber on the other side of the piston, being there compressed and fired by the next upward stroke. The exhaust escapes through ports on each side of the cylinder uncovered by the piston in its descent and the same moment a fresh charge of gas is entering the same cylinder through the poppet valve in the head so that there is no possibility of mixing the spent and incoming charges.

Motor Details.—The crankshaft, the extreme shortness of which is noticeable in the illustration, is machined directly from chrome-nickel forgings and ground to exact size. It is held stationary by a steel casting resting on the cross member of the frame and also forms a support for one side of the motor. The other end rests on a large Hess-Bright ball bearing.

The crankcase is made in two pieces of manganese bronze alloyed especially with a view to obtaining the maximum tensile strength. The case is oil-tight, and, as will be seen from the illustration, the back half forms the rear support for the motor besides serving to transmit the power; it also rests on a large Hess-Bright ball bearing. Two of the latter form the support for the entire motor, while the smaller bearing of the same type held in the back of the case forms the support for the end of the crankshaft. The bearings on the crankpins consist of four rows of special ball bearings, so that there are no bearings in the engine requiring adjustment.

MINUS CYLINDERS AND CRANKCASE.

The cylinders are cast of high-grade, close-grained iron, are ground to exact size and are held on the crankcase by four 5-8 inch nickel-steel bolts having a tensile strength of 75,000 pounds to the square inch. The dimensions are 4 1-2-inch bore by 4-inch stroke and the motor develops 22-24 horsepower at 900 r. p. m. The intake pipe, valve seat and the cooling pins, of which there are comparatively few, are all cast integral with the cylinder, doing away with the necessity for using gaskets or bolts and making a most compact and effective unit. Particular care has also been taken in the selection of the iron for the pistons, which are fitted with two rings near the head and a third close to the bottom, the motor being designed to run on 70 pounds compression. Quite a radical departure from current practice is to be noted in the construction of the connecting rods, the design being known as a Scotch yoke. The pistons are secured directly to the connecting rods by means of a large nut, thus permitting

THE BALL BEARING CRANKSHAFT.

of no relative motion between the two and eliminating all side thrust of the piston on the cylinder walls. The inside of the yoke is hardened and ground and rolls on the races of the ball bearings of the crankpin, a ball or rolling surface being provided for every moving part. The use of a muffler is dispensed with by the provision of an annular expansion chamber into which the exhaust escapes. This chamber, of five times the cylinder capacity, revolves with the motor, and by reason of the low temperature at which this serves to maintain it, makes the motor extremely quiet running, as well as eliminating any back pressure. The motor is suspended on two cross members placed 12 inches apart, one of which holds it on a large ball bearing while the other carries the bracket holding the stationary crankshaft. Both its placing and features of design com-

bine to render every part of the motor accessible as none of the mechanism is behind the dash of the car. The starting crank of the motor is geared in the ratio of two to one, thus rendering starting very easy, and such as a woman can readily accomplish.

Lubrication and Ignition.—This is of the positive type, the supply being maintained by means of a force-feed lubricator of the mechanical type. The oil is forced through an aperture in the

ROD AND CRANKSHAFT ASSEMBLY.

crankshaft issuing at the crankpin, where it is first used to lubricate the latter. After leaving this bearing the oil is quickly and thoroughly distributed about the interior walls of the crankcase by means of the centrifugal force developed by the revolution of the motor. This tends to keep it at a point furthest from the center, and here there is an automatic ball check provided which, acting by reason of the same force, permits the oil to flow upon the pistons as soon as the motor begins to revolve, but prevents any from passing while the motor is at rest. Thus the centrifugal force generated by the motor when in operation is caused to act as a pump for the lubricating oil, which it is said to do very efficiently. But for this ingenious device, the cylinder that was downward when the motor stopped would become flooded with oil between the interim of stopping and re-starting the motor. The ignition is of the high-tension type, the spark plugs being placed in the sides of the cylinder near the head, current being supplied by a magneto, gear-driven directly from the motor.

Transmission Details.—The transmission is combined with the rear axle in such a manner that the latter and the engine may be placed in almost the same horizontal plane, thus eliminating the loss customary with universal joints made necessary by the angularity of the propeller shaft. The motor shaft is but 5 1-4 inches above the level of the rear axle, but is so arranged as to permit of the propeller shaft and engine shaft to be in a straight line. One universal joint is provided to take care of the angularity set up by running over rough roads. The change-speed gear is of the positive clutch type, the pinions being of specially treated nickel steel. This type of transmission, the details of which are not given by the makers, is claimed to be unusually quiet running. So much so as to make the car equally easy and smooth running on the low gear as on the direct drive—something that will be appreciated in hilly or mountainous districts. Another great advantage is to be found in its placing on the rear axle where it is installed as unit in combination with the latter. Large inspection plates are provided so that it is readily accessible without the necessity of a pit or the removal of the car body. The housing is oil-tight, and one packing of heavy grease is said to insure perfect lubrication for 1,000 miles running. For use on American roads a car must have ample clearance, and this has been borne in mind in the design of the Bailey, there being 11 inches clear between the road and the lowest part of the mechanism with 32-inch wheels. The differential is of the spur type, using four pairs of steel pinions of 1 3-8-inch face by 8 pitch; these are hardened, bronze bushed and run on 3-4-inch studs. The outer diameter of the differential case is but 8 inches, and it is made oil-tight.

Running Gear and Brakes.—The chassis is mounted on a pressed steel frame of the standard type, while suspension is by means of the usual semi-elliptic

springs in front and full elliptics of patented design in the rear. They are made of high-grade crucible steel, oil-tempered, the forward pair having five leaves each and measuring 1 3-4 by 40 inches, while the full elliptic scroll springs in the rear have four leaves measuring 1 3-4 by 36 inches. Artillery wheels having twelve 1 1-4-inch spokes and measuring 32 by 3 1-2 inches are employed; the rear wheels are made with spottings on each alternate spoke to provide for the brake drum assembly. The two sets of hub brakes provided are on the rear wheels, one of the internal expanding and the other of the external contracting type. They are lined with leather belting, and are extremely powerful, and are normally held out of engagement by mechanical means in order to prevent dragging. They are so designed as to be equally effective whether the car is running forward or backward, thus doing away with the necessity of using a sprag or other back-stop arrangement. The open construction and large diameter of the drums afford an unusual amount of radiating surface, and prevent the lining being burned out when used for severe hill work, which will be appreciated by experienced drivers.

General Details.—The steering gear is of the irreversible type, placed at the right hand side, control being by means

of an independent sector placed over the steering wheel but not revolving with it. The wheelbase is 100 inches and the tread standard, and in full running order the complete car only tips the scales at 1,500 pounds.

With the usual equipment of side and tail lamps, horn and tools, and as a two-seated runabout, the Model B lists at \$2,000, the provision of an extra rumble seat

"SCOTCH YOKE" CONNECTING RODS.

being optional with the purchaser and costing \$50 extra. The gasoline capacity is 12 gallons. Although entirely out of the ordinary run in a great many ways, the power plant of the new Bailey runabout lends itself very well to the needs of the present-day car as favored by the practically universal demand, and as will be evident from the illustration of the completed car, it differs in no way from the standard type so far as outside appearance is concerned. Its design throughout has been the subject of considerable study on the part of its builders and every part has been given a thorough trying out before adoption, so that they have every confidence in its ability not alone to do all that is claimed for it, but a great deal more.

MODEL B 24 HORSEPOWER BAILEY 1907 RUNABOUT.

THE EMPIRE TIRE CO., TRENTON, N. J.

TRENTON, N. J., March 11.—An important addition to the ranks of the automobile tire manufacturers is the Empire Automobile Tire Company, of Trenton, N. J. This company is sanguine of success. It announces its intention to make only the highest grade of goods, and for this class of goods it feels there is ample market.

CROSS SECTION EMPIRE TIRE.

It is the plan of the company, for the present, to make clincher tires only. As shown by the illustration, the Empire tire is made with raised tread. It is produced by the one cure open-steam process, which, it is claimed, produces the best quality, retaining the greatest resilience and strength in the rubber, and preventing all deterioration in the fabric.

The Empire Automobile Tire Company has the financial support of General C. Edward Murray, who is the largest stockholder in

the Empire Rubber Manufacturing Company and the Crescent Belting and Packing Company.

The president of the Empire company is Charles H. Semple, who was secretary and sales manager of the G & J Tire Com-

FACTORY EMPIRE AUTOMOBILE TIRE CO., TRENTON, N. J

pany from the time that company was organized until he resigned to become identified with the Empire.

A. Boyd Cornell, secretary of the Empire company, has been in the rubber business for many years, having been manager for three years past for the Empire Rubber Manufacturing Company. W. G. Whitlock, who has traveled for the G & J Tire Company for several years, will represent the Empire company as a general salesman.

The Empire company is arranging for a very large output of clincher tires and is also manufacturing a large line of tire sundries.

A WALTHAM COMPANY ANNOUNCEMENT.

The Waltham Manufacturing Company, Waltham, Mass., makes the following announcement concerning prices: "Commencing March 15 the extra list price will be \$100 for two-cylinder 8-horsepower motor equipped to any of the four friction-drive cars, Models BR, ER, ET and DC. Orders placed after that date will be accepted only upon that basis of catalog prices. There will be no change in list prices on 4-horsepower cars. This additional price is made necessary by the enormous increase in the cost of material and labor, together with numerous unexpected changes in construction required for the 8-horsepower motor. The cost of this motor alone, with its many improvements, is more than double the original estimate."

WHITE MODEL G, 30-HORSEPOWER RUNABOUT.

WHITE STEAM RUNABOUTS NOW READY.

It was long thought that steam did not lend itself readily to the design of car considered ideal by the buying public, but the builders of the White Steamers were not long in correcting this impression, and nothing did quite so much to dissipate it as the appearance of the Model G 30-horsepower car, both in the touring and runabout styles. The latter made its debut at the Palace show in New York City, and is now a center of attraction at the Hub's gathering. The White Company announce that deliveries are now being made of this model. The chassis is identical with that of the Model G touring car, except that its wheelbase is but 104 inches, as compared with 114 inches in the former case, and it is also geared for higher speeds. One of its distinguishing features, as compared with other cars of the same class, is the arrangement of a combination sliding and folding door at either side of the rumble seat, which adds not a little to the general business-like appearance of the machine. Back of the rumble seat accommodation is provided for baggage.

A RECORD BREAKING RUN IN THE ROCKIES.

From Loveland to Estes Park, Colorado, is a distance of seventy miles—that is, horizontally. Vertically there is a difference of 2,500 feet between them, the grades averaging 20 to 25 per cent. for long stretches, so that making this trip in a little over three and a half hours would be considered something of a feat even under the most favorable conditions. But on February 1 of this year Palmer M. Richardson of Longmont, Colo., made it in a two-cylinder 18-horsepower Reo touring car in 3:39 against a forty-mile gale of wind, and thereby hangs a record performance. The car carried four passengers and baggage, making a dead load aggregating 700 pounds, despite which the trip was made on a total fuel consumption of 3½ gallons. The wonder of most autoists in that section is how Mr. Richardson ever managed to negotiate the grades at all with so much weight aboard.

MR. RICHARDSON'S REO CLIMBING THE COLORADO ROCKIES.

LINE-UP AT THE START OF THE NEW YORK-BOSTON RUN OF THE DRAGON, WELCH AND WAYNE CARS.

WELCH WINS IN NEW YORK-BOSTON CONTEST.

BOSTON, March 13.—Three cars accomplished the winter journey between New York and Boston in a single day, but the exact distribution of the honors seems undecided at this hour. An Aerocar driven by a Mr. Robbins left New York at 12:30 A.M. Tuesday and reached the Boston show at 8:15 P.M. This car had nothing to do with the endurance contest which involved two Welch cars, a Dragon and a Wayne. This quartet left New York at 4 o'clock and L. R. Perlman reached the show at 10:45 P.M., in one of the Welch cars, though not in the one with which he started. Near Marlboro, Mass., a trolley car struck the Welch, smashed the tonneau, and R. L. Dunn, the well-known correspondent, who was a passenger, had a leg broken. The Dragon, driven by John Haynes, had a lead until near Worcester, when a broken universal joint compelled a long delay until help could be secured and repairs made. The car arrived at the Hotel Lenox at 5 o'clock this morning. Hard luck pursued the other Welch and the Wayne.

NEW MITCHELL FACTORY IN OPERATION.

The Mitchell Motor Car Company, of Racine, Wis., is getting settled down to work in the new concrete addition to the regular plant, which gives extra space of 100 by 230 feet. The new building is equipped with every modern labor-saving device to reduce the cost of handling and transferring to a minimum and

the different machines and devices are the most modern procurable. Notwithstanding this extra space at their disposal, the factory will be taxed to the utmost to execute orders for 1907 cars now on their books. As soon as the frost is out of the ground, still another new building, double the size of the one just completed, will be started and ready for occupancy about August 1. Plans are also being drawn up for a handsome new office building, which will also be ready for occupancy about this time. All buildings are to be fireproof, modern concrete construction.

G. B. Rogers, secretary and sales manager of the Mitchell company, has recently started on a business trip through the East and South to complete arrangements for the season 1908 and to open up with desirable agencies that could not heretofore be considered because factory facilities were inadequate to justify branching out after new trade.

TOLEDO WILL HAVE A SHOW.

TOLEDO, O., March 11.—Not to be outdone by her sister cities, Toledo is arranging to have an automobile show, the first in her history. The dates are March 21, 22 and 23, and the place of holding the show the Coliseum, the largest hall in the city. Local sales agents, garage keepers, manufacturers, and E. E. Fix have agreed upon the general plan to be followed out, and it is assured that a goodly display of machines will be shown. Purple and white are to be the colors of the show.

POPE COMPANY OFFICIALS AUTOING IN SNOW STORM.

Col Albert A. Pope, President, in tonneau, Charles E. Walker, second vice-president, and W. C. Walker, secretary, in front seat of Pope-Hartford Model L.

MAYOR THOMPSON OF DETROIT AND HIS MITCHELL.

This is a remarkably clear flashlight picture taken upon the arrival of the Mayor at the Detroit Automobile Show, which he formally opened.

BRIEF ITEMS OF NEWS AND TRADE MISCELLANY

Secretary F. H. Elliott, of the American Automobile Association, has just bought a Thomas Forty touring model.

The B. L. M. Motor Car & Equipment Company has opened an automobile engineering laboratory in Brooklyn under the management of David Landau. The first four-cylinder manograph ever used in this country has just been received at the laboratory.

The E. R. Thomas Motor Company is just completing a special order for twenty cars, most of which have been shipped, intended for use in and about the Tonopah and Goldfield mining districts. At the present time there are over fifty Thomas cars in use in the two mining camps.

The National Sales Corporation, of New York, has opened a branch at 1436-1438 Michigan avenue, Chicago. This move became necessary owing to the increased line of automobile appliances now handled by the company. F. J. Alvin, for six years with the American Electric Novelty Manufacturing Company, will have charge of the Western branch.

The purchase of a large majority of the stock of the Bryant Steel Wheel and Rim Company, of Columbus, O., by the representatives of the Diamond Rubber Company has given the latter control of the wheel and rim concern. The Marsh rims made by the Bryant company will now be handled by the Diamond Rubber Company as owners, and not as agents.

George E. Risley, the well known salesman of the Electric Vehicle Company, recently addressed the Rivers, Bridges and Roads Committee of the Connecticut Legislature on the advisability of having all vehicles carry a light at night. This measure has the endorsement of all State motorists and indications point to its enactment at an early date.

Enlargements are being made by The Motor Shop, of 317-319 North Broad street, Philadelphia, by the incorporation of the adjoining store at 321. The dividing wall between the old and the new is being pulled down and one large store will be formed. This concern has been handling the Stearns and the Oldsmobile, and recently added the Columbia to its line.

In these days of abundant challenges, Frank Fanning, of the Haynes Automobile Company, says he is willing to let the Haynes record for speed regularity and reliability rest upon the display it made in the last Vanderbilt race. The fact that a stock car was able to make such a wonderful showing against American and foreign autos of double the horsepower, speaks for itself.

Work on the new Winton branch in Pittsburg is progressing so rapidly that the building will undoubtedly be ready for occupancy by April 15. The structure will be one of the largest automobile establishments and the only manufacturer's branch house in Pittsburg. A site for the Winton branch in Detroit will be selected within the next ten days, and the building work will then proceed rapidly.

A marked increase in the use of electric vehicles is observable with increased facilities for charging batteries. The Electric Vehicle Company says that further stimulation has been given by the increased num-

ber of private charging plants, which are found to be not only convenient but economical. One owner of a private plant states that he ran his Columbia victoria-phaeton 3,850 miles at a cost of \$7.50.

Rainier cars will soon be manufactured at the new factory to be located at Saginaw, Michigan. The Rainier Company recently acquired a tract of land consisting of forty-six acres on which factory buildings are now being erected. There will also be a one-mile track for testing cars. Papers have been filed in Albany increasing the stock of the company to one million dollars, but the directors and management remain the same.

The Standard Fire Extinguisher Company, of Cincinnati, O., recently closed a contract with the De Luxe Motor Car Company, of Detroit, to install a sprinkler system in the De Luxe factory, the cost of which goes into many thousands of dollars. Although the original cost of the system is high, it represents, nevertheless, a profitable investment by greatly reducing fire insurance rates as a result of the increased safety element.

The Automobile Auction Company of America, Inc., has leased the building now occupied by Fiss, Doerr & Carroll Company at 41 and 43 West Sixty-third street. It is the intention of the company to hold weekly auction sales of automobiles. E. Favery has been engaged as motor expert and will examine each machine entered for the benefit of prospective buyers. J. Hatfield Morton has been retained as auctioneer of the company. The initial sale will take place the first week in April.

No reply has been received to the challenge of E. R. Thomas to match a Thomas Flyer with a British Rolls-Royce car in a run from New York to Chicago and return. One of the conditions of the test was that stock machines at present in use should be employed. The contest would have proved which were the better machines, American or British. One result, however, for the American industry will probably be that European makers will be more careful in their criticisms of American cars.

In its work toward the formation of the Society of American Motor Engineers, the committee of the American Motor Car Manufacturers' Association calls attention to the fact that the engineers in most of the factories of the Association are not mere salaried men who might flitter from one concern to another for an increase in salary, but are invariably part owners of the factories where their cars are made. In this connection might be mentioned J. D. Maxwell, R. E. Olds, Henry Ford, S. H. Mora, W. H. Van Dervoort, R. B. Crawford, L. P. Mooers, A. J. Pierce, W. Bates, James E. Austin and G. P. Dorris.

Many of the difficulties of constructional detail in automobiles have been due to designers having been influenced by their experience with stationary engines, according to David Ferguson, the Buffalo expert. This is peculiarly true in respect to oiling systems, he says, and the fact that the automobile presents entirely different conditions has been tardily grasped. Ferguson is the inventor of an efficient oiling system that was purchased by the George N. Pierce Company. It is far from being a sight feed, for the whole arrangement is under

the hood, but it works automatically and the flow of oil does not vary when the car is going up hill or down.

To test the relative value of contracting and expanding brakes, H. J. Hass, superintendent of the E. R. Thomas Motor Car Company, recently made experiments with two 1907 model Thomas Flyers. Both were fitted with foot brakes on the rear hubs of the contracting leather to metal type. For the hand lever brakes one was equipped with contracting leather to metal brakes on countershaft drums and the other with expanding metal to metal brakes in the interior of rear hubs. Starting them on a 200-yard hill with a 28 per cent. grade, the car with the metal to metal expanding brakes reached the bottom 54 seconds before the other. Further tests on straightways proved so conclusively that the contracting bands always stop the car more quickly that band brakes on the countershaft were adopted.

"Like a new half-sole to a worn shoe" is the way the makers of the "Xtra-Servis" leather treads take of expressing its value to the autoist who is undecided as to whether to have his worn out tires retreaded in the usual manner or replaced with new casings altogether. These treads are built of a special grade of leather and are secured to the tire mechanically as well as by vulcanizing, the edges being sewed to the underside of the tire lips after they have been brought around under the clinch of the rim so as to prevent rim-cutting and bursting. This is an important feature, as it also prevents the tread from loosening or bunching up at the sides. The surface of the tread is shod with a series of steel traction rivets which are insulated from the rubber by a course of leather, so that they cannot heat or cut the tire. These "Xtra-Servis" treads are readily applicable to any worn tire and are made in the usual standard sizes by the American Tire Company, Owosso, Mich., who also make the well-known Salisbury leather tires, as well as "Protecto," which is an interchangeable leather and steel tread for rubber tires and may be applied or removed in a short time whenever desired.

NEW AGENCIES ESTABLISHED.

In Buffalo, the Centaur Motor Car Company will sell the Autocar.

Sears & Burgess have opened the new St. Louis car agency, 1239 Michigan avenue, Chicago.

The firm of Banker Brothers, of Pittsburg, have taken up the agency for the Aerocar.

The F. E. Boland Motor Company, 239 Halsey street, Newark, N. J., has taken the agency for the American Mors for that city.

The tire products of Torrihon & Cie, of Clermont-Ferrand, France, will be represented in Philadelphia by William Sanford, Jr., & Company at 903 North Broad street.

Ernest Torgler, a member of the insurance firm of Braun & Torgler, of Toledo, O., will shortly open a salesroom and garage for the purpose of handling the Jewell runabout, manufactured at Mansfield, O.

The Warner Instrument Company has opened a New York branch at 1781 Broadway. A. J. Inderrieden will have charge of the branch and M. J. Dolder, formerly with the Michelin Selling Company, has been added to the selling force.

An important change in agencies is announced by the Continental Caoutchouc Company, which has transferred the distribution of Continental tires for Boston and vicinity from the Angier Company to the newly-established Boston store of the Post & Lester Company at 815 Boylston street.

PERSONAL TRADE MENTION.

E. R. Thomas, president of the big factories that build the cars that bear his name, has gone to Florida for a brief respite from business.

H. Y. McMullen has been appointed resident salesman at the Detroit branch of the Pennsylvania Rubber Company, opened on January 1 under the management of O. H. Joy.

A. D. Caldwell, formerly of the G. & J. Tire Company, and latterly with the Pennsylvania Rubber Company, has connected himself with the Atwood Garage, Toledo, O.

W. C. Whitehead, who has been connected with various large manufacturing interests for many years, has succeeded Herman Broesel as president of the Smith & Mabley Manufacturing Company.

George C. John, sales manager of the St. Louis Car Company, and a member of the Legislative Committee of the American Motor Car Manufacturers' Association, has been appointed on the Legislative Board of the American Automobile Association.

A. W. Church, secretary of Wyckoff, Church & Partridge, is satisfactorily recovering from the accident he met with some time ago when thrown from his carriage. Mr. Church has gone South to recuperate and has taken to fishing as a pastime.

Thomas Henderson, vice-president of the Winton Motor Carriage Company, accompanied by Mrs. Henderson, left Cleveland this week on a leisurely trip to the Pacific Coast. Going and returning, Mr. Henderson will visit Winton representatives in the larger cities of the West.

J. B. Bartholomew, president of the Bartholomew Company, makers of Glide automobiles, recently returned from a three months' trip to South America, which he visited to establish agencies for Glide cars, besides attending to some of his other business affairs in Argentine Republic, where he has some vested interests.

RECENT TRADE REMOVALS.

D. W. Romaine, agent for Marion, Queen and Durvea cars, has removed to a two-story fireproof building at 225-7 Mercer street, Jersey City, N. J.

The De Barrès Auto Company, agents for Delahaye and Pilain automobiles, will shortly occupy the handsome showrooms at 1966-8 Broadway, between Sixty-seventh and Sixty-eighth streets, about to be vacated by the C. G. V. Company. The present De Barrès garage at Park avenue and Sixty-third street will be retained and undergo considerable improvements.

RECENT TRADE PUBLICATIONS.

There is an element of assurance about the new books just issued by the National Motor Car Company, of Indianapolis, Ind. It consists of sixty-four pages of letters from National owners in every part of the Union, all testifying to the good qualities of this well-known machine.

"From the Intake" is the title of a neat little booklet that is being circulated by the Aerocar Company, of Detroit. On the cover is a design showing an intake pipe from the big Model F touring car. It is disconnected from the motor and the contents of the book are supposed to be coming from the intake.

APPLIANCE COMPANY FORMED.

Incorporated with a capital of \$125,000, the Willyoung Appliance Company of Yonkers, N. Y., will undertake the manufacture of coils, magnetos, spark plugs, speedometers, odometers, and similar accessories for motor vehicles and motor boats. The president and manager is Elmer G. Willyoung, a man who has had extensive experience in electrical matters. Mr. Willyoung is a floor member of the American Institute of Electric Engineers, and has been president of the electrical section of the Franklin Institute of Philadelphia. He originated the vacuum process of manufacturing coils, devised the apparatus used by the Postal and Western Union Telegraph Companies for testing and locating faults in cables, and for some time was the electrical expert to Queen & Company, of Philadelphia, and to the Franklin Engineering Company. Associated with Mr. Willyoung will be Benjamin Briscoe, J. D. Maxwell, Jerome Bradley, R. A. Paterson and a number of others.

WILL NOT AMALGAMATE.

The Acme Motor Car Company, of Reading, Pa., states that there is no foundation whatever in the report that the Duryea Power Company will be incorporated with that concern. The Acme Motor Car Company is being reorganized, but business has never been stopped.

RECENT INCORPORATIONS.

Bowly Auto-Pneumatic Tire Company, Jersey City; capital, \$100,000. Incorporators: William W. Gooch, James B. Mackey, and Ralph B. Crummy.

Mercantile Motor Car Company, Brooklyn; capital, \$50,000. Directors, C. P. Wormwood, 350 Eighth street; B. L. Lumpkin, and I. H. Smart, Brooklyn.

Rockaway Auto Garage Company, Queens Borough, New York; capital, \$10,000. Directors, A. G. Jennings, C. B. Ebert, and J. T. Curtis, Rockaway Beach.

Franco-American Lamp Company, New York; capital, \$5,000. Directors, Nicholas Leewenstein, 157 West Fifty-fourth street; C. S. Hoffman, New York; Leopold Herzstein, Brooklyn.

TESTING LOGAN CARS ON ONE OF THE PICTURESQUE ROADS NEAR THE FACTORY, CHILLICOTHE, O.

INFORMATION FOR AUTO USERS.

Repairing a Puncture by Old-Time Methods—the kind that proved effective with the bicycle tire, but have fallen so far short of it in the case of its large successor, is a job to try the patience of a saint, particularly when, after all the fussing with patches and cement has been gone through, the patch fails to

"CINCH" TIRE REPAIR KIT.

hold, and the operation must be repeated before many miles have been covered. As an improvement on this process the Auto Goods Company, 60 State street, Boston, Mass., have brought out the "Cinch" tire repair kit, which enables the autoist to make a positive and permanent repair in a fraction of the time required to put on an old-time patch. The complete kit consists of but three tools, a cutter, wire opening tool, and a pair of pliers, in addition to a supply of puncture repairing seals. Inner tubes have been known to give 2,500 miles' service after having been repaired with "cinch" seals.

Hydraulic Oil Clutch.—The Palmbla hydraulic oil clutch has been designed by the North Chicago Machine Company to eliminate the use of speed transmission, except reverse, and give an apparatus with which the car can be run on high gear from one mile per hour to the highest speed of the motor. It consists of a flywheel clutch body bolted to the crankshaft of the motor, taking the place of the flywheel. One and a half to two quarts of oil are poured into the clutch casing through an oil space provided for that purpose. When power is applied to the foot lever a

PALMBLA HYDRAULIC OIL CLUTCH.

couple of wedge shaped rings move in opposite directions and force a flange ring inwardly. This acts upon two studs, an auxiliary ring and a cone ring, and causes the latter to follow a slot in piston blade and draw the same towards center or until the blades are flush with

the piston ring. There being then no obstruction to the oil it passes freely round with the flywheel, allowing the driven shaft to remain stationary. Power is applied on releasing the foot pedal, which action confines the oil between the blades within the clutch casing and causes piston rings to revolve with the flywheel. More or less power can be applied according to the control of the foot lever, the gradual advance of the blades towards the outer wall of the flywheel being proportionate to the power transmitted through the clutch to the car.

Nutting Machine Company, Dayton, O.—Under the title of the "Nu Zent" this concern is just placing a novel carbureter on the market. Although it is based on the fundamental principles of carburetion as established by experience during the past several years, it com-

SECTION VIEW OF NU ZENT CARBURETER.

bins them in a somewhat different manner, and in its design embodies some that are quite new. For instance, the level of the float is adjustable from the exterior. Its construction and operation will be evident upon reference to the cut showing it in section. The suction at H causes fresh air to enter at L, producing suction at the spray nozzle and spraying the gasoline against the cone A; the gasoline and air are drawn round the sharp outer edge of the cone and are then thrown against the corrugated surface of the inner side of the auxiliary valve B, from there passing through H to the engine. When the normal air supply is insufficient, the valve B is lifted by the vacuum, causing additional air to enter at J—a port extending around the entire circumference of the carbureter. The valve B lifts in accordance with the speed of the engine; thus making the opening between the cone and the under side of the valve proportionately greater as the speed increases, and insuring a uniform mixture at all speeds.

H. P. Electric Ignition.—The Auto Novelty Company, of Milwaukee, Wis., has purchased the rights for this country of the recently-imported H. P. Electric Ignition System. The "Sure Thing" spark plug has been designed to abolish the

"SURE THING" SPARK PLUG.

nuisance of fouling and short circuiting. Its manufacturers claim that even a continuous flow of oil will not affect its efficiency. A superior quality of imported insulating material is used in its construction, and the metal parts are finely electro-copper-plated, nicked and polished.

Improved Tire Inflation.—Like everything else in connection with the automobile business, the matter of tire inflation has come in for its share of attention and improvement, with the result that we now have, in place of the arduous hand pump, a small portable tank containing a mixture of CO² gas and nitrogen, which is liquefied at a temperature of from 65 degrees to seventy degrees under a pressure of about 750 pounds. This gas on being released from the pressure immediately regains its gaseous form and is perfectly dry and beneficial to the rubber. Plain CO² or carbonic acid gas has a tendency to filter through the infinitesimal pores of new rubber, and while after the first filling the tires will hold up, the best results are obtained when a little nitrogen is included in the mixture. In filling the tires with compressed air a goodly amount of moisture finds its way into the inner tube, and it is this moisture which sooner or later causes the tire to rot and crack. This gas being a preservative of rubber adds greatly to the life and resiliency of the tire. Another valuable feature is uniformity of pressure. This result can only be obtained where the source of supply is at a constant pressure (the gas being in liquid form, the pressure is always constant) and when the pressure is measured by a reliable gauge. The gas is not in any way inflammable or explosive. The apparatus, complete with gauge, fastens to any convenient portion of the car and weighs a little over twelve pounds; it fills a tire in about five seconds and inflates from twenty-five to thirty tires. Tanks can be recharged or exchanged in any large city, and can be procured direct from the manufacturers, the Standard Carbonic Company, Cincinnati, Ohio.

A Duplex Radiator.—A disadvantage of water-cooled engines is that any accident to the radiator, owing to frost, defective material, bad workmanship or other cause, frequently puts the automobile entirely out of commission. To prevent this the Duplex Radiator Company, of Detroit, Mich.,

FRONT VIEW OF DUPLEX RADIATOR.

has produced a double radiator consisting of two halves which work singly or as a unit. Ordinarily, the entire radiator is in use through double-ended inlet and outlet pipe fitted with four valves. When either half of the radiator leaks, the valves are closed and the defective half is removed for repair, while the remaining half continues in use. Also, during cold weather, when one half of the radiator is sufficient, the remaining half can be freed of water. Another feature of the Duplex system is a by-pass by the use of which, should the pump fail, a water circulation is assured by thermo-syphon.

Gabriel Shock Brake.—The structural feature of the new Gabriel shock brake are two steel springs separated at their extremities by a steel block and securely bolted together. The lower extremity fas-

DETAILS OF GABRIEL SHOCK BRAKE.

tens under the clip of the spring by an angle steel plate. Between the two sides of the spring is a double steel plate securely riveted to a stud which extends

through a slot in the side of the brake nearest the frame and attaches thereto. These double plates are recessed so as to firmly hold a friction composed of camcl's hair belting which bears against the inside of the side plates. In addition to the steel blocks used at the upper and lower extremities, there are also inserted thin steel washers which, when removed, bring the two sides closer together, thus securing greater retarding force. Whatever slight longitudinal motion there may be is provided for by the attachment of the clip by a bolt to the bottom of the brake. Side motion of the car is provided for by making an elongated hole for the bolts which bind the side plates at the top, thus allowing each side plate to move independently of the other. The open space between the two sides of the spring is protected by a thin steel strip which gives the article a handsome appearance and prevents mud and dirt from entering the brake. The shock brake is light, compact and substantial and may be adjusted to either elliptic or semi-elliptic springs. It is made in three sizes by the Gabriel Horn Manufacturing Company, of Cleveland, O.

A Combination Switch.—The Pittsfield combination switch is of the click type, provided with a neutral point, A, in the fiber ratchet C. It has also a contact point or projection, D, which forms a part of the circuit when engaged with the spring-actuated steel plunger I. This

SECTION NEW PITTSFIELD SWITCH.

steel plunger is integral with neutral binding post O, thus forming a part of the circuit only when the fiber ratchet is in the position as indicated by bottom

TOP VIEW PITTSFIELD SWITCH.

view of switch in the drawing. This point of contact can readily be found by the operator, who knows how many clicks to count from the neutral point A in either direction. On the other hand, anyone not familiar with the combination will be unable to establish a circuit. The contact lever G is a fixture on the switch and is not detachable. The knob H serves a thumb piece for rotating fiber ratchet O for the purpose of either opening or closing the circuit. The neutral binding

post connected directly to the units or coils is represented by O. The battery binding post is shown by M. This bind-

BOTTOM VIEW, SHOWING CONNECTIONS.

ing post is represented on the face or outside of the switch by the contact steps K and L.

Divided Wind Shield.—A glance at the accompanying cut will explain the nature of the Beecher divided wind shield now being constructed by the Limousine-Carriage Manufacturing Company, of Chicago. The shield was put on the market to meet the demand for something cheaper

BEECHER DIVIDED WIND SHIELD IN PLACE.

than the "Schildback." It has the same light center bar, but is hinged on this model. The small wheel which shows at the top of circle when glass is raised is on a bolt fastened to top frame and has a 1 1/2-inch stem with a loose washer next to the circle. By simply loosening these two wheels the shield can be folded, but it can also be stopped at any angle, and if the

BEECHER DIVIDED WIND SHIELD FOLDED.

lamps are in the way can be held perfectly rigid so as to clear them. All fittings and rods are solid brass, the frame is bound with half-oval polished brass, bottom boards are left six inches wide so they can be cut out to fit any shape dash. Size of frame is 40 by 33 high, allowing two inches between glass and dash. It is made in mahogany finish, natural ash or black.

THE AUTOMOBILE

AEROPLANE WITH 100-H.P. EIGHT-CYLINDER MOTOR

PARIS, March 12.—In the quiet peacefulness of St. Cyr, near enough to the capital to obtain all necessary supplies, but far enough removed to be free from the visits of the idler about town, Alberto Santos-Dumont is working the Union ten hours a day on his new aeroplane. Yesterday was a holiday and a select reception day, the doors of the big wooden shed being thrown open and the new *Bird of Prey* brought out on the military cadets' drill ground in the presence of a number of officers from the engineer corps at Versailles and a small body of aeronauts. No attempt was made at flying, the machine, though apparently ready for a trip, needing the addition of a number of small but important parts and the engine requiring some attention.

Santos-Dumont has profited by his past experience, the new flyer being a great improvement over the one with which he won the Archdeacon Cup for covering a distance of 220 meters in the air. It consists of two box-kite wings placed at an angle of eight degrees, having a spread from tip to tip of 42 feet. Their width is only 24 inches. All the canvas parts have been replaced by thin polished wood and the frame work is of light mahogany. The central frame is metal, the rear frame on which is mounted the rudder being of bamboo with metal stays. Total weight is 40 pounds less than that of the last flyer, *No. 14 bis*.

The most curious feature of the flying machine is that the motor, a 100-horse-power eight-cylinder Antoinette, is placed above and in the angle of the two wings. Metal stays, not shown on the engraving, will be carried up above the motor and will support the gasoline tank at the highest point. The two-bladed 78-inch alumi-

num propeller is placed in front of the apparatus. Santos-Dumont will be seated on a motorcycle saddle attached to the rear stay below and immediately behind the engine. He will sit in the attitude of a rower, with his legs stretched out on a small metal platform. Controlling levers will be immediately in front of the steersman. Instead of the pair of bicycle wheels, which always broke when the machine came down to ground, a single pneumatic wheel of small diameter but big bearing surface will be employed. Thus the machine will be very near the ground during its preliminary canter. To protect the pilot when running at high speed a celluloid wind shield will be fitted. It will only have a small area, as, owing to the position in which he is placed, the pilot will offer little resistance to the wind. The rudder of the new machine is placed in the rear. In addition there will be two

small lateral rudders to give a better equilibrium and aid in turning. As a matter of prudence the aeroplane will be equipped with a speed indicator so that the action of the rudder causing the machine to rise in the air may not be given until a sufficient speed on the ground has been attained. Thirty-seven miles an hour is the speed necessary before flight will be attempted.

Santos-Dumont declares that he has every confidence in the ability of the aeroplane to win the \$10,000 prize of the Grand Prix de l'Aviation, the conditions of which are that a one-kilometer circuit shall be covered at a distance of not less than three feet from the ground. In about a week the machine will be completely terminated and as soon as the drill ground is sufficiently dry and weather conditions favorable flight will be attempted.

SANTOS-DUMONT INSPECTING GROUND WHEEL ON HIS NEW AEROPLANE.

SANTOS-DUMONT'S FIFTEENTH FLYING MACHINE NEARING COMPLETION IN HIS WORKSHOP AT SAINT CYR.

M. Vuia, who commenced aeroplane experiments long before Santos-Dumont, has at last attained a certain amount of success. On the Bagatelle ground, in the Bois de Boulogne, several attempts were made this week. The first time the machine took a short jump only a few inches from the ground. On the second flight the machine rose four feet from the ground and traveled thirteen or fourteen feet. On a final attempt being made thirty or forty feet were covered at an increased height from the ground. M. Vuia is the second person in France to accomplish a successful flight on a heavier than air machine. Defects discovered in the aeroplane are its lack of equilibrium and a slight inefficiency in the 12-horsepower carbonic acid motor. On striking the ground one of the road wheels of the aeroplane was buckled up, thus preventing further trials for the present. It is interesting to note that the carbonic acid engine was designed by the late Leon Serpollet. In appearance the aeroplane resembles a bird with its wings extended. It is supported on a four-wheel frame, raising the wings about five feet from the ground.

Henri Kapferer has tested his new aeroplane built for him by Voisin Frères, and provided with a Buchet eight-cylinder engine. The trial took place on the Sartrouville plain, near Paris, but no attempt was made to rise from the ground.

De la Vaulx Finds Tobogganing Dangerous.

Comte Henry de la Vaulx, the well-known aeronaut, has been the victim of an unfortunate accident resulting in a broken leg, while tobogganing at Caux, Switzerland. He has been removed to the hospital of Saint-Jean-de-Dieu at Paris and is progressing as satisfactorily as can be expected. Owing to the complicated nature of the fracture, however, it is thought that it will be some time before the Count will again be able to take part in his favorite sport, and his chances of being able to participate in the Gordon Bennett balloon race at St. Louis are somewhat remote.

ITALY BARRED FROM BALLOON CUP RACE.

President Cortlandt F. Bishop, of the Aero Club of America, Monday received word that the International Aeronautic Federation had decided against the acceptance of the two Italian entries for the Gordon-Bennett Cup, same having been filed after the official closing of the entry list.

Lieut. Frank P. Lahm, last year's Cup winner, is to take charge of a government balloon station at Fort Leavenworth, Kansas, to be established there by the War Department.

MICHELIN TO OPEN AMERICAN FACTORY.

American tire manufacturers are to have a formidable competitor in the Michelin concern. M. Edouard Michelin, one of the heads of the great tire manufacturing company of Clermont-Ferrand, France, who has been in America for the last three weeks, announces that an American Michelin tire company has been incorporated with a capital of \$2,000,000. The new company has purchased an important rubber plant to which large additions will be made at once. A staff of expert workmen will be brought over from the French factory and the methods employed at Clermont-Ferrand will be followed closely in the American works. It is expected that the first Michelin tires constructed in this country will be ready to put on the market next September. By constructing in this country Michelin will save the 35 per cent. for freight and duty and will be able to sell at the same price as the American makers. M. Edouard Michelin, who has made all the arrangements for the American factory, is technical director of the main factory at Clermont-Ferrand, employing 3,000 workpeople and making 1,000 tires a day. In addition, the company has a factory in England making 500 tires a day, and one in Italy. M. Michelin sailed for France yesterday.

UNITING THE HOUSES OF CHARRON-CLEMENT.

A cablegram from Paris announces the approaching marriage of Fernand Charron, the founder of the G. G. V. firm, with Mlle. Clément, daughter of the head of the great Bayard-Clément factory, and sister of Albert Clément, the well-known racing automobilist. Fernand Charron was three times the champion cyclist of France, won the first Gordon-Bennett race, founded the G. G. V. firm in 1901, and retained the position of general manager when the company was floated as a limited liability company last year under the title of Charron, Limited. Lately he has paid much attention to race horses, being successful as a gentleman rider in a large number of contests. Mlle. Clément is a well-known figure at all automobile races, for she makes a point of witnessing every race in which her brother is engaged. Her father, Gustave Clément, thirty years ago a bicycle maker employing one man and a boy, obliged to sell his first machine before he could start on the second, is now one of the richest men in France. In addition to his huge factories near Paris and at Mézières in the Ardennes, he has large interests in the Michelin tire factory and the Panhard concern, and is the financier of the lessees of the National Opera house at Paris.

FIRST BANQUET OF THE AERO CLUB OF AMERICA

THE first annual banquet of the Aero Club of America was held at the Hotel St. Regis, New York City, Thursday evening, March 14, 1907. The function called attention to the fact that there exists in this country a substantial organization of over a hundred members, the object of which is to advance the development of the science of aeronautics and kindred sciences, and to encourage and organize aerial navigation and excursions, conferences, expositions, congresses, and races. Orville and Wilbur Wright, the famous Ohio brothers, were expected guests of the occasion, but it was announced by President and Toastmaster Cortlandt F. Bishop that these two noted aeronauts were modest in such degree that it could not be conceived of in New York. Nevertheless, a letter was read from the Wrights wherein they reiterated and emphasized the claim that they have successfully solved aeroplane traveling.

President Bishop gave greeting to nearly 200 participants in the banquet, which had some excellent oratorical talent, even though in several instances brevity was to them an unknown quantity. The Gordon-Bennett trophy, which Lieut. Frank Lahm last year won for America, divided attention in the center of the speaker's table with the Aero Club Cup.

It so happened that the annual dinner of the Aero Club of France was held on the same night as that of the Aero Club of America, and cablegrams of best wishes were exchanged between the two organizations. The health of Lieut. Lahm was drunk standing during the playing of the National air. A message from the lieutenant was greeted with much applause, and, all in all, the occasion was one of intense enthusiasm and exceeding optimism regarding aerial flight. President Bishop announced October 19 as the date of the balloon race at St. Louis, and five countries will participate. Preparations for this great international event are progressing favorably.

President Bishop introduced James E. Smith, president of the Business Men's League of St. Louis, as the first speaker. Mr. Smith described the plans made for the big race, for which the city will furnish free gas, soldiers, and four extra prizes.

Colgate Hoyt, president of the Auto Club of America, followed. He pointed out a few of the advantages aeronauts had over autoists. The aeronaut had no tire troubles, and there were no spotters up in the air, where the coast was clear.

President Tucker of the Jamestown Exposition talked of the plans being made for aeronauts to visit Jamestown this summer, where there would be an aeronautical congress from April to November, with a recess to allow all hands to visit St. Louis. He declared that when they visited old Virginia they would not want to leave it.

McCready Sykes told many stories that put his audience in good humor, and E. B. Bronson described the first trip made in a dirigible balloon in this country, 'way back in 1863, when a machine built by Dr. Bartholomew Andrews sailed from Perth Amboy and made thirty miles in 14 1-2 minutes. Dr. Andrews experimented for years, and on June 21, 1849, had so far perfected his machine that he advertised in the New York *Sun* an exhibition to take place on July 4, and charged 50 cents admission for one man and two women. This ascension was not a success, because the steering apparatus did not work well.

The Hon. John S. Wise told of a famous ascension which he once made—in a dream—and descanted on the glories of Old Virginia. Burgess Johnson contributed some more humor, and then Anthony Fiala, the noted Arctic explorer, gave one of the most interesting talks of the evening, accompanying it with some excellent moving pictures. Mr. Fiala had some doubts as to the success of Mr. Wellman in utilizing the airship in reaching the North Pole.

PROMINENT AUTOMOBILISTS WILL BE NOTICED AMONG THOSE PRESENT AT THE HOTEL ST. REGIS, THURSDAY EVENING, MARCH 14, 1907.

LAUNCHING LA RAPIERE II. FROM THE TELLIER YARD BELOW AUTEUIL VIADUCT, PARIS.

LA RAPIERE II. A NOTABLE MONACO ENTRANT

PARIS, March 11.—There is tremendous activity among the numerous contestants in the Monaco motor boat meet to open on April 1. At every building yard of importance on the Seine in the neighborhood of Paris and in a few of the southern ports where motor boats have taken some hold work is being pushed forward as fast as possible to be ready for the opening of the meet. Although Paris is a considerable distance from the sea and on a river offering but meager facilities for fast motor boat work, it is in the neighborhood of the capital that the majority of the Monaco racers are being built. The grouping of the important French automobile factories around Paris is probably responsible for this.

At the Tellier Fils & Girard yard, just outside the city walls, *La Rapière II.* was launched this week and underwent trials on the straight stretch up to Billancourt. *La Rapière* is the worthy successor of the original *Rapière*, also built by Tellier Fils & Girard and engined by Panhard & Levassor, which carried all before her in the eight-meter class. Richard Brasier, with the famous but unfortunate *Treffe à Quatre*, was the first in France to produce a motor boat which attracted public attention for its remarkable speed. That was in 1904. The following year *La Rapière* was on everybody's lips, for she proved herself the fastest all-round boat produced up to that date. In her own class she was unbeaten and even in the open races against such monsters as the 300-horsepower *Dubonnet* and the *Panhard-Levassor* she was a most formidable rival. *La Rapière II.* is looked upon as quite as dangerous as her predecessors.

Other boats nearing completion at the Tellier yard are the *Mouvette* and the *Panhard-Tellier*; in addition the firm will be

represented by Baron de Cater's *Seasick*, a craft which showed a remarkable rate of speed last year.

The Pitre yard at Maisons-Laffitte, on the Seine, is remarkably busy. Vincenzo Florio's steel boat, *Mercedes-Florio*, is receiving very close attention and should be ready to take the water in about a week. *New Treffe II.*, to carry a Brasier motor, and an unnamed boat for Henry Fournier, equipped with an Itala motor, are on the stocks side by side with a small fleet of cruisers. Pitre has probably turned out more racing boats than any other firm in France.

Comte de Lambert's hydroplane, *Glisseur*, was added to the list of entries for Monaco at the last moment, thus providing a companion for the *Nautilus-Obus*.

TENNESSEE STATE HIGHWAY PROJECT.

MEMPHIS, TENN., March 18.—The inspiration of the east has reached the western section of Tennessee, giving its habitants also a hankering for good roads. The legislative council of the city of Memphis will be asked to co-operate with Nashville and other important cities in the State to establish a system of State highways. A bill contemplating the preliminary plans for such a system of roads has been prepared and will be introduced immediately after the recess. Despite the steady progress which has been made in the Central and Eastern States in favor of good roads, the South has up to the present remained indifferent. The bill which the city council will be asked to support only asks for a sufficient appropriation to cover the expenses of a preliminary tour. The idea is to connect Memphis with Knoxville by a State road.

OLYMPIA COMMERCIAL MOTOR SHOW

LONDON, March 9.—John Bull's ample chest swelled with national pride when the Lord Mayor of London came in all his official dignity to open the commercial vehicle exhibition in the banner bedecked Olympia Hall. His pride is not vain vanity, for the British motor constructor has indeed made enormous progress in the development of the automobile for commercial purposes. What pleases the Britisher most of all is that the Olympia show is British. The technical man knows that many of the engines are imported, that he has still to deal with Panhard & Levassor, De Dion-Bouton, Renard, Dietrich, Lacoste & Battemann, Darracq-Serpollet, and a host of others whose domicile is on the banks of the Seine; he knows that most of his big fleet of noisy, smoky omnibuses are made in Germany, and that France is not altogether foreign to their birth. But John Bull looks only at the labels which are All British. There is room for national pride, for the assembly of commercial vehicles is much more British than any other group of automobiles ever assembled in public exhibition in the metropolis. When Continental countries were profitably engaged in constructing high-grade pleasure cars and organizing impossible races the Anglo-Saxon was quietly occupying himself with the motor for business purposes. There were many disappointments and heavy losses between 1899 and 1901; from 1902 to 1904 there was steady improvement; at the end of 1904 the Heavy Motor Car Order gave an impetus to the industry by legalizing five-ton wagons and tractors and permitting the use of double-deck omnibuses. Within eighteen months London has added 250 steam wagons and tractors and 800 motor 'buses to its effective means of street transport.

It was owing to this extraordinary development that the management of the Olympia show decided to reserve last November's event entirely to pleasure automobiles and to hold a separate

show in the same building for all classes of commercial automobiles, motor boats and accessories. The success of the show just opened proves the wisdom of the decision. There are eighty stands on which are shown light and heavy delivery vehicles, omnibuses, etc. The total number of exhibitors is 250. Grouped in the main hall are the various classes of commercial vehicles and machine tools. In the annex are the motor boats, and the galleries are reserved for tires and accessories. The decorative scheme is the same as was employed for the November Olympia show.

Gasoline motors are in a large majority for everything except the heaviest work. British firms are more numerous than the united foreign houses, though the latter still present a strong front, with such well-known names as De Dion-Bouton, Delahaye, Dietrich, Fiat, Gobron-Brillié, Isotta-Fraschini, Hotchkiss, Mercedes, Mors and Berliet.

Steamers are a very good second. Excepting the Darracq-Serpollet combination, all the exhibitors in this class are of British origin. Steam has always been a favorite in this country, and although gasoline has secured first position for light and medium class work, it has been unable to oust its older rival or even successfully compete with it for powerful hauling. There is a certain amount of discussion among users of steam haulage on the relative value of steam wagons and tractors hauling a number of trucks. A tractor will cost about \$2,250, while a steam wagon capable of doing the same amount of work would call for the investment of \$3,500; but as the former must be completed by a number of trucks, there is but little difference in the total cost. Where regular five-ton loads can be furnished the steam wagon complete in itself seems to offer an advantage. The tractor is generally more profitable where varying loads have to be dealt with. Cost of maintenance, including driver, interest,

GENERAL VIEW OF THE OLYMPIA, LONDON, IN WHICH THE FIRST BRITISH COMMERCIAL VEHICLE SHOW IS BEING HELD.

FIAT FIVE-TON 40-HORSEPOWER TRUCK.

wages, stores, maintenance, depreciation and insurance, is generally the same in each case, \$25 a week being an average sum for a five-ton wagon.

Electric vehicles are a very meagre class. The British business man has no faith whatever in electricity as a factor in commercial delivery work. Where slow speed and big hauling power are

BRITISH 40-FOOT SEAMLESS STEEL BOAT.

needed he employs steam, where he wants quick service he uses gasoline. Between the two there is no room for electricity. Of the four electric vehicle firms two show light vehicles, ambulances, etc., and two others, Greenwood & Batley and the British Thomson-Houston Company, have gasoline-electric vehicles.

Among the special features of the show are the number of omnibuses to be used by railroad companies for station work and

STRAKER-SQUIRE GASOLINE-ELECTRIC 'BUS.

as feeders in districts where the iron rail has not penetrated. Practically every important railroad company in England has adopted gasoline 'buses for use from their depots. Tramway companies, too, have taken up this class of vehicle as feeders and connecting links to their different termini. Rollers and lawn mowers are being given more attention than ever before. Whether used for road making, rolling or cutting grass, they are all operated by gasoline motors. The Renard train, the invention of the late Colonel Renard, attracts considerable attention. The train is not new, but it has only recently been introduced to England, and will shortly be constructed in the Daimler factory at Coventry.

In the marine section of the exhibition there are thirty-five firms, compared with twenty-nine at the show held fifteen months ago. Excepting Panhard-Levassor, Delahaye, and De Dion-Bouton, they are all British. The motor boat exhibit is far from being so comprehensive as the commercial vehicles, a number of important firms abstaining from exhibiting, owing to the diminished support given by the show committee.

EVIDENTLY CANADIAN TRADE IS COVETED IN ENGLAND.

THE TIRE PRODUCT OF TIRETOWN.

AKRON, O., March 18.—Approximately 62 1-2 per cent. of all of the tires on automobiles exhibited at shows in the large cities this winter was manufactured in Akron. This is the computation secured after an impartial investigation, and proves how important Akron is as the tire center of the country. The figures include the Boston show, held last week. By companies the tire count for all of the shows is as follows: Diamond, 591; Goodrich, 340; G & J, 117; International, 117; Morgan & Wright, 110; Michelin, 97; Continental, 90; Goodyear, 77; Firestone, 54; Ajax, 16; Fisk, 70. The remainder, 21, is scattered among other makes, the total being 1,700. In all 1,788 pleasure cars were shown at the exhibits.

The shows included in the statistics are: Madison Square Garden, New York; Grand Central Palace, New York; Chicago, Buffalo, Cleveland, Washington, Detroit, Philadelphia, San Francisco, Boston, and Minneapolis. The Akron companies in the above list of manufacturers are the Diamond, Goodrich, Goodyear, and Firestone. The last named, of course, manufactures many solid tires.

BOSTON BELIEVES IN MARCH DATES.

Boston, March 16.—The fifth annual show of the Boston Automobile Dealers' Association, the most successful exhibition of its kind ever held in New England, came to an end this evening. From whatever point of view it is considered, this show has been satisfactory. The exhibitors not only have sold many cars, almost every machine in the many spaces being marked with a "Sold" card, but they have got a very large number of prospective customers in line, and have enough follow-up business to keep them hustling until well into the spring.

Those Inter-City Winter Runs.

Besides the demonstrating, the outdoor side of the show attracted much attention on account of the runs from New York. Early in the week four cars were started from that city for Boston. They were an Aerocar, Dragon, Welch, and Wayne. The Dragon, Welch and Wayne were in a sort of competition for a trophy. The Aerocar came through safely, and also the Welch and the Dragon, and finally the Wayne, after much hard luck.

Friday a new record was established between New York and Boston by R. G. Kelsey, driving the Matheson with which the New York-Chicago run was made in January. Kelsey covered the distance from New York to this city in 14 hours 5 minutes elapsed time, his actual running time being 12 hours 45 minutes.

Boston Not Keen on Earlier Dates.

In consequence of the stories that have come from New York this week to the effect that both the A. L. A. M. and the A. C. A.-A. C. M. C. A. shows in that city would be held earlier than usual, there has naturally been some discussion of the question of holding the Boston show a month or more earlier. While some dealers think that a February show would have its advantages, the majority seem to feel that for the retail business March is the best time for the Boston show. If the New York shows are held in the fall it will help out the Boston show, in that when show-time comes the local dealers will be much better prepared than they are now to make deliveries. Very little agency business has been done here, as far as known not a

single new agency being placed in this city during the show, so that all the business is between the dealers and people who are to own cars.

Providence Show This Week.

When the show closed to-night there was a grand hustle to get the cars, which are to be shown in Providence, out of the buildings. Many of the exhibition chassis and cars are to be sent to Rhode Island, while others will be kept in the local salesrooms for a few days or a week, in order to give show visitors a chance to see the machines at their leisure.

MARKET FOR AMERICAN AUTOS IN SPAIN.

Referring to the international automobile exposition to be held next May in Madrid, Consul-General B. H. Ridgely, of Barcelona, sends several prospectuses of the exposition wherein all the conditions are set forth. Copies of the same may be secured from the Bureau of Manufactures. Mr. Ridgely writes:

"This will be an excellent opportunity for American manufacturers to exhibit their products, but it must be repeated that it will not be worth while to show any one-cylinder machine here, as there is a pronounced prejudice against them, and virtually no sale for them. This same prejudice even applies to two-cylinder motors, and as a matter of fact there is little demand in Spain for other than those of four cylinders. Manufacturers who can offer a good, robust, cheap machine of this character, of from 16 to 20 horsepower, at prices ranging from \$1,500 to \$1,800, would probably find a prompt market.

"A good two-cylinder buckboard, provided the motor did not vibrate too strongly, however, would sell in Spain, if it could be offered at a reasonable price, and manufacturers having such machines to export would do well to exhibit them at the Madrid show.

"With the prospectuses referred to, there are various application books which intending exhibitors can fill up and forward to Monsieur le Directeur de l'Exposition de l'automobile, aux soins du Royal Automobile Club d'Espagne, Madrid, Spain. Automobiles intended solely for display at the exposition will be admitted into Spain free of customs duties."

FORMIDABLE PHALANX OF DEMONSTRATING CARS AT BOSTON'S AUTO SHOW, THAT WAS KEPT BUSY LAST WEEK.

A TRULY ARTISTIC BOSTON SHOW STAND, GRAY & DAVIS.

SOUTH AFRICA AS AN AUTOMOBILE MARKET.

Writing from Cape Town, South Africa, Special Consular Agent Raymond F. Crist throws considerable light on the status of South Africa as a market for the American automobile. "American makers have apparently entirely overlooked this fine market," he says, "for inquiry fails to reveal the presence of more than one American agent in all the British South African colonies, though it is an outlet to which the English and Continental makers have found it profitable to devote close attention. American makers appear to be quite content with an intermittent and spasmodic forwarding of beautifully gotten-up catalogues—an absolute waste of printed matter, postage and time. Automobiles in South Africa are not an article of luxury indulged in solely by those desiring pleasure and recreation—they are indispensable to the business success of every man who has relations with the mining industry, many of the most important mines being located fifty miles from Johannesburg, while the Witwatersand "Reef" extends for more than seventy miles, east and west.

The Johannesburg register shows 768 cars now in use, while 200 are reported to be in use in Cape Town. Prices range from \$1,750, averaging about \$2,000, and at a conservative estimate, there are said to be about \$1,000,000 worth of automobiles in Johannesburg every day, while along the length of the "Reef" probably twice that value will be found. The average car is selected for its ability to withstand the hard knocks of the roughest kind of roads, climb steep grades and do the greatest mileage per gallon of gasoline. Although twelve to fifteen miles per gallon is now about the maximum average, upward of fifteen

THE WAYNE CAR IN WORCESTER EN ROUTE TO BOSTON.

miles per gallon is demanded of new cars. Horsepowers range from 6 to 30, but speed is not desired, particularly owing to the nature of the roads. Steam cars are scarce on the Rand, owing to their greater fuel consumption. High clearance is imperative, and while both side-chain and shaft drives are popular, the latter is favored, owing to the great amount of sand, which shortens the life of the chains. Four speeds are required, as with three it has been found that even the lowest is too fast to plough through the long and heavy sandy stretches. Only water-cooled cars are used and they must be equipped with the heaviest tires.

American makers should avail themselves of this exceptionally rich field for the sale of automobiles by sending out salesmen to directly represent their machines. They must be prepared to meet active competitors now in the field from every auto-producing country and whose cars already have a reputation for meeting the difficulties of South African automobiling. A large field is also offered for motorcycles, most of those now seen being of British and German make, the latter predominating. They range in price from \$200 to \$250 and are very largely used. In Durban and Cape Town there are regular automobile and motorcycle clubs. For the year ending June 30, 1906, British South Africa imported \$836,685 worth of motor vehicles.

ALBERT CHAMPION WITH IGNITION SURROUNDINGS.

SZISZ TO DRIVE AN AMERICAN'S RENAULT.

George C. Tyler, the well-known theatrical manager, who left last week for Europe, has just had built for him by Renault Frères, of Paris, the fastest touring car the firm has yet turned out. It is of the standard four-cylinder pattern, of 90 horsepower, and is guaranteed to do 118 miles per hour under the best conditions. Mr. Tyler will be met at Cherbourg by a party of friends, including Booth Tarkington and Harry L. Wilson, the latter the author of "The Spenders." Szisz, the Grand Prix winner, will be at the wheel of the new car. On his arrival in Paris, Mr. Tyler and his party will start East at once, and will go straight through to Constantinople. Some trouble is anticipated in getting the car over the Turkish border, and Mr. Tyler has armed himself with letters from Washington.

On Mr. Tyler's return he intends to visit Bucharest, Budapest, and the Austrian Tyrol; then go to Sicily; through Italy, Germany, and Denmark, and up to Norway, to which, by the way, he introduced the first automobile some few years ago. On his return he will travel through the south of France and will visit the poet and dramatist, Edmond Rostand, at his place at Cambo, at the foot of the Pyrenees. Mr. Tyler last year made 20,000 miles through Europe, and this summer expects to do more.

RUDIMENTS OF VALVE AND IGNITION TIMING

By CHARLES B. HAYWARD.

JUDGING from the frequency with which questions crop up on the subject of valve setting as well as inquiries regarding the reasons therefor, it is quite evident that the importance of the proper timing of the valves of a four-cycle motor is something that is not altogether clear to even that large class of autoists who are far beyond the stage of being merely good drivers. Every now and again there comes to light the old, old story of the man who took his motor apart and found he could not get it together again, but he is greatly in the minority when compared with the case of those who take the motor apart and put it together again—seemingly the same as before, but find that it either refuses to work altogether, or displays such strange symptoms of internal disorder that they are utterly at a loss as to the nature of its ailment. After trying every resource of the experienced driver with no result, the car is sent to a repairer, and there is more than one instance on record where the efforts of the latter have not been any more productive of betterment than those of the owner. To cite but a single instance, there may be mentioned the case of an autoist whose experience extended over several years, during which he had been the owner of no less than five cars, all of which he had taken care of personally, making all ordinary repairs and adjustments, and from all of which he had had good service, the car in question having done several thousand miles with but infrequent minor road troubles before the occasion in question arose. Owing to the peculiar design of the car, it was impossible to dismount the transmission without dismantling the motor—a fact that sheds considerable light on the accessibility of cars of not such extremely ancient vintage, as the origin of the one in question dated back but a few years.

An Instance in Point.

After relating the events that led up to the dismantling of the motor and the fact that continuous trouble followed in the wake of its reassembling, the writer goes on to state that a local repairman and machinist devoted several days' time to it with no result whatever. The case was not an extreme one, as the engine would run in a fairly satisfactory manner when not under load—something that tended to make the trouble appear more puzzling. To sum up the ailment briefly, there was such a considerable loss of power that the car could hardly be run on the high-gear at all, being incapable of doing ten miles an hour on the level, the most noticeable symptom being an escape through both the inlet and exhaust valves that sounded somewhat like backfiring. No amount of investigation of the carbureter or ignition system sufficed to reveal anything amiss, so that an appeal was made to a higher authority for advice in the matter, coupled with the significant statement that no more tinker work was wanted, as it had proved both expensive and unsatisfactory.

The case was not a difficult one to diagnose; everything pointed to improper timing, particularly what was referred to as a sort of backfiring which showed that neither the inlet nor the exhaust was being closed at the proper time, from which it is also quite evident that they were not being opened at the correct moment either, so that the motor was, in fact, running on but a fraction of the charge it was designed to get, and in consequence, but a fraction of the compression required for it to produce its rated output. Under such conditions, it is more of a wonder that it was possible to carry any load at all than that there was so much wrong, as with the modern high-speed motor of the automobile type, such a derangement is usually more than sufficient to prevent the motor from developing any power at all where it does not prevent its running.

Before taking up the subject of valve timing, it may be well to recall the functions of the four-part cycle, particularly as the present is not intended as a technical exposition of the subject,

but rather one for the enlightenment of the novice. Starting with the engine dead, these are suction, compression, combustion and exhaust, following each other in the order named.

Elementary Requirements of Timing.

These four parts of the cycle must take place for every power stroke delivered by the engine, and each one must be complete in itself in order that the motor may deliver its maximum rated power. In other words, each one of these functions constitutes a complete operation in itself, and in consequence, any attempt to make them overlap one another unduly is bound to result in a loss of efficiency. When carried to an extreme, as in the case when the camshaft is improperly placed, it is easy to realize that this sequence may be lost entirely and the motor accordingly refuse to work. For instance, suction cannot take place unless there is a partial vacuum created in the cylinder by the down stroke of the piston; that is, the pressure in the cylinder must be reduced below that of the atmosphere in order for the charge to enter. If the exhaust valve remains open after the opening of the inlet valve, it is evident that these conditions will not be fulfilled. Taking the next operation, that of compression, it is at once apparent that unless the inlet valve be closed very shortly after the completion of the suction stroke, that more or less of the charge will be forced out through it, which will likewise be the case should the exhaust valve be improperly held open at this time. Then again, should the latter begin to open prematurely, or at point very early in the travel of the piston on its power stroke, that much of the useful expansion of the charge will be wasted through the exhaust, as was the case on some of the early motors, which made it next to impossible to muffle them efficiently. Should the inlet valve open too long before the completion of the exhaust stroke, some of the burnt gases are apt to be driven out through the intake pipe, temporarily putting the carbureter out of action and greatly reducing the amount of charge that the cylinder can draw in. Should either of the valves happen to be open at all when ignition occurs, or at any point during the greater part of the power stroke, the pressure will blow some of the burnt gases out through it, as seems to have been the case in the instance referred to where it is stated that something similar to backfiring occurred at both valves all the time.

Factors to be Considered.

Theoretically, then, it is plain that the inlet valve should open at the upper dead center, or beginning of the suction stroke, and close exactly at the other end of the stroke. In the case of the exhaust valve this should be reversed, opening exactly at the lower dead center and closing at the upper, at the same time as the inlet valve opens. But there are factors to be considered in the accomplishment of this which render it necessary to give both of the valves what is termed a "lead," that is, to open them in advance of the points indicated by the theory of the matter. And this is further complicated by mechanical considerations, so that, particularly in the case of very high-speed motors, the operation of opening the valves is something that is begun long before the completion of the respective strokes. The inertia of the valve itself and the opposing pressure of the retaining spring must both be overcome before the valve can begin to leave its seat. It is obvious that it cannot be forced open with a jerk and allowed to reclose with a snap, if smooth action and durability are requisites. This, of course, is a matter that bears more closely upon cam design, but it is evident that it closely affects the timing, as the necessity for opening and closing the valves progressively is important as bearing upon the time element. The easier the curve of the cam, the longer time will be required to lift the valve to the

full open point, and a correspondingly longer period will also be required for it to return to its seat. Naturally, this is also influenced by the extent to which the valve is lifted.

Before the advent of the automobile motor, the average stationary engine was designed to run at speeds varying from 150 to 300 r. p. m., the latter usually being the case with units of less than 12-horsepower and the former in engines over this power. As it was also customary to make the stroke considerably longer than the diameter of the bore, many Continental engines having a stroke of twice the bore, it is apparent that there was considerable leeway permissible in the matter of valve timing. On the other hand, many automobile motors are made "square," that is, the bore and stroke are the same, while in the great majority of instances, the stroke is seldom more than 10 to 15 per cent. greater than the diameter of the bore. In addition to this, few automobile motors are designed to run at much less than 1,000 r. p. m., and most of them at much higher speeds. An engine running at 300 r. p. m. is making 10 strokes per second; an automobile motor running at 1,200 r. p. m. is making 40 strokes per second, or a complete revolution for every .025 second, which means a stroke in every .0125 second. However, as the camshafts only turn half as fast as the crankshaft, they make one turn in every .05 second at 1,200 r. p. m., but when five hundredths of a second must be again divided into

being conducive to silent and easy running, as it eliminates to a great extent the hammering action of the valve in returning to its seat, beside insuring the quick and unobstructed passage of the gases and the elimination of wire-drawing of the fresh charge, which was troublesome in early engines.

But the question of valve diameter, lift and other important essentials connected with this part of the motor, is found to differ in such a great number of instances, and in some cases so radically, that it is only natural that a similar divergence should be found where the matter of timing is concerned, coupled with an equally great variety in cam profiles. It is needless to go further into this aspect of the subject here, as regardless of the great number of differences to be found and the varying standards followed, the underlying principles involved are the same in all cases.

The Necessity of Giving a "Lead."

As already mentioned, theoretically the inlet valve should be fully open for the suction stroke at the beginning of the downward travel of the piston on this stroke. How long before this point is reached the operation should commence, depends upon the speed of the motor, and is restricted by the consideration that the inlet should not actually open before the exhaust valve closes, as the burnt gases may either be blown out through the

FIG. 1.

FIG. 2.

FIG. 3.

FIG. 4.

FIG. 5.

fractional parts in order to cause the opening of the valve to occur at the proper time, it is evident that only a slight divergence one way or the other is necessary to seriously impair the efficiency of the result, if not to prevent the proper functioning of the motor altogether.

Influence of Valve Design.

It is evident that the design of the valve itself must likewise be taken into consideration, but for present purposes it is merely necessary to touch upon it. Modern practice in automobile motor design favors the use of an inlet valve equal to one-fourth the cylinder diameter, and an exhaust of one-third the cylinder diameter, but as it is generally customary to make all the valves the same size to achieve interchangeability in this respect, a compromise between these two limits is usually adopted. With the mushroom type of valve on a seat with walls at an angle of 45 degrees, a lift equivalent to one-fourth of the valve diameter is required to give the theoretical full opening. That these figures are not closely adhered to by many designers is evident from the fact that not a few motors of 5 or 5 1-2-inch bore have valves of 2 or 2 1-4 inches diameter, with a lift of but 1-8 to 3-8 inch, the opening thus being fully 40 per cent. of the cylinder diameter and the lift less than 10 per cent. of the valve diameter, rather than 25 per cent. as above given. There is a tendency on the part of designers of high-speed motors to thus enlarge the valve diameter in order to reduce the lift, this

carbureter or some of the fresh charge from the latter drawn through the cylinder and out the exhaust valve. The closing of the exhaust valve and the opening of the inlet should accordingly be as nearly simultaneous as possible, and in the rough line sketches herewith appended, which are merely designed to furnish an outline of the necessity of giving the valves what is sometimes referred to as a lead, Fig. 1, which is intended to illustrate a motor at the beginning of the suction stroke, shows the former closed and the latter fully open. The piston descends the full length of its travel and at first sight it would appear as if the closing of the inlet valve should coincide with its arrival at the latter, but in addition to the mechanical considerations referred to in connection with the spring and valve, there are similar influences to be taken into account where the charge is concerned. The mixture of gas and air has both inertia and momentum; it does not rush into the cylinder the moment the valve opens, probably half the travel of the piston being required to get it well under way, but by the time the piston is at the bottom of its stroke, the gas has just attained considerable velocity and is pouring into the cylinder in considerable volume. On the other hand, compression of the freshly drawn-in charge does not begin to any extent the moment the piston reverses its travel. In addition to the almost incalculable period of time, speaking of high-speed motors, that it remains stationary at the bottom of the stroke before starting upward, quite an appreciable portion of the first part of the piston's upward travel is

required to create sufficient compression to overcome the velocity of the incoming gases. The point where these two forces exactly balance one another and where holding the valve open any longer would result in driving a part of the charge out again, is that at which the valve should close in order to attain the greatest efficiency. Fig. 2 illustrates approximately the distance beyond the lower dead center for which the inlet valve remains open. It is evident that if this should be caused to occur before or even exactly at the end of the suction stroke, the charge entering would constitute but a fraction of the total cylinder volume; the compression would be poor in consequence and the motor would develop but little power. Where the speed is very high, it is possible to make this point of closing as late as 20 per cent. of the compression stroke, but it is probable that the average allowance will be in the neighborhood of 6 to 12 per cent., or approximately 21 to 43 degrees on the crank circle, the measurement usually being made on the latter, and marked on the periphery of the flywheel.

The influence of advancing the point of ignition is considered subsequently, so that, assuming the compression and firing strokes to have been completed, the proper time for opening and closing the exhaust valve may next be taken up. In Fig. 3 are shown the approximate relative positions of the cams and crank during one part of the intermediate operations, those of compression and ignition, both valves being closed. The charge would be ignited at about the point shown with the spark well advanced

Advancing and Retarding the Ignition.

Whether there is any real necessity for advancing or retarding the point of ignition, is something upon which there is a great diversity of opinion, and the fact that there are well-known motors on the market which show a high degree of efficiency with a fixed point of ignition, merely providing a slight amount of retardation for starting purposes, serves to illustrate that there is sufficient ground for more than one well-founded conviction. It is a subject upon which volumes have been written and a great deal is being added to the discussion constantly. One fact has been pretty well established, and that is that the influences which make for the necessity of shifting the point of ignition are entirely alien to the motor itself, or at any rate, practically so. They are altogether electrical or mechanical reasons, such as magnetic lag of the iron core of the primary winding of the coil, inertia of the trembler, or of the parts of the make-and-break type of ignitor, and the like. The intention in the present article is merely to show what extremely important factors these seemingly trivial things are, and not to go into the technical side of the question as above outlined.

In order to make matters clear to even the novice, the illustrations are arranged to show the relative positions of the controlling lever and the crank, as well as their intermediary, the timer, which governs the point at which ignition shall occur with reference to the travel of the piston. In Fig. 6 is shown what may most aptly be termed a negative point. That is, the crank

FIG. 6.

FIG. 7.

FIG. 8.

and the piston would pass the dead center and travel downward on the power stroke. Before reaching the end of the latter, the exhaust cam would begin to lift the valve, as shown in Fig. 4. The necessity for this will be apparent when it is borne in mind that even at the end of the stroke the pressure in the cylinder would be quite high were it not relieved in this way. The object sought is to reduce this to atmospheric or less before the opening of the inlet valve, as the fresh charge cannot enter the cylinder unless this is the case. With the relative proportions given the standard automobile motor arising from space restrictions of the car—that is, the necessity of making the stroke but little longer than the bore in order to achieve lightness and minimum weight—it is impossible to expand the charge down to anything like atmospheric pressure as is done in stationary engines in which, as already mentioned, it is nothing unusual to make the stroke twice the diameter of the bore. Hence the exhaust valve must begin to open an appreciable distance before the end of the power stroke, varying with the speed at which the motor is designed to run.

This brings the sequence of operations to the last part of the cycle. The exhaust starts to lift from its seat before the crank reaches the lower dead center, as shown in Fig. 4, and for reasons already dwelt upon, it begins to close at a point which represents about an equivalent length on the crank circle before the termination of the upward or exhaust stroke, in order that its final closing may coincide or slightly precede the opening of the inlet valve on the beginning of the next cycle of operations immediately following it.

is on its upper dead center, corresponding to the neutral position of the controlling lever on the sector above the steering wheel. At this point, the ignition is neither advanced nor retarded; the spark would occur at the moment the piston reached the upper limit of its travel. That is, theoretically speaking, the influences already referred to would probably make it necessary to advance the lever quite a few degrees, varying with the speed of the motor to make the ignition occur at this particular point, but for the purposes of the illustration these are not taken into consideration. This position of the lever is that which the driver becomes accustomed to regard as the safest for starting. There is no fear of a back-kick, and at the same time, the ignition is sufficiently advanced for the first explosion to be sufficiently powerful to spin the motor and cause the remaining cylinders to take up their cycle.

In Fig. 7, though the lever is not shown quite to the end of the sector, this represents about the extreme point of advanced ignition, practically 45 degrees on the crankcircle. This is an extreme that is possible with a very high-speed motor, but advancing the ignition to such a point is something that is rarely done and would be more apt to retard the speed of the average motor than otherwise, if not to stop it altogether. The sole object of advancing the point of ignition is to produce the maximum force of the explosion at the beginning of the power stroke. The rate of flame propagation under compression is incredibly high, the maximum initial pressure in the cylinder being attained within a few hundredths of a second after the moment of ignition; nevertheless, it is not so high but that allowance must be

made for the time required. To realize this, it is only necessary to refer back to the figures given with regard to the amount of time required to complete a revolution or a stroke in the case of a motor running at 1,200 r. p. m., which is far from excessive, many motors such as those used in motorcycles running at 2,200 or over, while automobile motors are often designed to run at 1,500 to 1,800, which is not an extreme by any means. In consequence, though it takes but a few hundredths of a second to burn the charge, in that period of time the piston can have traveled an appreciable distance on the downward stroke, thus considerably weakening the effect of the explosion.

In Fig. 3 the extreme reverse is shown, the time of ignition being retarded practically to a point where the exhaust valve is about to open. The proper point for both ignition and valve opening to occur is usually found by taking indicator cards from the engine until positions giving the best results are shown. In a case such as that illustrated by Fig. 8, the card assumes a shape that may be likened to the outline of a club, with the large end where the termination of the expansion in a proper card usually comes, thus showing that ignition and in consequence the rise in pressure did not take place until the piston had almost terminated its stroke, the quick drop showing that the exhaust valve opened immediately afterward. Under such conditions, the motor would develop practically no power and by far the greater portion

of the charge would issue from the exhaust unburned and would burn in the muffler. However, some of the old-time motors with automatically operated inlet valves could not be run at a slow speed in any other way.

To sum up, the standard automobile motor of the present day runs at speeds second only to those employed in small electric motors. It is, technically speaking, a high-speed motor, but its r. p. m. rate is very greatly in excess of anything that has been considered good practice in steam engineering in connection with the reciprocating engine, except in very small units for special purposes. Further, its working necessitates a greater number of operations involving moving parts than any other similar piece of machinery, and the rapidity with which they take place in a motor running at full speed is utterly beyond the human mind to grasp. A speed of 2,000 r. p. m. means that the piston completes 4,000 strokes in the course of 60 seconds; the inlet and exhaust valve each open and close 1,000 times; 1,000 charges are drawn in, compressed, fired and exhausted, all in the space of one minute. Even at half the speed mentioned, the mind fails to conceive the meaning of the time required for each operation; it is difficult if not impossible to realize what a hundredth of a second means. Hence, the necessity of timing the valves to the veriest nicety to produce the maximum efficiency from a given design of motor.

A DEVICE TO EQUALIZE CARBURETER PRESSURES

FROM MOTOR (LONDON).

TO reduce the carbureter to its simplest form by restricting it to a single jet, a single air-inlet and a single method of control is the object of an invention of Messrs. Gillet and Lehman, to which has been given the title of a "controller." Experiment has shown that the incoming column of air can travel at such a speed that sufficient to properly oxygenate the charge can enter at the main inlet of the carbureter as at present constituted without the need

of any other orifices.

Then, the jet being properly proportioned to the engine capacity, it is obvious that a single source of fuel supply is ample. The throttle in the induction pipe virtually rarifies the air and the charge becomes attenuated; theoretically, this attenuation should act on the air and the gasoline alike, but in practice it does not do so, owing to the variation in pressures in the carbureter. At high speed the pressure in the intake falls to approxi-

fast. Theoretically, the action of this inlet should be instantaneously suited to every stroke of the engine—something practically impossible. The Gillet-Lehman device provides properly proportioned communication from the induction pipe to the float chamber, the disturbing variation caused by the throttle being offset by taking one of the balance pipes from either side of the throttle. Thus each stroke of the engine acts instantaneously on the pressure in the float chamber, proportioning the flow of fuel to the draught of the intake.

The device consists of a sort of three-way valve in the shape of a tapered plug; complete it measures but a few inches over all. It is designed to be tapped directly into the top of the float chamber, which must be made airtight with a gasket or washer under the cover, but in the case of the De Dion carbureter shown there was not sufficient room to apply it in this manner, and a small piece of tube B was used. Branching off from the center of the device are the "balance" pipes, both of which are led to the intake C at the jet side of the throttle D at the engine side. The taper plug E, which is hollow down through its center, and has a transverse hole F across its top, has two functions. A screw G controls the opening of F, and is locked by H. The plug E is clamped in position by the cap J. Air entering through F opens communication between the float chamber and the atmosphere. The second function of the plug is to act as an adjusting valve, controlling the opening of the orifices of the pipes C and D. Being cut on an angle, the end is the frustrum of a cone, and, in preparing to adjust the device to an engine, the plug is set so that it closes one-half the opening of each pipe. Then, if turned to the right, it increases the size of the opening of D and decreases that of C; turning to the left opens C and closes D, the relative proportions of the openings of the two pipes thus being varied to suit the engine. L is the sleeve throttle of the De Dion carbureter. A cap is made to screw over the device, completely encasing it, and may be sealed if desired. Assuming the device to be in place on an engine, it is adjusted as follows: F must be open in order to start, as otherwise the fuel could not flow; turning it sufficiently to permit the engine to run normally is the first adjustment, and G can be locked. Should closing F not stop the engine, air is leaking into the float chamber. The plug is turned until the engine misfires at slow speeds and then opened until the engine runs well, turning over slowly. The plug is then locked and the car tried, the adjustment being varied until satisfactory.

SECTIONAL DIAGRAM OF DEVICE.

mately thirteen pounds to the square inch; when entirely closed, the pressure between the throttle and the engine would fall further, probably as near to a vacuum as the tightness of the throttle and the pressure of the valve springs would allow. But in the jet chamber it would still be approximately atmospheric, from which it will be evident that the pressure on either side of the throttle is constantly varying, only being alike when it is wide open and furthest apart when tightly closed. However, the pressure on the fuel in the float chamber has remained constant at atmospheric, from which it is apparent that frequently the supply of fuel must be out of all proportion to the requirements. To overcome this, what is usually known as an auxiliary air-inlet was introduced a few years ago, its purpose being to equalize the pressure on either side of the throttle when the engine is running

EFFECT OF THE CHARACTER OF THE SPARK*

By W. WATSON, D.Sc., F.R.S.

THAT a strong or "fat" spark is better than a weak one, when used to ignite the charge in a motor, appears to be a commonly accepted opinion, while there can be no doubt that in the case of most engines the power developed is considerably greater when the voltage of the ignition battery is well up to its normal value, than when the battery has run down, although the engine continues to fire regularly. Not feeling satisfied as to the cause of the above, and not being able to find the record of any direct experiments, the author has made the measurements recorded below.

FIG. 1.

The engine employed is a double-cylinder one having a bore of 3.5 inches and a stroke of 4 inches. The inlet valve is mechanically operated, and both valves open into a pocket on one side of the cylinder head, as shown in Fig. 1. The sparking plug S screws into the cap used to close the hole over the inlet valve, the spark points being well inside a recess in this cap. All the experiments were made on one cylinder only, the other cylinder working with the trembler coil ordinarily employed with the usual four-volt battery. The speed at which the engine was run varied between 950 and 1,000 revolutions per minute. The primary of the coil used to fire the charge was connected to a commutator on the two-to-one shaft, a battery of ten volts, an adjustable resistance, and an ammeter. The commutator used was either a wipe contact, consisting of a steel wheel and fiber cylinder carrying a brass strip, or a make-and-break igniter.

The reason why a fat spark improves the working of an engine may be either (1) the development of a greater pressure in the cylinder owing to the quicker ignition of the charge, or (2) the more regular firing produced by the timing of the spark being more uniform. Experiments using a trembler coil at once showed that when the current in the primary of the coil is reduced, the

time of firing is delayed, but that on advancing the spark more than usual, the mean pressure during the stroke can be brought back to the value obtained when the usual current is employed. As this indicated that the delay might be caused by the coil, the ordinary wipe contact was replaced by a make-and-break contact, while the trembler coil was replaced by a non-trembler one. As a result the delay, which with the trembler coil took place when the current in the primary was reduced, no longer occurred, this point being illus-

FIG. 2.

trated in Figs. 2 and 3. In each figure the indicator diagram (a) is taken with a strong current in the primary of the coil, and that marked (b) is taken with such a weak current that any further reduction in strength is followed by entire cessation of firing. It will be observed that the timing and the pressure developed are the same in either case, except that in Fig. 3 (b) an explosion has been missed, owing to the spark failing to pass, and the next explosion is much more violent than usual, owing to the scavenging which took place during the idle stroke.

In Fig. 2 the sparking points were .25 mm. apart, and in Fig. 3, .5 mm. Diagrams were taken with the sparking points at .25, .5, and 1.0 mm. apart, but as no difference was obtained, only diagrams for a sparking distance of .5 mm. will be given in most cases.

FIG. 3.

In Fig. 4 is shown the corresponding pair of diagrams when the mixture is very weak, a large excess of air being used. Here again, with the exception of some abnormal strokes following miss-fires, there is no effect produced by reducing the in-

FIG. 4.

FIG. 5.

FIG. 6.

FIG. 7.

FIG. 8.

FIG. 9.

tensity of the spark. The above experiments indicate that it is not the weakness or "fatness" of the spark—at any rate, in this engine—which causes the loss of power that occurs when a trembler coil and a weak current are used. The kind of effect which is obtained with a trembler coil when the current is reduced, the carbureter being adjusted to give the best mixture, which for shortness may be described as a "full mixture," is shown in Fig. 5. In Fig. 6 the irregularity which may occur when a weak mixture is employed is shown, the diagram obtained with the normal current being omitted for clearness. It will be observed that the maximum pressure occurs at all sorts of points of the stroke between the normal and about 4-5 stroke.

The delay which occurs when a weak stroke is used with a trembler coil may be due to sluggishness of the trembler or to the fact that the trembler fails to act, the spark which ignites the charge being produced when the current in the primary of the coil is broken at the wipe contact. The delay which may be produced by lag of the trembler is shown in Fig. 7 for coil A and in Fig. 8 for coil B, and it will be seen that although the delay is appreciable the amount is quite regular, so that all the

spark length in air was in this case 0.3 mm. The mean *I. H. P.* for four cards for each arrangement, taken alternately, was the same within the limits to which the diagrams could be measured; the fact that the speed of the motor was unaltered by the change in spark also indicating that the power developed was the same whether a large or small spark is employed.

From the results of the above measurements it would appear that the trembler, although it undoubtedly is an advantage when starting, is apt to introduce very considerable variations in the point of the stroke at which the charge is fired. Hence, on this account a plain coil with a make-and-break is to be preferred, particularly in the case of multi-cylinder engines having separate coils for each cylinder. The ill effects of the trembler will also be felt when a single coil with a high-tension distributor is used unless care is taken to keep the electromotive force of the battery well above the value required to give the critical current below which the trembler ceases to act. There is one disadvantage in the make-and-break, besides that due to the loss of power of starting on the switch, namely, that with some forms, unless the adjustment is just right, the blade may act as a trem

FIG. 10.

FIG. 11.

FIG. 12.

FIG. 13.

FIG. 14.

FIG. 15.

explosions occur at the same point in the stroke, and so the effect of the delay could, in the case of a single coil, be eliminated by slightly advancing the spark. As the current actuating a trembler coil is gradually reduced there is at first a small lag, such as that shown in Figs. 7 and 8, due to lag in the trembler, and then there is a sudden great increase in the lag. This increase is due to the trembler ceasing to act, so that the spark, in place of occurring shortly after the primary circuit is completed at the commutator, does not take place until the current is interrupted at the contact. When the current is below the critical value, holding the trembler against the upper stop produces no effect on the timing of the spark, showing that the trembler has really ceased to act. The change in current which at the critical value is required to pass from the state when the trembler acts to that in which it fails, is very small, in most cases less than a tenth of an ampere. Figs. 9 and 10 show the diagrams obtained with coils B and C when the current is first just above, and in the second case just below, the critical value.

That the size of the spark has no effect on the power developed was further shown by taking a number of indicator cards in which coil B was used, and the current in the primary was adjusted so that (a) the mean current was 0.6 ampere and the equivalent spark length in air was 5.1 mm., the trembler of the coil acting, and (b) when the current was reduced to 0.3 ampere, the trembler no longer acting, but the delay caused by the fact that the spark is now produced when the commutator breaks, the current being compensated by advancing the spark lever. The equivalent

bler, giving a spark before the cam on the engine shaft finally breaks the circuit, so that pre-ignition is produced. This effect is shown in Fig. 11.

Since the power developed is not improved per se by the use of a "fat" spark, there are many advantages in using a coil which only gives a comparatively small spark, so long as the working of the coil is regular, for such a coil can be designed so that it only consumes a small current. The advantages of a small current are that, in addition to the economy in current, a point of importance where facilities for charging accumulators are not at hand, the wear on the points where the current is interrupted, due to sparking, can be reduced to a vanishing point. Thus, with a trembler coil the trembler, or with a plain coil the points of the make-and-break, need seldom be touched. The author feels confident that by suitably designing the coil and the commutator absolutely regular firing can be produced when the mean current does not exceed a tenth of an ampere.

To show that a fat spark, and hence a large current consumption, does not necessarily imply a good coil, a comparison was made between coils B and C, coil B being that which gave the fattest spark, and C that which gave the thinnest of the three coils tested. The two coils were so arranged that by means of two switches either coil could be used at will, and the current was adjusted in each case to the smallest value at which the coil would give regular firing. The results of the comparison are shown in Figs. 12 and 13. Fig. 12 shows the diagrams obtained with a full mixture, and Fig. 13 those obtained with a weak

mixture. In either figure diagram a is that obtained with coil B, the mean current being .6 ampere, while diagram b is that obtained with coil C, the mean current being .15 ampere. It will be noticed that coil C fires more quickly than coil B, probably owing partly to having a lighter trembler, and partly to the fact that its time constant is smaller.

The two diagrams shown in Figs. 14 and 15 are somewhat outside the scope of the paper, but may be of interest to drivers. They illustrate the advantage, as far as economy is concerned, of advancing the spark more than usual when employing a very weak mixture—that is, when driving with the extra air valve as far open as possible. Fig. 14 is that obtained when the spark is as much advanced as is advisable when using a full mixture, and the *I. H. P.* at 1,000 revolutions is 2.36. In Fig. 15 the spark has been considerably further advanced, so as to allow for the slow burning of a weak mixture, and as a result the *I. H. P.* at 1,000 is 2.76, an increase of nearly 17 per cent. in power, the consumption of fuel remaining the same. Something that will probably come in the nature of a surprise to the average driver.

SOMETHING ABOUT MOTORCYCLES.

Magneto Ignition for Motorcycles.—A strong tendency revealed at the recent European automobile shows was the adoption of magneto ignition for motorcycles. Almost every French and German manufacturer now fits a low tension magneto either as a part of the regular equipment or as an extra. In England the same tendency is observable, though in a rather less degree. The position of the magneto on many of the best European machines, among them Alcyon and Werner, is between the crank case and the front wheel, with drive by bevel gears. On the Werner, for instance, two small bevel wheels are fitted, one on the end of the magneto shaft and the other on the end of the half-time shaft, which crosses the front of the crank chamber. The two small bevels are then connected by means of one large bevel wheel. Another prominent French machine has the magneto placed transversely across the frame, between the lubricating oil and gasoline tanks. Even the very smallest light-weight French motorcycles, machines with a 1 1-4 horsepower engine, have the magneto as a part of their regular equipment for 1907.

Starting a Magneto-Equipped Motorcycle.—Replying to a correspondent who had experienced trouble in starting his motorcycle fitted with Simms-Bosch magneto, *Bicycling World* says that two matters should always be borne in mind. First, the spark plug contacts must be very near together. Secondly, the lever which advances and retards the spark must be in such a position that the break in the electrical current is made when the current reaches its maximum strength. In regard to the first point, it is allowable to have the spark plug points in magneto ignition very close, because that system gives a much better and stronger spark than with batteries; and that the advantages of a short spark gap are that it takes less voltage or potential to jump a short gap and will not short circuit with oil or soot as readily as when there is a long sparking distance. To get the best adjustment, put the rear wheel in a stand so that it may be pedaled. Disconnect the magneto wire which runs to the spark plugs and arrange a circuit so that there will be a spark gap between the high-tension magneto terminal and the frame of the machine equal to 1-8 or 3-16 of an inch. Mount and pedal at a uniform speed, shifting the lever at the same time until the hottest spark is obtained at the gap. Note this position of the timing lever, as it is here the maximum current is obtained, and always put it there in starting. In most machines the proper position is about three-quarters of the way towards highest speed. After the machine is started the spark may be retarded if desired.

BOOKS FOR AUTOMOBILISTS.

Baudry de Saunier's Annual.—Automobilists who have any connection with the trade in France or who are occasionally in need of information on events, men, firms, products, or expressions in the land of the automobile, will find the Annual Baudry de Saunier for 1907 a most valuable volume. The work is a kind of annual automobile encyclopedia of over one thousand pages arranged alphabetically for easy reference, and covers every phase of automobiling and the automobile industry. Should the reader wish to know the meaning of a certain technical expression, the address of some person or firm in the automobile business, particulars of the life of a speed king, the winner of a certain race, the names of tire or other manufacturers, etc., all that is necessary is to turn up the letter in the annual and full information, with drawings where necessary, will be found. The volume is carefully compiled, is brought up to date each year and is fully reliable in its information.

As an Aid to the Understanding of Electricity the automobilist will find "Electric Ignition for Motor Vehicles," by W. Hibbert, A.M.I.E.E. (Whittaker & Co., London) of very great value. The book contains the substance of a series of lectures to automobilists and deals with actual questions asked at these lectures. The elements of electricity are made clear, and the reader is introduced to the practical application of electricity on internal combustion engines. Batteries, commutators and coils, magnetic fields, multi-cylinder engines and synchronous ignition, faults, and magneto methods of ignition are all treated in a clear, concise manner and in such a way that even the novice cannot fail to obtain a good grasp of the subject. The chapter on magneto methods of ignition is thoroughly up-to-date, and deals with the principles involved and their practical application in Eisemann, Simms-Bosch and other well-known magnetos.

A New Question and Answer Book.—Compiling a book on the automobile in the shape of a catechism of stock questions and answers is an old idea borrowed from other fields and that has been made to do yeoman duty in this. A pleasing variation of it is to be found in the little volume just issued by the Gas Engine Publishing Company, Cincinnati, under the title of "Questions and Answers from the Gas Engine." The questions have not been formulated by the editors, but have been asked by progressive readers, and relate to the design, repair and maintenance of all kinds of gas and gasoline engines. They have been answered by recognized authorities, and from the great number which have appeared in the past eight years only those have been retained which are considered to have a permanent value.

Industrial Alcohol; Its Manufacture and Uses.—Under this title Munn & Company have just published a practical treatise on a subject which is at the present time occupying a great deal of public attention. It is written by John K. Brachvogel, M.E., and covers the making of alcohol thoroughly from the raw material to the final rectified product, besides containing numerous chapters on timely matters in connection with its use, such as the importance of tax-free alcohol, methods of denaturing, its utilization for light, heat and power, a statistical review and the Federal law on the subject in full.

A Twentieth Century Hand Book.—Under the title of "Henley's Twentieth Century Book of Recipes, Formulas and Processes," the Norman W. Henley Publishing Company has just issued a handy volume containing information of value to those in almost any industry. It has been compiled by Gardner D. Hiscox, M. E., from the most authoritative sources to be found in each branch, and the information is set forth in such a manner as to make ready reference to everything pertaining to a certain subject available without tedious search.

HOW THE TAXIMETER TELLS ITS TRUTHFUL STORY

In most European capitals the taximeter has entered into the daily life of the people and removed all cause for dispute between passenger and cab driver. In Paris, where the taximeter was first employed, every public vehicle, whether automobile or horse-drawn, is equipped with this trouble-saving apparatus.

FRONT VIEW SHOWING AMOUNT OF FARE.

same liberty as is now enjoyed by Parisians and Londoners.

The accompanying illustrations will familiarize readers with the instrument which, once fitted on either horse or automobile cabs, will inevitably be adopted by every public vehicle in the city. The taximeter here shown is probably the only one at present in New York. It was made specially for service in this city and imported by the De Barres Auto Company, 589 Park avenue, where it is used on a 12-horsepower Delahaye cab of the type commonly employed in Paris and London. Though not plying for service, the cab has been running on New York streets for a few weeks, and its metal box surmounted by an American flag has excited interest and curiosity.

The face of the apparatus has four sets of figures—in the top left hand corner appears either tariff 1, tariff 2, or "Panne," the French word for a breakdown. Below are two openings, showing in dollars and cents the fare to be paid. At the foot of the indicator are registered the extras. The minimum fare is

50 cents, and this sum is always indicated whether the vehicle is in service or not. When a passenger enters the cab the driver lowers his flag and the machine begins its silent but unflinching task of measuring the distance traveled and indicating on the dial the fare to be paid. This is performed in much the same way as speed and distance are measured by a speedometer, a flexible cable connecting from the indicator to the front wheel of a motor-driven vehicle or the rear wheel of a horse cab.

REAR OF TAXIMETER IS A TOTALIZER.

In one important particular the taximeter differs from a speedometer. For instance, should the cab be stopped either for a block in traffic or for the making of a call, a clockwork mechanism within the apparatus advances the figures at regular intervals, making the cost the same for a given time whether the cab be running continuously or intermittently. Experiments have been made with the Delahaye taximeter cab over different routes in New York, each one being accomplished at various rates of speeds, straight running, or intermittently fast and slow, the result being that the fare for a given distance was always the same no matter how that distance had been covered, provided the speed had not fallen below five miles an hour. Four runs were made from the Café Martin to Park avenue and Sixty-third street, one at high speed, another at a moderate speed and a third alternately fast and slow to suit traffic conditions. The average time for this run was then taken and the taximeter set in motion by lowering the flag, the auto not moving, for this period. All four fares were practically the same. It is useless to give figures, for no definite tariff has yet been fixed upon for a New York service.

TAXIMETER CONNECTION TO WHEEL.

All that the passenger has to concern himself about are the figures on the dial. On leaving the vehicle he pays the amount indicated. If more than two people enter the cab the driver turns tariff 2 into view, this registering a minimum 50 cents fare for a shorter distance. Should he be asked to go out of a certain defined district, as, for instance, above One Hundred and Twentieth street, over the Hudson or the East River, the driver will, before starting, indicate the extras to which he is entitled according to a fixed tariff, by operating a push button at the rear of the apparatus. If the machine has a temporary breakdown, the driver turns his tariff square over to "Panne" during which time no change is made on the fare dial, though the amount of time thus lost is indicated on the rear of the apparatus. The repair finished the driver turns his tariff back from Panne to tariffs 1 or 2, as before, and the journey is resumed as if nothing had happened. On the completion of the journey he raises the flag, the extras turn back to zero and the fare dial again registers the minimum of 50 cents. The total distance traveled with the taximeter in operation, the total for extras and time spent making repairs while on a journey are all shown at the rear of the apparatus, and serve as a check between the driver and the company owning the vehicle. A profit-sharing system is generally adopted between driver and owner.

From advice received from London it appears that the metropolitan cabby, who a few weeks ago was denouncing the taximeter as an infernal machine, is now thoroughly converted to its value, for, although under no legal obligation to do so, he is having his vehicle equipped with the instrument. Automobileists declare that this sudden enthusiasm is but a cute move to buy up all the instruments on the market and thus keep the automobile cabs off the streets for a little time longer.

LETTERS INTERESTING AND INSTRUCTIVE

The Gearless Car Again Specifically Considered.

Editor THE AUTOMOBILE:

[639.]—Has there ever been built a real gearless gasoline automobile—one in which there is no change-speed gear nor any equivalent means for varying the rotational ratio between the motor and the driving wheels? If not, how nearly has this ideal been approached in practice, and what is the best engineering opinion as to its ultimate complete realization?

Spokane, Wash.

JOHN C. PERKINS.

Several years ago a prominent French automobile manufacturer built a car propelled by an eight-cylinder engine without gears, except for reversing, but this car never was run enough to demonstrate any really practical qualities. Since then the Napier people, of England, and the Oldsmobile concern, in this country, have achieved some remarkable runs solely on the high gear—which amounts to a substantial equivalent of the gearless ideal, while the Napier people are understood to offer their six-cylinder cars, optionally, without change-speed gear. Of equal, if not of greater significance, as showing the tendency towards gearlessness, is the practice of the Ford company, which makes a six-cylinder touring car in which the drive is through a two-speed planetary gear affording on the low gear only double the engine revolutions that are provided for a given speed on the high. This can mean nothing less than that if the flexibility of present engines could be merely doubled—by no means an impossibility—a car could run gearless quite as well as the Ford runs with its two-speed gear. And it is a fact that the Ford, while expected to run ninety-nine one-hundredths of the time on the high gear, is no more subject to "stalling" than any modern car of similar weight and power. The whole question resolves itself into one of gasoline-engine flexibility, and a very little progress in this direction may bring about the elimination of the speed changes from many cars. How soon this progress is to come is another question, there are many very serious difficulties in the way of it, but more serious difficulties have been overcome. Without going into a more lengthy discussion of the subject than is pertinent to the purpose of this page, it may be said that the matter is one of torque range rather than of speed range. Engines now are made that will *run* as slow as 100 and as fast as 2,500 revolutions a minute, but an engine that will *pull* at all speeds from 150 revolutions to 2,000 revolutions will solve the change-speed-gear problem. Some interesting material on this subject will appear in the course of a series of articles on some trends of modern automobile design.

The Prevention of Carbon Deposits.

Editor THE AUTOMOBILE:

[640.]—Will you kindly tell me under the head of "Letters Interesting and Instructive," the best way to prevent carbon deposits from forming on the cylinder heads and pistons of an automobile motor? I am careful to use the proper mixture of gas, as well as good oil and not too much of it, but the carbon forms just the same.

Baltimore, Md.

SUBSCRIBER.

It is difficult to add anything to such a general statement as you make. By using the correct mixture and the proper quantities of the right sort of lubricating oil, you are doing practically the only things that can be done to prevent the formation of carbon, but you do not throw any light on the extent to which you are troubled by the latter. It is usual to run a motor for an entire season without any undue trouble from this cause, such as pre-ignition, while others, with apparently an equal degree of care, require cleaning much oftener. If you will describe your trouble more in detail it may be easy to suggest a remedy, or probably some other autoist who has had exactly the same experience may be able to come to the rescue and help you out.

More About Wiring Dry Cells for Auto Use.

Editor THE AUTOMOBILE:

[641.]—In your answer to Mr. Stark, of Concord, N. H., in "The Automobile," issued February 21, 1907, you state that with a battery of ten cells connected up in two groups of five cells, he (Mr. Stark) would "get the voltages of five and the amperage of ten cells." Now, I claim that you would get the voltages of five and the amperage of two. Consider ten cells as above, but connected in parallel, that is, positive to positive and negative to negative. You would, of course, have the voltage of one cell and the amperage of ten; that is, the effect would be the same as if we had one cell of ten times the electrode surface, that is, 1-10 of the internal resistance; and on a short circuit, or circuit of low resistance, we would obtain approximately ten times the amperage or quantity of current.

Again, consider the same ten cells arranged in two groups of five each. In this case we have the voltage of five, as five cells have been joined in series, positive to negative, and the quantity of two, for the electrode surface is doubled, that is, the internal resistance is halved, so on a circuit of low resistance the current (amperage) is doubled. To produce an amperage ten times as great as one cell would require ten cells connected in parallel, and to produce a voltage five times as great as that of one cell would require five cells connected in series, so that to produce a voltage of five and amperage of ten would require fifty cells connected in series—parallel ten groups of five each.

Lowell, Mass.

A. R. BLISS.

Upon referring to the letter you mention, though the diagram submitted in connection therewith is no longer available, it is evident that our correspondent was somewhat in error in stating the output of his dry cells, and this error was inadvertently repeated in our answer. It should have read in both cases as "the voltage of five and the amperage of two cells," instead of ten, the makers of the car in question equipping it with twenty cells wired in two series-multiple connected sets, so as to give the voltage of five cells and the amperage of two on either point of the two-way switch. Your statement of the case is quite correct, and we are gratified to note the readiness which our correspondents display in detecting such oversights.

Simplification of Screws and Nuts.

Editor THE AUTOMOBILE:

[642.]—I have a suggestion to make, as from a user to the builders of cars, on which I would like your criticism. Take the average car, even of best quality, and it is a recognized fact that it is in at least some degree subject to breakdown on the road, as often as not involving the repair, replacement, or transference of some bolt or nut. Usually, however, there are not in the tool box bolts and nuts of every size used on the car, since this would involve carrying too many. And the other emergency means of extemporizing a repair—by the removal of one of these small but vital holding elements from an unimportant to an important point—is usually blocked by the same fact that makes carrying a complete set of replacements impracticable—the variety is such that the ones to be had do not fit. Now why would it not be well to reduce this variety and build a car with, say, absolutely no more than three different sizes of bolts and nuts in its whole construction? Would this involve anything more serious than the occasional use of a nut, for instance, considerably large for the stresses to be sustained by it, but not enough so to be really objectionable in point of weight, size, or otherwise?

Kenosha, Wis.

LAWRENCE B. CLAFLIN.

Your suggestion undoubtedly is one of great merit, and if it could be brought into vogue with the manufacturers of the leading cars, there is no doubt but what it would greatly facilitate repairs of all kinds, not only by facilitating "robbing" of one car or part to fix up another, but also by reducing the variety that the average small repair shop would have to stock. In the new standard adopted by the Association of Licensed Automobile Manufacturers for "Hexagon Head Screws" and "Castle and Plain Nuts" there are eleven sizes included—1-4, 5-16, 3-8, 7-16, 1-2, 9-16, 5-8, 11-16, 3-4, 7-8, and 1 inch. To reduce these to the three you suggest there

might be retained only the 3-8, the 11-16, and the 1 inch. This would involve the use of nothing smaller than 3-8, even in cases where the 1-4 or 5-16 might fulfill all strength requirements. Likewise, for anything requiring greater strength than the 3-8 would afford, the 11-16 would have to be used, even if excessively heavy for the duty required of it. And the 1 inch would have to be used arbitrarily in place of the present 3-4 and 7-8 sizes. Probably, everything considered, four sizes would be better than three, but this is a mere minor detail, and it is a fact that there is less occasion than might be imagined for the greater variety. A car with only three—or four—bolt sizes would be almost ideal in this respect, and if the manufacturers have any really sound reason for not building it, now that the suggestion has been made, these columns are open to their opinions, which we all will await with interest.

The Control of the Emergency Brake.

Editor THE AUTOMOBILE:

[643.]—Which is at present the most approved practice, to have emergency-brake levers apply by forward or backward movement? And what are the advantages of each system?

Juarez, Mexico.

ENRICO GOMEZ.

There seems to be somewhat of a preponderance in the case of the most-expensive and presumably best-designed cars in favor of the rearward movement to apply, so that the driver pulls the brake lever towards him to stop the car. Apparently, however, the difference is more a matter of individual preference than of anything else, since there are those who believe strongly in and argue vigorously for each construction. Drawing the brake towards one is claimed to be, and in a manner seems to be, the natural movement, since with it the feet can be braced against the toeboard, or the clutch and foot-brake pedals. On the other hand, if the forward movement is adopted, the brake lever always is in most convenient position to grasp without leaning forward or groping, while it is further claimed that the shock of sudden stopping—the condition for which the emergency brake is supposed to be used—throws the driver forward against the brake lever, and in this way applies it the harder.

A Puzzling Carbureter Ailment.

Editor THE AUTOMOBILE:

[644.]—As a subscriber in your excellent weekly, I appeal to your columns for a bit of advice. I have a 11-4-inch Schebler carbureter on my 20-horsepower, four-cylinder runabout, which has never quite given me entire satisfaction. The engine, when running at slow speeds in a closed throttle and retarded spark, misses fire in a very erratic manner. No particular cylinder is always responsible, but it ekips about with all of them taking their turns at misfiring—the two end ones more often offending. After a vain attempt to eliminate the trouble by carbureter adjustment, I turned my attention to the ignition. I replaced my old wires with new Packard cable throughout; installed a new set of plugs; cleaned the contact points on the timer; carefully inspected the vibrators, assuring myself that they were in perfect condition; had my storage cells recharged, and even tried new batteries, but still with no improvement. Satisfied with the condition of the ignition system, I next took down the carbureter and cleaned it out thoroughly. With the other debris which had lodged at the gasoline inlet, I removed the body of a large fly, and my hopes ran high that I had located the trouble at last.

But still the engine behaved as before. When pulling the car at all speeds from twelve miles per hour to the maximum she acts splendidly, each cylinder hitting as regularly as the clock. In fact, the car is a little wonder on the road, and answers the throttle with remarkable celerity.

But immediately I begin to reduce the speed below twelve—which necessitates closing the throttle entirely and retarding the spark—the misfiring recommences and the machine is often propelled in jerks.

I have spent three months trying to adjust that carbureter properly. If I arrange it so that the engine will hit regularly at the slowest speed, it will not race, for lack of sufficient air; and when the needle valve and air intake are adjusted for high efficiency at the maximum speed (1,400 revolutions), as I now have it, she absolutely will not fire steadily at the other extreme.

This is particularly obnoxious when on a crowded thoroughfare. When it becomes necessary to drive behind a file of ice wagons moving at a snail's pace my engine endeavors to amuse me with a horseless imitation of an amarillo broncho bucking along on one, two, or three "legs."

I would like to have some advice from your valuable paper upon a means of correcting this fault. Is it not possible to secure a richer mixture at slow engine speeds by raising the float level in the carbureter? My idea is that with a higher level a less amount of suction is required to draw a proper amount of gasoline from the nozzle. Do you think this change would help me? I had thought, too, of partially closing the main air intake hole. As you know, this stands open permanently, regardless of the position of the auxiliary poppet valve. It is about 3-8 inch in diameter and admits a lot of air. It is clear to me that the mixture is too weak at slow speed, for when I lay a card over the air intake and gradually slide it over the opening, at a point when it is very nearly closed, the engine begins to fire regularly and perfectly. Can you help me in this case? I assure you that your assistance will be greatly appreciated.

New Haven, Conn.

DICK WILES.

As you state toward the end of your letter, you have located the trouble beyond a doubt by partially closing the main air intake of the carbureter, upon which the engine will run satisfactorily at low speeds. The only thing that remains to be done is to provide a means of supplying a mixture of the character indicated by your experiments. We should not recommend raising the float level considerably to do this, as trouble will doubtless result when running at full speed. Before making any radical changes we should recommend laying your experience before the makers of the carbureter, as this is a rather unusual action for any modern type of compensating carbureter, in view of your statement that no amount of adjustment suffices to correct it. In case no relief is forthcoming, we should suggest fitting a slide or other means of closing the main air intake and inter-connecting this with the throttle, so that when the latter is closed the air supply will also be cut down proportionately and the engine run slowly without missing, as it does when this opening is almost closed with a visiting card, as you relate.

Formulæ for Figuring Rating of Different Types.

Editor THE AUTOMOBILE:

[645.]—As I am a subscriber, I would appreciate it very much if you would give me a reliable formula for figuring horsepower. I notice in Brooke handbook the following is given:

$$\text{H.P. equals } \frac{D^2 \text{ times } S \text{ times } N}{18,000} \text{ for four-cycle motors}$$

and

$$\text{H.P. equals } \frac{D^2 \text{ times } S \text{ times } N}{21,000} \text{ for two-cycle motors}$$

in which D is the diameter of the cylinder bore, S the stroke, and N the number of revolutions. I don't think this can be right, as a two-cycle motor would then have less power than a four-cycle of the same size. Please give me your opinion on this.

Oregon, Ill.

F. R. ZIEGLER.

The formulæ you cite from Brooks are based upon an assumed mean effective pressure, dependent upon the grade and character of fuel used. They are also given by Roberts in his Gas Engine Hand Book, but the denominators there used are 18,000 for the four-cycle and 13,500 for the two-cycle type of engine. In other respects these authorities agree. Roberts gives the following method for determining this denominator, the performance of an engine of the same kind and working on the same quality of fuel being already known. Let X be the unknown denominator; then,

$$X = \frac{D^3 \times L \times R}{B. H. P.}$$

He further states that the above formulæ have been well borne out in practice for the best performance of the average gas engine. We think the old steam engine formula, given in last week's issue of THE AUTOMOBILE in response to letter No. 620, is more satisfactory for both four and two-cycle engines. As to your last question, it is generally conceded that the average two-cycle engine does not actually develop as much as a four-cycle engine of the same dimensions, due

to the imperfect scavenging of the cylinder, the difference being about that indicated by Brooks in his formula. We are aware that this goes counter to the theory of the matter, some makers even claiming that the two-cycle engine will develop twice as much power as a four-cycle of the same dimensions, but this is not borne out.

Information Regarding Front-Driven Cars.

Editor THE AUTOMOBILE:

[646.]—Kindly answer these questions in "The Automobile": (1) Where can I gain any information concerning front-drive cars—Christie's especially? (2) Is it front or back steering? (3) How is the gear-changing performed? (4) What is meant by a two-throw crankshaft? (5) Were there any pictures and description of Christie cars in any former issues of "The Automobile," and will there be any later on?
FRONT DRIVE ADMIRER.

Bayside, N. Y.

(1) In speaking of front-driven cars, we presume you confine yourself to those of the gasoline type. While a number of cars of this kind have been built by investigators, so far as our knowledge goes the Christie is the only one that has been developed to the extent of building more than a single car.

(2) It is front steering and as originally designed (the racing car) was both front and rear-driven.

(3) We believe the change-speed gear is of the sliding type, giving a single speed forward and reverse, and is located inside the crankcase and driven by a large gear fixed to the crankshaft between the pairs of cylinders and engaging a small pinion on a parallel shaft, which is in turn geared to pinions directly attached to the front wheels. This gives the slow speed for starting, the direct drive being by means of clutches at each end of the engine, so that on the high the motor is directly turning the road wheels.

(4) Throw is commonly accepted as a synonym for crank, so that a two-throw crankshaft would be one having two cranks regardless of their placing, and the crankshaft of the standard type of motor would accordingly be termed a four-throw, though its two pairs of cranks only lie in two different planes. In some instances the word appears to be used with reference only to cranks placed at different points on the circumference, so that, taking this meaning as the correct one, the usual four-cylinder crankshaft would be denominated a two-throw crankshaft. We believe current usage, as long established in steam engineering practise, favors the first meaning referred to.

(5) The Christie car has doubtless been described in THE AUTOMOBILE, but it is so long ago that the issue is out of print. The Christie racing car for the Grand Prix will be described in the near future.

Information Wanted Regarding Primary Cells.

Editor THE AUTOMOBILE:

[647.]—I would be pleased to have you tell me through your "Letters Interesting and Instructive": (1) How dry cells are made; that is, what materials are used, and in what proportion, and how. Are there many ways to make these cells? (2) What materials are used in a wet battery? Please give several ways of making these if there is more than one way.

High River, Alta., Canada.

E. H. SCHROEDER.

(1) The composition of the dry cell was explained to some extent under the head of "Sources of Ignition Current," which appeared in the issue of THE AUTOMOBILE of February 21. The positive element is made of sheet zinc forming the containing case; in this is placed a rectangular piece of carbon slightly less in width than the diameter of the container. It rests upon a piece of wood or other insulator, so as not to short-circuit the cell by coming in contact with the zinc. Between the carbon and zinc is packed manganese dioxide, or some other depolarizing material, and a special paste, sawdust or other absorbent. The cell is filled level with the top of the case and a solution of 25 to 30 per cent. sal-ammoniac and water is then poured on the contents until the cell has taken up all the liquid it will hold.

It is then sealed with pitch or similar material, one or two small holes being left for vents. This is substantially the way used in making these cells by the majority of makers, so far as we know, but all the large manufacturers of dry cells have special formulæ and methods of their own, which are trade secrets. We should not advise any amateur to attempt to make dry cells, as they can be had at a fraction of what it would cost, the result of the home process also being doubtful.

(2) It would require a large-sized volume to satisfactorily answer your second question. There are hundreds of types of what you call wet batteries, technically known as primary cells, and it will depend entirely upon what service you wish to use them for. If for ignition, the Fuller bichromate battery will work well on a slow-speed stationary engine, but is not suitable for automobile or boat work, owing to its bulk and weight, as well as its tendency to polarize quickly on closed circuit. Jars measuring about 6 by 8 inches are used, the elements consisting of a large flat plate of carbon and a small cone of zinc, weighing about a pound and a half, and with a connecting wire cast in it. The zinc is placed in a porous earthenware jar about 2 1/2 inches in diameter which is set in the center of the glass jar. A dilute solution of sulphuric acid and water is poured over the zinc and the remainder of the cell outside the porous jar is filled with a solution of bichromate of potash, sulphuric acid and water. This is made by dissolving about half to three-quarters of a pound of bichromate of potash in two quarts of hot water. After it has cooled, one part of sulphuric acid to every ten parts of water is added and the solution again permitted to cool. It is then ready for use. The e.m.f. of this type of cell is about two volts, or slightly over when fresh; it is largely used for telephone service. But, as already stated, it is but one of hundreds of different types. Zinc, carbon and a sal-ammoniac solution in a glass jar is probably the simplest form of open circuit cell, but any of these batteries can be bought much cheaper and much better than they can be made at home.

Formulæ for Calculating Torque.

Editor THE AUTOMOBILE:

[648.]—Will you kindly give me, through your journal, under the heading "Letters Interesting and Instructive," a formula for determining the torque given to a shaft on shaft-driven cars; also the torsional strength of .30 carbon O.H. steel and nickel steel shafts for different lengths?

INQUIRER.

Plainfield, N. J.

Let a horizontal shaft of diameter D be fixed at one end, at the other or free end, at a distance L from the fixed end, let there be fixed a horizontal lever arm with a weight P acting at a distance A from the axis of the shaft, so as to twist it; then Pa = the moment of applied force.

Resisting moment = twisting moment = $\frac{S J}{c}$ in which S = unit shearing resistance, J = the polar moment of inertia of the section with respect to the axis, and c = the distance of the most remote fiber from the axis, in a cross section. For a circle with a diameter d ,

$$J = \frac{\pi d^4}{32}; \quad c = \frac{1}{2}d$$

$$Pa = \frac{S J}{c} = \frac{\pi d^3 S}{16} = \frac{d^3 S}{5.1} = .1963 d^3 S; \quad d = \sqrt[3]{\frac{5.1 Pa}{S}}$$

The torque or twisting resistance of a shaft may then be calculated as follows:

$$T = \frac{\pi}{16} d^3 S = .1963 d^3 S, \quad \text{whence } d = \sqrt[3]{\frac{5.1 T}{S}}$$

In which T = torsional moment in inch-pounds, D = the diameter in inches, and S = the shearing resistance of the material in pounds per square inch. If a constant force P were applied

to the end of the horizontal lever (in the case of a crankshaft, the crankpin) tangentially to its path, the work done per minute would be:

$$P \times L \times \frac{2\pi}{12} \times R = 33,000 \times \text{I.H.P.}$$

In which L=length of the crank in inches, and R=revs. per min., and the mean twisting moment $T = \frac{\text{I. H. P.}}{R} \times 63,025$. Therefore,

$$d = \sqrt[3]{\frac{5.1 T}{S}} = \sqrt[3]{\frac{312,427 \text{ I.H.P.}}{R. S.}}$$

The forgoing formulæ are given by Kent. We cannot answer your last question on the data you give, as the phosphorus content of the steel has a most important bearing upon its strength. You would be more apt to get definite information by inquiring of steel makers of the class of material usually supplied for this purpose, with its specific characteristics.

Two Thousand R. P. M. for Two-Cycle Engine.

Editor THE AUTOMOBILE:

[649.]—I am about to build a four-cylinder two-cycle engine, and would like to have your opinion on these dimensions: Bore, 5 5/8 inch; stroke, 5 1/2 inch; inlet port, 1-2 inch; exhaust port, 3/4 inch, both ports running half way around the cylinder; compression space, 1 5/8 inches, to be fitted with rotary valves in the crank-chamber; connecting rods, 12 1/2 inches. Do you think that this engine will turn up 2,000 r. p. m.? SUBSCRIBER.

Buffalo, N. Y.

From the query at the foot of your letter regarding the speed to which this engine will turn up to, we are led to infer that it is your object in designing it to produce a high-speed motor. In such a case, the inlet and exhaust ports are much too narrow. It is doubtful if a motor of the cylinder dimensions you mention, could be made to turn 1,000 r. p. m. with ports of the size given, and its normal speed would be nearer 500. Of course, it might be raced to up to 2,000 r. p. m. without load, but it could not develop any power at that speed. Making the inlet port 3/4 inch and the exhaust 1 inch would give more suitable proportions and probably it would be found advantageous to increase these dimensions still further, making them 7/8 and 1 1/8 inches respectively, and an increase in the compression, or, in other words, a decrease in the clearance, which we presume you mean by "compression space," would also be desirable. There is no reason why a properly designed two-cycle engine cannot be made to turn up to 2,000 r. p. m.

How to Procure a License as Chauffeur.

Editor THE AUTOMOBILE:

[650.]—Will you please tell me how I can get a license to run a car? I am a driver in New York State, and have worked in a repair shop for one year. F. E. FLYNN.

Fulton, N. Y.

Write to the Secretary of State, Albany, N. Y., for application blanks. Fill out and return with the customary fee and the license will be granted. The formalities required are merely a statement of the applicant's name, address and the names and types of vehicles he is experienced in operating.

Information Wanted on Exhaust Horns.

Editor THE AUTOMOBILE:

[651.]—I wish to make an exhaust-blown horn, but am unable to find any literature that would enlighten me on the size of the reed. It is to be 5-8 inch wide, and between 2 and 3 inches long. Of what gauge spring brass should I make it, and how long, in order to get a deep bass note? E. F. McNUTT.

Youngstown, Ohio.

This is apparently a case where nothing but the "cut and try" process will aid you, unless you can get some maker of this kind of horns to unbosom himself on the subject and give you the result of his experience. Failing the latter, you will have to go ahead and design an experimental horn and see how it works,

correcting the faults that may appear until you are satisfied with the result. We presume the thickness of the spring brass required will depend very largely upon the amount of pressure to be used, not to mention other equally important factors.

Proper Amount of Lift for Valves.

Editor THE AUTOMOBILE:

[652.]—On a 4x4 double opposed auto engine, mechanical exhaust, automatic inlets, how far should the exhaust open, measuring 1 inch or 1 1/4 inches at opening? J. G. BENEDICT.

Coin, Iowa.

With the mushroom type of valve, which is in practically universal use on automobile motors, it is customary to figure on giving the valve an amount of life equivalent to one-fourth of its diameter. This gives the theoretical full opening of the passage closed by the valve; no advantage is to be gained by giving it more lift than this, and less will tend to choke the engine, according to the extent to which the passage is reduced. Hence the proper lift for the exhaust valve of the engine you mention should be one-fourth inch.

A CORRECTION FROM MR. MATLACK.

Editor THE AUTOMOBILE:

[653.]—In your issue of February 21, under the head of "Letters Interesting and Instructive," you printed my letter No. 591, referring to compression and compression space, method of computing. Will you look over my original letter and compare my method with that which appeared in the above issue? I think you will find that I denote the total volume by V (large), and compressed volume by v (small). You also have X equals (Vt plus 460 times 0.002 times 14.7 minus 14.7 equals increase in pressure. But it should be X equals (Vt times 0.002 times 14.7 minus 14.7 as Vt equals 840 plus 460 equals 1300.). And on the twenty-seventh line you have the word "compressure"; it should be "compression." Also, you have

Compression Pressure equals $\frac{v \text{ times } 14.7}{V}$ It is $\frac{V \text{ times } 14.7}{v}$

These corrections agree with my copy.

R. C. MATLACK.

Chicago, Ill.

THE OLD STORY OF PRACTICE VS. THEORY.

Editor THE AUTOMOBILE:

[654.]—No. 607, who signs himself Louis Ruthenberg, causes me to wonder where he got his information as to the practical side of the friction drive. I own a Model 5 Lambert automobile, and from what follows I have demonstrated to my own satisfaction that the Lambert friction drive is all right. This car has carried five grown people and two children up a 25 per cent. grade and six grown people and nine children up a 10 per cent. grade. This same car has plowed through Illinois mud four to six inches deep for eighty miles, averaging nine miles an hour. It has also plowed through Illinois and Iowa sand with the same up to the chains on the sprocket wheels. My first or "greenhorn" paper wheel lasted 1,700 miles in a hilly country. These tests were made with the regular 16-horsepower engine. F. W. STEWART.

Princeton, Ill.

JUST A BIT OF FACETIOUSNESS.

Editor THE AUTOMOBILE:

[655.]—Apropos of some of the inquiries made in your correspondence department, will you please answer the following?

(1) If the inlet pipes from the carburetor were lined with roller or ball bearings, would it facilitate the flow of gas either to the piston chamber or from certain correspondents?

(2) If, at 967 revolutions per minute, a man were seated on the connecting rod wristpin, how soon would he get a headache, and would its relative degree of thermal intensity, calculated in foot-pounds, be greater or less than the one under which the editor must be suffering?

(3) Does the expense of owning an automobile consist chiefly in repairs, guests, or fines? E. P. UNUM.

New York City.

PLEASE GIVE US SOMETHING EASIER.

Editor THE AUTOMOBILE:

[656.]—The picture on page 436 in your issue of March 7 is certainly a "dandy." Will you please explain how a car could run through three or four inches of soft snow, as shown, and not leave a track? And oblige, A SOUTHERNER.

New Orleans, La.

Prospecting for Gold in an Automobile

by A. S. Atkinson.

TONOPAH, THE GOLD MINERS' EL DORADO OF THE NEVADA DESERT, AS IT LOOKS TO-DAY.

PROSPECTING for gold in an automobile is a common experience in Nevada, and the experience is interesting and instructive. The groups of Tonopah and Goldfield mines were originally about 200 miles from a railroad, but the trip on the back of a burro seemed like a thousand. Scores perished in the alkali dust of the desert, but a few persisted. They found gold, and, in spite of the hardships, thousands rushed to the new mining regions. Many of these would have perished had not the automobile come to their rescue. The automobile is the only vehicle which can travel across these alkali deserts without any apparent suffering. Horses and mules drop by the wayside and die like fleas, but the motor-driven vehicle skips along, immune both to dust and sun heat.

When we took our ride across the desert to the now famous mining camps regular auto passenger and freight service was in operation. We could make the trip in a luxurious car for \$20—baggage extra. Everybody made the trip in autos. Even the miner with only a few weeks' funds ahead puts up the amount and travels in state. A good many have made small fortunes in operating autos on this desert trail. One man brought five touring cars here a year ago, and he has been renting them out almost daily at \$100 per day. A chauffeur gets \$10 a day and such perquisites as he can pick up.

Bag of Gold for Breaking the Record.

"Here's mine," explained a young, heavily-goggled driver to me, displaying a sack of gold. "Just took a fellow who struck it rich over to Tonopah and back. Said he'd make it worth my while to hurry. I took him at his word, and we beat the record. When he left me he dropped this in the car."

Judging from its weight, the gold might assay enough to buy a new car. Another young man from the East who came West in his car told me that he had picked up \$10,000 in the past twelve months in carrying passengers and renting out his car. It is not uncommon to pick up crazy-minded gold fiends who will pay almost any price for a machine that will get them there.

When we struck Goldfield there was a subdued excitement in the air. There had been a new strike in the hills by a miner who a few days before had to mortgage his outfit to get food. When we arrived he was worth almost any sum within six figures. He was beset by gamblers, speculators, and miners who wanted to buy him out. Our first glimpse of him was when he rushed out of

one of the saloons, wild-eyed and apparently cornered. Seeing our machine, he rushed toward it and said:

"Say, strangers, how much fur that thing?"

We informed him that we did not care to sell our car, but, not accepting this as final, he continued:

"I want it bad. I want to get out of here fur a breath of fresh air. God, I'm coated an inch thick with alkali dust, and I'll never get rid of it if I don't move out now. I've struck it rich, but I'm goin' to sell out. I won't work the claim."

Then, watching us closely, he said: "I'll give you \$5,000 for that car."

We still demurred, and the man instantly raised his bid:

"Make it \$7,000, and if you won't take that, I'll give you the limit—\$10,000."

Here was a deal made by a gold-crazy, homesick man, but we compromised by offering to take him out of the desert for a nominal sum. We didn't care to sell our car at any price.

Alkali Dust Penetrates Everything.

If you never toured in the Nevada alkali desert you never can appreciate the conditions there. The alkali dust is everywhere. Goggles don't seem to keep it out of the eyes, and within a short time they smart as though pepper had been thrown in them. Then your throat gets dry, thirsty and hard. Breathing is rendered so difficult that an asthmatic is happy in comparison. You drink and drink, but the hard water of the desert simply makes matters worse. It is a veritable inferno for the first few days. Then nature apparently comes to the rescue. Your eyes get more used to the dust and begin to recover. Your throat gets coated with a good layer of dust, and it is then impervious to further trouble. During the season of hardening, however, the average man suffers torment.

Autoists are constantly arriving at the gold fields. Some are there out of curiosity, others are prospectors, newspaper correspondents, gentlemen, adventurers, engineers, mining students, and the driftwood from all parts of the country. The appearance of an automobile costing several thousand dollars is no indication of wealth, nor does a new one excite any comment. There are too many plying back and forth across the desert.

Gasoline at the Point of a Muzzle.

We stopped one day in the middle of the desert and made

preparations to eat our lunch. Suddenly to the right of the trail appeared a black speck, which grew in size until it assumed the appearance of a car flying heavily and asthmatically toward us. The two occupants of the car were trying to attract our attention. When they finally reached our side, the driver jumped down and said:

"Got any spare gasoline 'bout you?"

To our negative reply, he smiled sourly.

"Say, mister, we've got to have a few extra gallons. We've struck a 'lead,' an' we can't abandon it now. We've run short of fuel, and we haven't the time to go back to get more. If you'll let us have a few gallons, say just what you don't need to get you home, we'll pay well for it."

"We haven't much in the reserve tank," I began. Then I stopped and changed my mind. I was looking into the ugly muzzle of a weapon thrust at a dangerous angle toward me. The owner of it said quietly:

"You say, mister, it's worth about \$5 a gallon? All right, me an' my pard will take it. Just fill our tank, and we'll call it an even \$25."

Discretion was the better part of valor. There was no other human being in sight on the lonely trail, and that ugly-looking revolver did not waver. We meekly transferred all the reserve fuel we had on hand. The man chucked a roll of greasy bills in our car and rode off with the remark:

"Sorry, mister, to treat you so. If we strike it we'll set up for you, if we ever meet again."

Think of being held up in the desert in true stage-coach fashion for a few gallons of gasoline!

Did we meet our highwaymen again? Yes, a month later, in a gambling place in Goldfield, someone struck me on the back, and a familiar voice said:

"Glad to meet you again, mister. You did us a pretty good turn that day in the desert. We made the strike, and your gasoline did it. Now just ask for what you want. The establishment hasn't anything aboard that's too good for you. And if they haven't it here we'll send to Denver for it. Speak up."

Our requests were so modest that our erstwhile desert highwaymen appeared disappointed.

Desert Trail Leads Nowhere and Anywhere.

The trail over the desert leads to nowhere and anywhere. It is a winding trail marked out on a desert of alkali dust. In the Winter it is cold and barren, and in Summer so hot that the brain reels. The sun scorches everything, and the hot dust, filled with alkali and arsenic, fairly stifles one. After sundown there is some relief. The stars come out and blink like diamonds. The atmosphere is so clear that the heavens seem miles nearer. Not a cloud or speck of fleece for nights and weeks obscure the heavens. Autoing by starlight is, therefore, the ideal way to travel. After the long, hot day, the night is a relief. A tent of double thickness provided for protection from the hot sun is a godsend. Without it people crossing the desert wilt and shrivel up like leaves. It is a sight to see one of the regular automobile expresses heave in sight and discharge its passengers. There will be some old hardened miners and prospectors who do not appear to mind the terrible ride, but a few newcomers are among the lot. These look worse than seasick passengers on an ocean steamer. They are veritably encased in alkali dust so that it is difficult to move. They have lost all interest in life, and, if conscious, are generally silently cussing themselves for ever leaving civilization.

Before the Automobile Came on the Scene.

Before the automobile came to this region the mining prospector and investor had a hard time of it. The railroads are slow to build new extensions to their main lines to gratify the demands of a small mining camp. There have been too many of such "boom" towns, and the railroads want some assurance that a new settlement is going to be a permanent place of abode. Until this can be demonstrated the miners have to put up with such

methods of travel as they can find. The horse is not adapted to the desert, and the mule can be made to live and do fair work under certain conditions. Freight is transported by heavy wagons drawn by a dozen or more burros, but passengers, infected by the gold fever, can never endure such slow traffic. The auto is the vehicle for them, and so there is a thriving business in these vehicles.

Unlike most mining camps, the new gold fields of Nevada are located at the foot of hills approached by perfectly level stretches of hard sand, across which the automobiles can fairly fly. Here are the greatest speeding stretches in the world. Hard, smooth, and level as a billiard table, and with almost endless vistas, the desert is a perfect place for speeding. It is a treeless and waterless region, but then there are no laws to regulate fast traffic. One can go as fast as his machine will permit, and no one will interfere. It is a scorcher's paradise, but, unfortunately, there is too much monotony in the landscape. Mile after mile is covered, and there is nothing to break the vista of sands. Occasionally one passes a prospector accompanied by two pack burros, or a caravan of heavily loaded wagons drawn by a dozen mules, or possibly some dejected miner who has given up hope and has dropped down by the trail to sleep and die.

The Fierce Ride Across the Burning Sands.

For anyone whose blood runs red, and who knows the exhilaration of fast speeding, the stretches of sand in Nevada must hold a certain amount of fascination. The tragedies of the gold mines, and the fearful heat of the sun and the tormenting pangs of alkali in eyes and throat, are forgotten in the fierce ride across the burning sands. The motor laughs at both heat and dust, and the rhythmic click and chug of the engine form a hymn of praise to man's genius in conquering nature in its worst forms.

There are all classes met in the gold fields, and particularly is this true of Nevada, where the name of Goldfield and Tonopah have served as magic drawing cards. One is surprised at the number of young men fresh from our mining colleges and other universities. They have come to the new regions to get their first hard experience in practical mining. But it is difficult to follow prosaic engineering in such an atmosphere. About half of them change their attitude when they have been here long. One college football player is now driving a passenger automobile, making more money than half those who delve in the sands for gold. Besides his \$10 a day he picks up enough tips and extras to pay for his ordinary expenses. Another operates a stage line consisting of four automobiles between Tonopah and a neighboring mining camp. He is winning a fortune which later he may lose in the gamble for rich strikes. A third has been lucky in renting his machine to rich capitalists who appear on the scene almost daily and demand some means of pleasant transportation. One young man borrowed enough to purchase an automobile, and hied to the gold fields. Within two months he paid back the borrowed money, and to-day he owns in addition to his car two "claims," which may and may not prove valuable.

The autoist, passing through a new country, is always struck by the peculiar differences existing between the people there and from where he came. In the mining camps he can study human nature in the cosmopolitan form. They are all there, and the motor completes the final setting. If it were not for the alkali dust, the intense heat of the sun, and the parched, scorching torment of eyes and throat, it would not be difficult some day to imagine New York not a day's ride away, with all its wealth and fashion and its glitter of things that are not gold.

The annual meeting of the Austrian Automobile Club brought a re-election of Prince Alexander Solens to the presidency, with Major Wolf and Count Szecheny as vice-presidents. The new committee consists of Count Pallacini and Schoenborn and Messieurs Bacher, Buschbeck, Hardy, Dr. von Mayr, Ruziczka, Eger, and Professor Goebel. The club has now a membership list of 891, and is financially in a flourishing condition.

TONOPAH-GOLDFIELD WINTER RUN.

Several months ago Jed Newkirk, an automobile driver of some prominence, came to New York City and selected a car for use in the Nevada gold fields. There comes from him the story of a recent winter trip of two S. & M. Simplex cars embracing several hundred miles of desert and swamp lands, borax beds, and the roadless country between Tonopah, Goldfield, and through Death Valley. The 30-mile run between Tonopah and Goldfield over a road which had had a three-day fall of snow, was covered in less than two hours.

After thawing out at Goldfield for an hour, the party started for Beatty, 71 miles distant. Just before passing through Baton they were obliged to ford a creek and to pass through some remarkably frozen country. At 8 o'clock that evening both cars arrived at Beatty, where the night was spent.

The next morning they started across Ash Meadow, which is 16 miles of swamp. It was not frozen, and, to make things worse, the rain poured in torrents, causing the wheels of the machine to sink in the ooze up to the hubs. After reaching Longstreets' Ranch, where the party partially "dried out," a start was made next morning for Greenwater. On the way it

JED NEWKIRK DRIVING S. & M. SIMPLEX ACROSS THE BEDS OF SALT AND BORAX.

was necessary to ford the Amagoshia river, which has an exceptionally strong current and is about 150 feet wide and three feet deep. In fording the water nearly drowned the motor, short-circuiting the magneto. The distance of 24 miles to Greenwater was covered in three hours.

That afternoon they were joined by a prospector who wanted to show them a claim he had marked out in Death Valley, in the Funeral Range Mountains. While this was only 14 miles distant, it was necessary to travel 90 miles over and around the mountains. There are absolutely no roads in this part of the world, owing to the numerous cloudbursts which make them impracticable. Upon arriving at Death Valley and passing "Scotty's" mine, the Amagoshia river had to be forded once more, and the destination was reached in a little over ten hours.

The party returned to Tonopah by a different route, necessitating the crossing of about six miles of borax beds and a rocky combination of salt and borax brutally rough and as hard as steel. Speaking of this stretch, Mr. Newkirk said: "It has never been crossed by a vehicle before, nothing but burros ever having attempted it. It is 200 feet below sea level and so intensely hot with vapor arising that the eye cannot see a mile in any direction."

The rest of the journey was made through the Furnace Creek Ranch of Smith, of "twenty-mule team borax" fame, over mountains 5,600 feet above sea level, through surfaceless roads that native miners claimed were unnegotiable, and ramming through snow-banks five to six feet deep. The party finally returned to Goldfield and from thence made their way back to Tonopah. Through the snow-drifts it was necessary to use one

car as a snow plow with the second car following in its tracks, pushing the first; then both cars retreating and making a new attack to gain little more headway. This was done for ten hours at a stretch during part of the journey.

MADAME "BOB WALTER" IS DEAD.

France has not had the honor of producing many female automobilists. Indeed, women who drive autos are so much of a rarity that when one is seen it is safe to predict in nine cases out of ten that she is of American origin. Among the few members of the fair sex who have figured in the French automobile world is Mlle. Baptistine Dupré, better known as "Bob Walter," who has just died in Paris after a short illness. Madame Bob Walter is known to most Americans who have visited Paris by reason of her extensive garage in the Avenue de la Grande Armée, and the large business she did in renting touring machines. The firm had a reputation for the part it had played in the sensational runaway matches. A machine was ordered to be at a given address at a stated hour, it took on board a young couple, a few hours later a wedding ceremony was celebrated in Switzerland, Luxembourg, or Belgium, and the next morning the newspapers announced the elopement. Mme. Bob Walter displayed so much discretion in these affairs and was always so successful in her enterprises that she became an essential collaborator in all elopement cases.

The gay Toulousian first appeared before the Paris public as a theatrical artist, but left this profession a few years ago to enter the automobile business. In addition to her garage, renting business, the Napier, Vinot-Deguignand and an American motor boat agency, she played a prominent part in sporting events. At the Gaillon hill climb in 1902 she covered the kilometer in 1:30, one of her competitors being the famous Théry. The following year an automobile demonstration was given in the Bois de Boulogne in honor of the Shah of Persia. Madame Bob Walter was one of those who drove past the royal stand in a racing machine. Instead of rushing by at top speed, as the others had done, she stopped her machine opposite the Royal visitor, much to the annoyance of Baras, who was close in her rear, and who was more concerned over a kilometer record than paying homage to the King of Kings. The lady chauffeur combined with her business and sporting abilities a keen sense of humor and a happy repartee which stood her in good stead on her frequent appearances before the magistrates for exceeding the speed limit.

RACING MEN MUST HAVE SPECIAL LICENSE.

PARIS, March 12.—With the opening of the European racing and competition season, the new regulations of the Automobile Club of France, requiring every driver to have a license, come into operation. Owing to numerous complaints against drivers in touring, endurance and racing events, it was decided last year that no man should be allowed to compete in any event run by the A. C. F., or approved by that body, unless he possessed the competition license. As the club will only recognize those contests in which this condition is imposed, it practically follows that to compete in any race or contest on the Continent of Europe the driver must be licensed by the A. C. F. Obtaining the license is a very simple matter. The applicant should write to the Commission des Concours, at the A. C. F., Paris, stating his demand and enclosing a small photograph of himself mounted on cardboard. The license is pasted on the back of the photograph, and is granted to every applicant giving proof of his ability to handle an automobile. The A. C. F. reserves the right, however, to withdraw the license in the case of accidents caused by the driver, inobservance of racing rules or inattention to the orders of officials. This rule will, of course, apply to Americans taking part in any recognized race or competition in Europe.

TOO MANY RACES IN EUROPE THIS YEAR

THERE is interest and not a little profit to be had by a study of the automobile competitions to be held in Europe this year, for it is quite possible that similar conditions will be met with in this country in the near future. France in particular has made a specialty of organized competitions ever since the days when automobiles ran their faltering course on her broad highways. The policy was a wise one, for it not only encouraged manufacturers to renewed effort and developed better types of machines, but created an interest in the new industry among all classes of citizens. This year there will not be more competitions than usual, but there will be greater variety than ever before. Unfortunately it is not the variety which is the spice of life, but one already the cause of discord and some ill-feeling.

Excepting the Herkomer tour, all the European automobile competitions are speed tests. It is true that they are not all races in the sense of the Vanderbilt Cup or Grand Prix contests, but whether the contestants be 120-horsepower monsters, or small doctors' cars, fulfilling a very varied program, speed is the final standard by which they are all measured. All other schemes for measuring the value of a number of competing units have proved utterly unable to clearly indicate the winner or to present to the public a clear, unmistakable result. There have been innumerable competitions intended to test the all-round qualities of cars, and having for this purpose an elaborate point system. In nearly every case they produce half a dozen "winners" and, as in the case of *Le Matin* tour round France last summer, a prize for everybody.

The present difficulty is how to circumscribe the power of the machines so that the competitors shall start on an equal basis and the most rational type of machine be developed. The A. C. F. first broke away from the old weight limit which for a number of years had been the sole controlling factor in big speed contests in various lands, and substituted a limited fuel supply, as previously experimented by the English in the Tourist Trophy race.

Pleased with their move, the French Club announced a second race on the same basis, but with provision for cars of a moderate power. The limited fuel allowance Grand Prix obtained thirty-four entries—sufficient to give it the mark of success. The second race similar, but with a more limited fuel supply, obtained nine entries—sufficient to brand it a failure. Germany produced the Emperor's Cup race, with a limited cylinder bore, minimum weight and a few specified body dimensions; manu-

facturers showed their approval of the regulations by entering 92 cars, the biggest number obtained in a European race. Italy adopted a limited cylinder bore for its two big races, the Targa Florio and the Brescia circuit. Belgium has the old weight limit for its big race and a limited cylinder area for its Liedekerke Cup, with a provision that at least ten machines identical with the racers shall have been delivered to the public. The Marquis de Dion's foundling, known as the Press Cup, has a limited fuel supply as means of limiting the engine power, a minimum weight, a fifteen hundred miles eliminating tour and a three-hundred miles race as final test.

Discussion is raging fiercely on the various regulations, each one of which has its detractors and its enthusiastic supporters. The Grand Prix generally meets with approval, most manufacturers being of opinion that a fuel allowance of 6.6 gallons per 62.1 miles is preferable to the old 1,000 kilos weight limit. Its only opponents are those who are adverse to racing under any conditions. The second Grand Prix, or Sporting Commission Cup, a speed test on 3.3 gallons of gasoline per 62.1 miles, meets with criticism from every quarter. The opinion is widespread that a weight limit of 2,200 pounds should have been imposed to save the race from featherweight racers. With 6.6 gallons of gasoline an engine of 120 to 130 horsepower will be constructed which must weigh at least 2,200 pounds to stand the strain of a long, fast run. A minimum weight limit is therefore not necessary. With only 3.3 gallons a honeycomb racer weighing not more than 880 pounds, and driven by a high-compression motor of at least 60 horsepower, will be presented. Darracq alone is capable of producing such a light flyer, say the European constructors, and they leave the race severely alone. The German race generally meets with approval, as is shown by its big entry list. Certain critics, however, object that it will by its limited cylinder bore cause the development of engines running at an abnormally high rate. The Liedekerke Cup, the British Tourist Trophy, and the Press Cup of the A. C. F. are all approved in principle, but meet with criticism in their details. It is difficult to find two experts agreed as to the correct body weight and load for a given horsepower. A minimum weight keeps out light freaks, but it does not at all incite the body builder to produce comfortable, light coachwork. As everybody knows, it is weight that kills, and it is time the body builder cut down the enemy as the metal worker has done.

FROM PEKIN TO PARIS BY AUTOMOBILE

PARIS, March 11.—Nineteen cars have been entered for the adventurous auto tour from Pekin to Paris this summer. A few weeks ago *Le Matin*, a Parisian daily journal, made a violent attack on road racing in France and declared with such assurance that the Grand Prix would be annulled that the Automobile Club of France took fright and sought an interview with the Premier. Events proved that the semi-official *Matin* was wrong and a hearty laugh was directed against the journal. Undaunted, the paper attacked the touring contests, declaring that they were all worthless as a test of endurance. The Marquis de Dion took up the defense of the autoists and declared that a modern machine was capable of going anywhere. "Try a run from Paris to Pekin then," said the *Matin*. "Done," said the Marquis, and three De Dion cars were entered forthwith. Since then it has been decided to run the contest westward instead of eastward, and to open the competition to any car without restriction of horsepower, weight or nationality. On June 15 the competitors will be shipped by sea to Pekin, disembarking at Tien-Tsin. The caravan will pass over the Gobi desert, avoiding Moukden and Kharbine, with its anti-auto and anti-Euro-

pean natives. No one knows if there are any roads, but as Cormier, the European Gliddenite, says, the best thing to do is to go and find out. Gasoline stations will be in charge of the Asiatic Petrol Company, of Sumatra, on the Chinese portion of the route, and of Messrs. Nobel on the Russian section. The cars at present entered for the 8,750 miles' run are as follows: Itala, Prince Borghese; De Dion Bouton, three cars of 6, 10 and 15 horsepower; Contal, 8-horsepower voiturette and 6-horsepower tricar; Metallurgique, two machines of 30-horsepower, and one of 40-horsepower; Panhard, 18-horsepower, Baron Duquesne; Porthos (French); Werner tricar; Nistrat (French); Jean Bart (French); Valkyrie (French); Auto Office (French); Sider (French); Passe-Partout (French runabout); C. V. R. (British). There are no formalities, no entrance fees and no prizes. The competitors will be sufficiently rewarded by getting back to Paris, say the organizers. And, it may be added, by the banners and flags, colored placards, big drums and shrill trumpets which the *Matin* will not forget to bring out for its own and their benefit. Americans are invited to enter and show their ability on bum roads and no roads.

SPRING ACTIVITIES IN AUTO CLUB CIRCLES

Annual Dinner of the Wachusett A. C. of Massachusetts.

BOSTON, March 18.—The annual dinner of the Wachusett Automobile Club, held last Wednesday night at the Parker House, brought together not only a substantial number of the club's members, but leading automobilists from the various clubs throughout the State and two national officers of the A. A. A. President W. H. Chase made a versatile toastmaster and the list of speakers included Elliot C. Lee, president of the Massachusetts State Automobile Association; Lewis R. Speare, president of the Bay State Automobile Association and first vice-president of the A. A. A.; F. E. Peabody, president Massachusetts Automobile Club; J. P. Coghlin, president Worcester Automobile Club; G. W. Hills, president Brockton Automobile Club; A. E. Bliss, president Malden Automobile Club; Dr. V. H. Irwin, president Automobile Club of Springfield; Frederick H. Elliott, secretary A. A. A., and A. G. Batchelder, member of the A. A. A. executive committee. Others who spoke included ex-President Putnam of the Wachusett Club, Senator Blodgett and ex-Representative Patton. The Wachusett Club is in flourishing condition, its principal membership being drawn from Fitchburg and Leominster, but the annual function is usually held in Boston at the time of the show in that city.

Philadelphia to Have Monster Orphans' Day.

PHILADELPHIA, March 18.—The advent of springlike weather has brought the local club promoters out of their winter lethargy, and plans are already afoot for a monster Orphans' Day outing, which, with the Philadelphia, Quaker City, and Germantown clubs all co-operating, promises to be one of the largest affairs of the kind ever held in the East. It is proposed to interest the local traction company officials to the extent of having them throw open the many amusements at Willow Grove Park to the little ones, free. If Willow Grove cannot be secured, some one of the other pleasure resorts near the city will be selected. It is expected that upwards of 200 cars can be secured for the run, which would insure a glorious day's outing for at least 1,000 parentless boys and girls.

The Automobile Club of Philadelphia at its meeting last week elected Alfred N. Chandler, Isaac Starr, George B. Linnard, and S. Boyer Davis to the Board of Governors.

Chicago Motor Club Will Hold Three Track Meets.

CHICAGO, ILL., March 18.—Three track meets, to be held on Memorial Day, Fourth of July, and Labor Day, respectively, will be held under the auspices of the Chicago Motor Club this season. This was decided upon at the meeting of the club last week, and Chairman J. W. Hayden of the Racing Committee has applied to the National Racing Board for the dates and official sanction. President F. C. Donald appointed a committee consisting of N. H. Van Sicklen, Secretary George G. Greenburg, F. W. Cornish, O. F. Weber and J. W. Hayden to confer with the Contest Committee of the Chicago Automobile Trade Association for the purpose of mapping out a summer's campaign of reliability runs, hill climbs, etc. N. H. Van Sicklen will represent the club on the A. A. A. Touring Board.

Automobile Club Organized at Stamford, Conn.

STAMFORD, CONN., March 19.—With a charter membership of ten the Stamford Automobile Club has been organized with the following officers: President, Dr. F. Schoir; vice-presidents, Dr. Rice, J. K. Lawrence; secretary, Dr. Dean Foster; treasurer, Dr. J. Howard Smith. Applications to the number of fifty for active membership will be acted upon at the next meeting.

President White, A. C. Buffalo, Appoints Committees.

BUFFALO, N. Y., March 18.—At the recent meeting of the board of directors of the Automobile Club of Buffalo, President Seymour P. White, Vice-President Frank B. Hower, and Secretary Dai H. Lewis were appointed as the three directors from the club to the New York State Automobile Association for the ensuing year. They will attend the meeting of this week in Auburn. President White has appointed the following standing club committees for the present year:

Membership—D. H. Lewis, chairman; J. A. Cramer, E. C. Bull, E. R. Thomas, Charles F. Benzing, N. C. Wilcox, C. B. Penney. Law and Ordinances—H. A. Meldrum, chairman; Louis B. Hart, William H. Hotchkiss, E. H. Butler, W. J. Conners, D. H. Lewis, W. H. Andrews. Grievance—F. B. Hower, chairman; J. W. Gibbs, W. H. Baker, C. A. Criqui, John M. Satterfield, Dr. G. H. McMichael, H. A. Bull. Entertainment—J. B. Eccleston, chairman; Dr. John S. McFarland, D. H. Lewis, S. P. White, W. S. Longnecker, James How, M. E. Taber. Executive—Seymour P. White, D. H. Lewis, John M. Satterfield. Roads—John M. Satterfield, chairman; E. R. Thomas, W. Allen Gardner, George K. Birge, Norman E. Mack, James D. Warren, Ralph Plumb.

Activities of the New York Motor Club.

NEW YORK, March 18.—It is among the probabilities that in the near future the New York Motor Club will have an entire house somewhere in the automobile district. An active campaign of recruiting is to be started at once and a membership close to the thousand mark is expected before the end of the summer. Monthly entertainments will be held.

There was a large attendance at the really excellent smoker given last Friday night at "Reisenweber's," the talent including prominent vaudeville performers. I. W. Fickling, the newly appointed chairman of the entertainment committee, began his tenure of office with gratifying results. Unfortunately the presence at the Boston show of many leading tradesmen interfered with the six vs. four-cylinder argument, which will take place early in April. Guests at the smoker included President Schultz of the Richmond County Automobile Club, who made a felicitous speech; Vice-President Paine, another Staten Islander, and H. A. Bonnell, secretary of the New Jersey Automobile and Motor Club. The next event will be early in April.

Texan Autoists Are Energetic In and About Houston.

HOUSTON, TEX., March 18.—The recent annual meeting of the Houston Automobile Club declared in favor of holding an automobile show in this city next year. In connection with the proposed show, the plan is to hold competitions and valuable prizes will be offered to attract manufacturers and others interested. A special legislative committee, consisting of Thomas J. Anderson, David Daly, Dr. Lossing, John J. Foley and C. L. Bering, was appointed to look after the interests of automobilists in the proposed auto law now before the Texas legislature.

The following officers were elected for the ensuing year: President, Harvey Wilson; vice-president, C. H. Dunbar; secretary, Samuel Bering; treasurer, G. W. Thiel; first captain, John Patrick; second captain, John J. Foley.

Quaker City Club May Have to Select Another Hill.

PHILADELPHIA, March 18.—Although the Quaker City Motor Club has not yet filed with the Park Commissioner a request for a permit to run its Memorial Day hill climb over the City Line road, the notices to that effect published in the papers

Some Popular Ignition Fallacies Shattered. Just who was responsible for the selection of that most incongruous of terms—the word “fat,” to designate the size of an electric spark, will probably always remain a mystery. It is one of those oddities that spring up and become a part of the vernacular of a trade or profession overnight, as it were, and while its aptness from the popular point of view is undisputed, its technical signification is something that yet remains to be satisfactorily elucidated, and probably always will continue in this state. Electrical discharges through air are either in the shape of jagged lines, or are spherical, depending upon the length of the gap and other factors. The former simulates lightning on a diminutive scale, while the latter gives the impression of being more hot and fiery. Its unusual shape doubtless called forth its curious appellation, while the impression mentioned was responsible for the belief that it was the most effective for ignition purposes. If a “fat” spark could be produced at the plug, there was nothing further to be desired in the shape of greater efficiency. Such a spark was believed to be productive of greater power than any other variety.

This is a popular fallacy that has existed ever since the inception of the automobile, and in earlier days it was not confined to the user alone by any means. The coil that could bridge the longest gap or produce the largest arc was considered the best for ignition purposes, as it was thought necessary to have such a spark to fire the charge in the cylinder. To the coil makers is due much of the credit for designing apparatus that relieved the autoist of considerable of the burden of excessive battery maintenance, and recent investigations have demonstrated how

well founded is the contention that a minimum amount of current is equally effective for ignition purposes, as an amperage that proves destructive of contact points. The experiments of W. Watson, D.Sc., F.R.S., whose paper on the subject, read before the Automobile Club of Great Britain and Ireland, is reproduced elsewhere in this issue, are particularly enlightening. He showed conclusively that the length of the spark gap had no influence whatever on the power, while high efficiency was possible with a minimum consumption of current. Modern coils are designed to give satisfactory service on .25 to .75 ampere, but it is Mr. Watson's belief that with properly designed apparatus .1 ampere would be sufficient, which is somewhat of an improvement over the “fat” spark that takes two to four amperes of current.

Standardization Coming as a Natural Sequence.

While the matter of standardization is one that comes in for a spasmodic burst of enthusiastic attention from time to time, usually ending with a suggestion that the parts of all automobiles should immediately be made to conform to a certain standard, the fact that the process is one that is constantly working toward that end without the assistance of any organized effort appears to be overlooked. So far as small parts are concerned, it is extremely desirable, not alone that a certain standard be adopted and adhered to, but that it be one which makes for simplicity to the greatest possible extent. There are entirely too many small nuts and bolts about the average automobile, and, moreover, they are far too diverse in their form and size. The step already taken in this direction is one that will doubtless be productive of good results.

On the other hand, the very thing that the opponents of any general system of standardization most fear seems to be gradually coming about unaided—that close approach to conventional design of both motor and car which it is thought will discount originality and be productive of thousands of cars alike in every respect as so many bricks. There has never been a time in the past when the layman could say with more truth that all automobiles looked alike to him, as is the case at present, yet the premium on originality that is based on sound engineering and economic ideas is as high as ever. What is more, though all cars should reach a point where even the initiated find it difficult to identify them offhand, there is no fear that the time will ever come when it will be possible to pick a car blindfolded, confident of selecting the best of its kind. Given identically the same materials, the same designs and the same class of skilled workmen, the different factories will turn out cars of differing merit, so that it is a waste of time to predict the advent of a day when all cars will actually be alike, regardless of the extent to which standardization be carried, whether deliberately or unconsciously.

Automobiling Now Has Many Organizations.

If an opinion may be based upon the events of the past few months, it is safe to say that within the near future there will be no one, whether manufacturer, dealer, or owner, who cannot lay claim to identification with some body, having as its aim co-operation and the mutual benefit of those directly engaged in its particular branch of effort in the automobile industry. In a pursuit which, though destined to be one of the greatest, had to fight for its existence from the start, the first followers early became aware of the necessity for co-operation, so that automobile builders were represented by an organization almost before they could lay claim to have reached the stage of being an industry. Subsequent events have shown the wisdom of the step, and the unanimity with which the example has been followed by every group having a distinctive interest attests strongly to the benefits to be derived from co-operative effort. The spirit manifested in this universal idea of “getting together” that has been so prominent of late is commendable and should result in the lasting good of all concerned, regardless of the particular branch with which they are affiliated.

MAYOR WHO WANTS MORE SPEED IN PARKS.

PHILADELPHIA, March 18.—The recent meeting of the Fairmount Park Commission considered not a little legislation of interest to automobilists during its two hours' session. First, Mayor Weaver surprised his fellows by filing a vigorous protest against the present maximum speed limit allowed vehicles using the park roads. His honor thought it should be fifteen instead of seven miles an hour. Colonel Snowden thought the present limit is just right—and breaks the law every time he drives his spanking team of bays in the park. The Colonel, who was well aware of the Mayor's bias automobileward, avowed that there are many automobilists who are suffering from what he called the "speed craze." "They are very reckless," he said, "and go spinning along as though everybody else were dirt of the earth." "Well," responded his honor, "I would like to be able to drive through the park without fear of being arrested. Fifteen miles is a perfectly safe limit—for automobiles, at least. The seven-mile limit is violated every day, and the guards sometimes arrest those who exceed it; in the majority of cases they don't. If we only knew when they were feeling charitable we would be safe. But it's dangerous to take a chance with a guard who is liable to enforce the law to the last jot and tittle when his dinner fails to agree with him."

MORGAN AS A GOOD ROADS ADVOCATE.

JACKSONVILLE, FLA., March 18.—W. J. Morgan, well known because of his promotion of the Ormond-Daytona meets and Mount Washington climbs, is a student of good roads building, and while here the other day was interviewed by a *Times-Union* reporter. In the course of the interview he said:

"Every well wisher and believer in the undoubted great future of Florida is fully alive to the tremendous importance that can be attached to the outcome of the endeavor to have the prison labor of the State used for road building and the fate of the bills that will be produced at Tallahassee next April.

"As one who has labored in the interest of the movement North and South, I believe now, as I believed eleven years ago, when I interviewed the governors of the South on the proposition, that prison labor cannot be utilized with better results than it can in providing much needed good roads for every State in the Union."

CONVENTION OF THE AMERICAN ROADMAKERS.

PITTSBURG, PA., March 16.—Automobilists were in evidence at the fourth annual convention of the American Roadmakers' Association, held in this city during the past week. A. R. Par-dington, of the Long Island Motor Parkway, one of the most interesting speakers, was listened to with marked attention. Over a thousand highway commissioners, engineers, and road constructors from various States all over the country, attended the meetings.

One result of the convention was a promise by Highways Commissioner Hunter, of Pennsylvania, to assist by every means in his power the building of the much-sought Philadelphia-Pittsburg highway.

Chairman Robert P. Hooper, of the A. A. A. Good Roads Board, and Augustus Post, a member of the same board, were among those present.

MARYLAND HORSEMAN SUCCUMBS TO AUTO.

BALTIMORE, MD., March 17.—General Alfred E. Booth, for many years one of the most prominent horsemen in Maryland, has sold his entire stable to make way for the automobile. The last team sold was the blue ribbon pair at the Eldridge show last spring and the same two took the honors at the Atlantic City show. General Booth will build in the rear of his residence on Eutaw street one of the most spacious and elaborate garages outside of New York City.

WHAT THE NEW INDIANA LAW REQUIRES.

INDIANAPOLIS, IND., March 19.—Contrary to expectations, the automobile law passed two years ago was changed by the Indiana Legislature which adjourned last week. Those who were closely acquainted with the legislators know that the new law is nothing more nor less than a compromise with the rural constituency of some of the members pledged to make the law more stringent.

The principal change is that of the size of registration numbers, which must now be five inches high, of a half-inch stroke and white on a black background. In approaching dangerous points automobiles must be under control, and must not run at a greater speed than six miles an hour in passing farm houses or animals. Another new feature is that numbers must be carried on both front and rear.

The only other change in the old law is that in the penalties for violation, which formerly was a fine not exceeding \$50 for each offense. The new law provides a fine not exceeding \$50 for the first offense, \$100 or less for second offense and \$200 or less for the third and following offenses.

DELAWARE TO GIVE TEN-DAY PRIVILEGE.

WILMINGTON, DEL., March 18.—The new automobile law is now before Governor Lea for signature. Twelve miles an hour is allowed in cities or towns in which the houses are less than 100 feet apart. Twenty miles is the speed limit in the open country. The registration fee for owners of machines is \$3 and for chauffeurs \$2. Non-residents are allowed to use their machines ten days during the year in Delaware without registration, providing they are registered in their home State.

COLUMBUS, O., TO COLLECT MAIL BY AUTOS.

COLUMBUS, O., March 17.—Permission has been granted Postmaster H. W. Krumm by the postal authorities at Washington to make use of automobiles for collecting mails. The new service will begin July 1. Under the arrangement contemplated, the Government will furnish the machines, and if after a trial the plan proves satisfactory, a full service of autos will be installed for the collection of mail from all the boxes and sub-stations.

FIFTEEN MILES IN ILLINOIS OPEN COUNTRY.

SPRINGFIELD, ILL., March 18.—The automobile bill which has the support of the Illinois State Automobile Association has been passed in the Senate by a vote of 31 to 3. Six miles an hour is called for in business and residence districts and fifteen miles an hour in the open country. Racing on a public highway is prohibited by a \$50 fine.

KULICK TO DRIVE THE FORD CUP CAR.

Henry Ford was a New York visitor this week, and brought news to the effect that his Vanderbilt Cup racer is nearly ready for assembling. It will be driven by Kulick, well known as a Ford pilot in the past. The racer will be of six-cylinder construction and as light as possible.

STILL MORE VANDERBILT CUP ASPIRANTS.

The B. L. M. firm announces that it will construct three racers for competition in the eliminating race for the Vanderbilt Cup contest. Had particulars of the French Grand Prix been sent to this country earlier, the B. L. M. people declare that they would have entered a team of three.

LICENSED SHOW EARLY IN NOVEMBER.

Providing a rearrangement of dates can be effected by the Madison Square Garden Company—which fact is practically assured—it is among the probabilities that the A. L. A. M. show will take place during the first week in November.

THE GRAND PRIX DETAILS.

PARIS, March 12.—Although an official announcement has not been made regarding the manner in which the Grand Prix racers will be started, it is practically certain from the opinions expressed at the meeting of the Sporting Commission yesterday that the Grand Prix racers will be started first, commencing at 6 o'clock and following at one-minute intervals. The Commission Sportive racers will be started at 9 o'clock with four-minute intervals. By this arrangement the first machine to finish the race will be one competing for the Grand Prix. The wood track opposite the grand stand, particulars of which have been given, will be constructed and will be used to start the small racers. It is now practically certain that the wood banked turn proposed near Dieppe will not be built. The members of the Sporting Commission are of opinion that a special banked turn capable of being taken at high speed is not desirable. Knowing that the turn is made for speeding, the drivers will take every risk and will be sure to meet with accidents; whereas, if the turn is left in its natural condition, prudence will be observed. This was proved in last year's Grand Prix, the banked turn near Le Mans being productive of several minor accidents, while the sharp unprepared turns were all taken in safety.

In addition to the tire and gasoline station at the grand stands, there will be an auxiliary tire station at some point about half the distance from the starting point. This station will be confined strictly to tires.

Deliquescent Salts to Prevent Dust.

M. G. Le Roy, professor of chemistry at Rouen, has brought before the Sporting Commission the value of deliquescent salts (chloride of calcium or chloride of magnesium) as a means of rendering the course dustless. Last year the Sarthe circuit cost \$11,000 to tar, and was not satisfactory; as the Dieppe course could be rendered dustless by the use of deliquescent salts for the sum of \$1,000 there is every probability of this process being adopted.

A sum of \$2,000 has been voted by the Commission départementale for the improvement of the road between Dieppe and Londinieres. This stretch, bordered by the local railroad, is at present the weakest point of the course, but so much attention is being given to it that on the day of the race it will be as fast and as safe as any other portion of the circuit. One of the valuable features of the Dieppe district is that the local authorities are all willing to aid in putting the roads in racing condition at their own cost.

King Edward May Attend the Grand Prix.

Rumor declares that a well-known sportsman, a personal friend of the King of England, is endeavoring to obtain the presence of Edward VII at the Grand Prix. No response has yet been given to the invitation, but as details have been studied the belief is expressed that an acceptance will be given. His Majesty would come on his private yacht, sleep on board in Dieppe harbor, travel to the course by automobile, and leave immediately the race was over.

Albert Clement on a 50-horsepower Bayard-Clement, George Heath on a powerful Panhard, Garcet on a Bayard-Clement racer, and Degrais on a Germain have all spent some time on the course during the past week. They all declare themselves satisfied, and predict a high average speed.

Fiat and Itala have officially declared that they will not enter for the Grand Prix. Entries at double fees will be received until April 15 for both the Grand Prix and the Sporting Commission Cup, but it is not expected that any firm will take advantage of the delay.

Mr. Stead, the American racing man of Paris-Madrid fame, has introduced motor taximeters into Monaco in the shape of three-quarter landaulets well upholstered, with electric lighting. The charges are three francs for the first and one franc for each additional kilometer

THAT "INVASION" OF AMERICANS.

After throwing mud at each other for a few days, the editors of the two most important Parisian daily automobile journals appear to have arrived at a common understanding regarding the danger likely to arise from the "invasion" of the American automobiles engaged in the Gold Cup tour. *L'Auto*, the semi-official organ of the Automobile Club of France, now declares that if the tour assumed dangerous proportions it would be obliged to do all in its power to defend the national industry. Judging from some of the remarks, the national industry is a frail creature unfitted for the hard knocks of this wicked world.

The Marquis de Dion, head of the great De Dion-Bouton factory, one of the largest and oldest automobile factories in France, declares in his official capacity of President of the Chambre Syndicale de l'Automobile that it is impossible that a competition should be allowed on the soil of the *patrie* to be organized by foreigners and be reserved entirely for foreign cars. The Marquis fails to tell whether the loss of his American trade has influenced him. One firm, and one only, announces that the X & X machines are not afraid of the American invasion, and that they will match themselves against any competitors.

The French automobile public appears to be unaware of the fact that the invaders consist largely of those peaceful tourists whom they usually receive so heartily and feed so liberally. True, one frivolous Parisian suggested that the Yankee money-bags should be received with all the old world courtesy which was not lost during the Revolution, encouraged to distribute their dollars, to purchase jewelry, works of art, dresses, and everything else that France will barter for money; then, when their American machines are broken down—of course they will all break down—that they should be visited by smooth-tongued selling agents with real automobiles to sell. The hotel proprietor, who only knows that the Yankee brings a big pocket-book with him, thinks this good advice, and would follow it whatever the Parisian thunderers said.

But automobile France has a wider vision and sees in the peaceful travelers the forerunners of that invading host which some day might sweep away the dear national industry.

Georges Dupuy, who is carrying the burden of the work in arranging the Gold Cup tour of the American cars through Europe in July and August, reports nineteen entries up to date, with assurances that at least thirty cars will be obtained for the 4,000-mile journey through eight European countries. Mr. Dupuy is congratulating himself upon the excellent advance advertising which the tour is receiving in France. He is confident that before the cavalcade reaches French soil the makers of that country will realize how futile and uncalled for is any spirit of antagonism which seems to have been aroused through a lack of understanding of the real intent of the tour—that of giving Americans an opportunity of participating in a non-strenuous competition and at the same time seeing Europe in the most advantageous manner.

At a recent meeting of the Commission of Competitions of the A. C. F., called upon to give an opinion concerning the caravan of American automobilists, the Commission expressed itself of the opinion that, "not being international, this test is not a competition, and the results would have none of the guarantees which exist in every competition in which members of automobile clubs have the right to take part."

GERMAN AUTO CLUB IS FLOURISHING.

The annual meeting of the Imperial Automobile Club of Germany proved that the club has prospered exceedingly, and has now a very formidable members' list, consisting of 7 life, 1,106 ordinary, 334 extraordinary, and 34 lady members. The whole of the retiring executive board was re-elected and Count Arco and Dr. Veit newly appointed to the same, which is now made up of the Duke of Ratibor, Prince Hohenlohe, Baron Brandenstein, Count Sierstorff and Herr Goldberger.

RADICAL DEPARTURE IN AUTO MOTOR TESTING

THERE has been installed in the motor testing department of the American Locomotive Automobile Company, at Providence, R. I., makers of the Berliet car, an innovation consisting of a hydraulic brake, which absorbs and accurately measures the brake horsepower developed by the motors. After assembling, the motor is placed on a "jigging" stand and driven by a variable speed electric motor, for the purpose of polishing the bearings,

read pounds, and, by means of a vernier, one-tenth pounds, a sliding weight being moved along the beam by means of a screw and hand wheel, so arranged as not to disturb the balance. The leverage of the beam is so calculated that at 1,000 R.P.M., one pound represents one horsepower, and proportionately, more or less, according to the speed. One-tenth pound read on the vernier, therefore, represents one-tenth horsepower at 1,000 R.P.M., and is proportionate at varying speeds. The pounds pull thus registered is proportionate to the torque of the motor, and by dividing this figure by a constant, the torque at one foot radius can be readily determined.

CLOSE VIEW OF MOTOR ON TESTING BED.

pistons and other wearing parts, and reducing their friction to a point where it is safe to run the motor under its own power. The variable speed electric motor lends itself admirably to this purpose, as it permits beginning the operation at a very low speed and gradually increasing to a speed approximating that of the motor when run under normal conditions. During this period all wearing parts are flooded with oil, and closely watched to guard against excessive and injurious heating.

After the satisfactory termination of this operation the motor is transferred to the test stand proper to be run under its own power. The test stand consists of a heavy cast iron bed plate, supporting the hydraulic brake at one end, and with suitable brackets adaptable to the different size motors at the other. Flexible connections are used for water, gasoline and exhaust pipes to facilitate coupling up and dismantling the motor.

At first the motor is run with no load, and any adjustments necessary in the carbureter or ignition apparatus are made. After being well limbered up, a load is then applied by the brake.

Details of the Hydraulic Brake.

This consists of a casing, or stator, provided at each side with trunnions, supported by segment struts, which in turn rest upon knife edges. The rotor consists of four steel discs 40" in diameter and 1/4" thick, securely keyed to a substantial shaft driven from the motor by a universal jointed shaft and multiple disc clutch. The brake discs revolve in four separate compartments within the casing, but clear the walls in all directions by 3-8", the only metallic contact between the rotor and stator being in the bearings which carry the shaft. The casing is free to revolve through a very small fraction of a degree, its movement being absolutely without friction because of the manner in which it is supported. From the periphery of the casing an arm projects, the end of which is linked to a steel beam supported on knife edges by a pillar in the same manner as the beams of platform scales, the whole forming a compound lever, corrected for balance by an adjustable weight. The scale beam is graduated to

How Readings Are Taken.

When it is desired to take a brake reading, the spring-actuated multiple-disc clutch is permitted to engage gradually, the brake discs then being driven by the motor. Water is admitted to one of the end compartments near the shaft, and its flow regulated by an ordinary globe valve. Centrifugal force carries the water out to the periphery of the disc, creating an enormous pressure, the water serving as a friction medium between the steel disc and walls of the compartment, the result being a tendency of the casing to rotate with the discs in direct proportion to the friction, and hence to the torque. Whatever friction results from the rotation of the shaft in the bearings of the brake casing, has a tendency to revolve it in the same direction; therefore, the entire power developed by the motor is accounted for by the weighing apparatus, which counteracts the tendency of the casing to rotate. It will be seen from this that no losses occur in the transmission of power from the motor to the brake, and readings are accurate to within a small fraction of 1 per cent.

If one disc or compartment is not capable of absorbing the total power of the motor, the compartment at the other end of the casing can be brought into service, and the water in these compartments may be transferred to the inner compartments by means of by-pass valves, thus bringing all four discs into use and absorbing the maximum power of which the brake is capable. By varying the quantity of water in the compartments a very flexible control is obtained. This is done by regulation of the

COMPLETE APPARATUS READY TO OPERATE.

inlet and outlet, or drain valves. The mechanical energy of the motor is converted into heat inside the brake, and is carried off by the water, the temperature of which is usually kept below 150 degrees F. The larger motors developing greater horsepower, and, in proportion, a greater amount of heat, require that a greater volume of water pass through the brake in a given time.

As the only available water supply at the American Locomotive Automobile Company's plant is from the city mains, means are

VIEW OF THE SECTIONAL RADIATOR AND BLOWER.

provided for cooling the brake water, as well as the jacket water from the motor cylinders, and using it over and over again. It is returned by pumps through a series of radiators, cooled by air from an electrically driven fan, to storage tanks, from which it runs by gravity again to the motors and brakes. The radiator tubes are arranged in parallel and controlled by a series of valves, in a such a way that any number of sections can be made inoperative, thus providing a means for maintaining a constant temperature of water supplied to the brakes and cylinder jackets, regardless of varying atmospheric conditions.

Advantages of the Hydraulic Brake.

Aside from its flexibility, one of the chief merits of the hydraulic brake is its constancy, and therefore its readings may be relied upon with absolute certainty. A tachometer belted from a pulley on the motor cam shaft gives the speed of the motor at all times, and during the test readings are taken at regular intervals of the pounds pull and speed indicated, and a record of the performance of each motor kept. These records are filed away for reference and may be seen by purchasers. The conditions to which motors are subjected when on test are as nearly as possible analogous to those met with in actual service, which are desirable from many points of view.

A spacious room is specially equipped to facilitate the work of motor testing. A traveling crane lifts the motors from the shop trucks to the stands and vice versa, and transfers them from one part of the room to another. The exhaust is led into

an underground pipe, with an outlet at some distance from the building. The gasoline tank is buried at some distance from the building, and gasoline is supplied to the test room in the safest manner. A small sheet iron house erected over the main supply tank contains a small tank holding about three gallons, and placed somewhat higher than the carbureters of the motors being tested, connection being through underground pipes. Gasoline is supplied to the small tank by a centrifugal pump at the bottom of the main tank, driven by an electric motor, controlled from the test room.

In case of fire the fuse in the motor circuit would burn out, only permitting the fuel in the small tank to flow into the room, should the carbureter connections be severed.

HARTFORD COMPANY MAKES MANY CHANGES.

In addition to the resignation of Secretary Gilson, as recorded last week, many other changes in the personnel of the officers of the Hartford Rubber Works Company resulted from the last meeting of the board of directors. Thomas Midgley resigned as president to devote himself entirely to the interests of the Midgley Manufacturing Company, of Columbus, O., of which he is the head. His successor is J. D. Anderson, who only resigned the vice-presidency of the Hartford company several months ago to accept the presidency of the G & J Tire Company, Indianapolis. V. B. Lang, who succeeded him at the time, has been re-elected vice-president and also appointed general manager, while H. Plow was elected treasurer, and E. R. Benson, formerly manager of the company's Boston branch, was elected secretary.

WHO INVENTED THE MOTOR SCOOTER?

A new invention is never produced without its originality being contested. Nathaniel Roe presented a motor scooter a few weeks ago which seemed to have solid claims to originality. It appears now that Roe was not the first to travel over the ice in a motor-driven boat. During the winter of 1904-5 Chas. G. Ketcham, of Eastport, L. I., fitted an ordinary scow with a two-cycle, 3-horsepower gasoline motor, connected direct by a belt to a large spiked wheel mounted forward of the motor and adapted to engage the ice through a slot in the floor of the boat. The motor scow was steered with a sharpened steel rudder blade on the end of a long sweep. Ketcham's craft seems to have embodied the same ideas as were presented recently by Roe, but in a rough and unfinished manner.

CROSS SECTION AND LONGITUDINAL ELEVATION OF THE AMERICAN LOCOMOTIVE COMPANY'S MOTOR TESTING PLANT.

H. I. CASHMAN ASSISTING FLOODED FOLK IN ALLEGHENY, PA., WITH HIS WHITE STEAMER. STREETS NEAR RIVERS WERE OVERFLOWED.

AUTOS AGAIN PROVE INVALUABLE.

If there were ever any motorphobes in the downtown district of the city of Allegheny, Pa., they probably revised their ideas after the great flood of last week. Never were means of swift and sure transportation more needed than when the rivers commenced to overflow their banks and to inundate a part of the residential district. Although warnings there had been in plenty that a flood was imminent, it was not until the water commenced to course through the streets that people thought of abandoning their homes and seeking shelter on higher ground. Then they found that the means of escape at hand were hopelessly insufficient. Those who had obtained possession of rowboats were charging \$5 a head to carry people to places of safety. Empty boxes, planks and all kinds of household furniture were pressed into service as rafts. In many instances these frail craft were swept out into the river, with the result that over twenty lives were lost in this way in the vicinity of Pittsburg alone.

The flood of the three rivers reached the height of 36.2 feet, more than a foot higher than ever recorded before. Automobiles were about the only vehicles to be seen in dozens of submerged streets, and they performed their service so well that it has been suggested that the Pittsburg police department keep an exact record of the location of every big garage in the city, so that in flood times they might call on the managers for autos in extreme cases. These owners and managers, by the way, showed a measure of public spirit last week that has never been equaled in Greater Pittsburg. In their own way, and unaided, they organized an automobile service that gave direct and timely aid to hundreds of business men and women.

H. I. Cashman, with a White steamer, was one of the earliest arrivals on the scene in Allegheny, having crossed the bridge merely out of curiosity. Finding need of his services, he immediately went to work, and from along the water front carried many loads of people to places of safety. The Banker Brothers had a car carrying twelve persons running back and forth, and excellent service was provided by the Winton and Darracq branches, and the Colonial and others were equally helpful.

THAT BOSTON TO NEW YORK MOTORWAY.

Boston, March 19.—Many prominent automobilists attended to-day's hearing before the Roads and Bridges Committee of the Legislature in reference to the proposed motorway from New York to Boston. The estimated cost is \$70,000 per mile, total length 172 miles, and cost of construction about \$15,000,000.

RECENT RAMBLER NON-STOP RUN.

Van Evra B. Martin's 2,000 miles non-stop run on a Rambler machine was privately undertaken to prove that a stock machine was capable of a 1,000-mile trip without stopping the motor and without any particular preparation. The road conditions were the worst possible for such a trip. The engine was cranked by Sherburne M. Becker, mayor of Milwaukee, and the car was driven by Mr. Martin himself. The total time between the starting of the motor and the handing over of the engineers for a thorough examination of the parts was 168 1-2 hours, of which time the car had been on the road approximately 153 hours. Total mileage covered was 2,281, and the total distance covered up to the time of stopping the motor was 2,002 1-2 miles. The running time of the motor was 140 hours and 36 minutes.

For the two thousand miles run 137 1-2 gallons of gasoline were consumed, thus the mileage was 14 1-2 miles per gallon. The oil consumption was 19 1-2 quarts. Figuring the gasoline at 18 cents per gallon, the present retail price in Milwaukee, and the lubricating oil at 50 cents, the fuel cost aggregated \$24.75.

Hartford-Dunlop tires, with Midgley treads, were used and held up particularly well in view of the road conditions.

On the completion of the trip the car was entirely dismantled and publicly examined by Vigil Oldberg, M.E., of the Armour Institute of Technology, and Edward B. Waite, head of the instruction department of the American School of Correspondence. It was found that the entire replacement of parts showing wear would cost, including time, but \$7.50.

HOW THE ROADS WERE ON RAMBLER NON-STOP RUN.

GUSTAVE CHEDRU JOINS THOMAS COMPANY.

A valuable addition has been made to the engineering department of the E. R. Thomas Company, of Buffalo, by the appointment of Gustave Chedru as its head designer. Some intimation of the personnel of this corps was given when it became known that Gustave Caillois, late of the Brasier factory, was at the head of the

GUSTAVE CHEDRU.

Thomas racing team on the Vanderbilt cup course. The other members of the department were not, however, made known. Prior to joining the Thomas interests M. Chedru was technical manager and consulting engineer with the Société des Automobiles Théry. He began his designing career eighteen years ago with the Continental Edison Company, later becoming designer for the Compagnie Electrique Théry. During his fourteen years connection with gasoline engines he has been designer for the De Dion-Bouton firm, chief engineer with the Richard-Brasier factory, and superintendent with the Bayard-Clément company. Mr. Chedru is the designer of the Brasier racing machines which won the Gordon Bennett Cup two years.

HARRISON WAGON COMPANY REORGANIZED.

GRAND RAPIDS, MICH., March 18.—The Harrison Wagon Company, manufacturer of automobiles, and the Harrison Land Company, have been reorganized with the following acting as directors in both companies: J. R. Wylie, C. H. Hollister, Mark Norris, Maurice Shanahan, and H. W. Marsh. These directors elected the following officers for the wagon company: James R. Wylie, president; Clay H. Hollister, vice-president; Mark Norris, secretary and treasurer. This action was taken to give the entire control of the Harrison properties to the creditors. The automobile department of the factory will be continued.

RUNNING DAY AND NIGHT FOR TWO YEARS.

CHICAGO, ILL., March 18.—W. Hildreth, manager of the Holman Automobile Company, states that recently 15 cars were shipped in a single day and 35 cars was the total for the week. The factory has been in operation day and night for the past two years, and there appears to be no signs of a let-up, in view of the many orders that await delivery.

"BOB" ALEXANDER TESTING POPE-HARTFORD.

In all kinds of weather Pope-Hartford cars are given severe trials in the neighborhood of the factory. "Road King" Alexander is doing Newington mountain near Hartford, Conn.

DETROIT PRODUCES A NOVEL COMBINATION

DETROIT, MICH., March 18.—Rodolphus Fuller, a resident engineer of this city, has just completed the first one of a new type of motor trucks designed particularly for heavy haulage. As will be plain at a glance from the picture of the new machine, it departs from the conventional vehicle of this class in a number of respects. It is a combination gasoline-electric wagon upon which Mr. Fuller has received patents. The power plant consists of a four-cylinder, 40-horsepower gasoline engine, direct-connected to a multipolar direct-current generator of the standard type, and is located in a sort of housing the top of which does duty as the driver's seat.

The actual driving equipment consists of two electric motors, one of each of which is carried on the front and rear axles in connection with a differential. The controller is somewhat similar to the type used on street cars and gives the different speeds by varying the amount of current passing through the field windings of the generator, any speed up to a maximum of six miles an hour being available either forward or reverse. The control may be further varied by applying the power to either the front or rear motor separately or to both simul-

NEW GASOLINE-ELECTRIC TRUCK FOR HEAVY WORK.

aneously. A turntable type of front truck is used in preference to the usual knuckle style of guiding the vehicle in order to obtain a sharper turn, a turning radius of little more than its own length being claimed for this vehicle. Ball bearings are used to reduce friction on the turntable, while an indicating pointer shows the driver exactly the direction the front wheels are heading at any time. The machine runs on steel-tired wheels, and to refute the criticism that has arisen on this point, it is said that the inventor has demonstrated that the tires have sufficient traction by running the car through deep mud. The carrying capacity of the truck is seven tons, and its weight 3,850 pounds, or just 55 per cent of its effective load, allowing an unusually high efficiency. A company is being organized to manufacture the new trucks, which will be placed on the market at \$5,000.

LONG ISLAND MOTOR TRADE ASSOCIATION.

Following a preliminary meeting of a number of prominent agents and dealers in Brooklyn a fortnight ago with a view to co-operation, a meeting was held at the Imperial on the evening of March 14, and as a result the Long Island Motor Trade Association was organized. E. H. Barnum, Ormond Company, was elected president; L. H. Allen, I. S. Remsen Mfg. Co., vice-president; B. D. Underhill, Brooklyn Motor Car Supply Company, treasurer, and D. D. Martin, New York Broadway Tire Company, secretary. Fifty dealers were present, and numerous others wrote signifying their intention of joining the association, something of a surprise being occasioned by the election of the Standard Oil Company to membership.

BRIEF ITEMS OF NEWS AND TRADE MISCELLANY

The Mitchell Auto Company has been organized to handle the Glide line of cars in St. Joseph, Mo., and vicinity, and will keep a full line of Glide machines of the different models in stock.

The placing of vanadium steel on a commercial basis enables American automobile makers to produce machines that are unsurpassed in any particular by cars made in Europe, declares Henry Ford.

The National Electrical Supply Co., of Washington, D. C., wholesale and retail dealers in automobile tires and accessories, has been authorized by the state corporation commission of Virginia to increase its capital stock from \$100,000 to \$200,000.

The Alamo Engine Works, of Hillsdale, Mich., is engaged in erecting an additional machine shop, 127 x 40 feet. The building will form a unit of the group plan which the factory will require for its business. The company's business is rapidly increasing.

Capitalists are at present interested in a proposition from C. H. Brooks, of Detroit, for the establishment of an automobile factory at Port Huron, Mich. The new factory would manufacture the "Brooks" car, a new machine which will be placed upon the market this year.

Having decided to purchase automobiles for the use of its inspectors, the Bureau of Highways of New York City decided upon the Model E four-cylinder Mitchell as the most satisfactory car for their requirements. The purchase was made through the Mitchell Motor Company, of New York, at 1787 Broadway.

Charles Clifton, treasurer of the George N. Pierce Company, of Buffalo, believes the six-cylinder car to be the best thing for high power cars. His view is that the six-cylinder engine has proved its superiority to the satisfaction of engineers, and that users will adopt this type as fast as they become acquainted with its real merits.

After running the round of all the big shows the Lozier 40-horsepower motor inclosed and operated in a glass case, is about to be shipped to the Lozier headquarters at Fifty-fifth street and Broadway. This motor has sections cut from the cylinders, valve chambers, etc., enabling the observer to see the inner working and operation of the engine.

D. L. McDonald, a Texas real estate agent, finds his Winton invaluable in making land sales. "If it were not for this car," he says, "I simply could not do business, for our land is so far away from railroads and trolleys, and I have yet to find a team of horses that could handle a load of seven passengers at the speed and over the grass-grown country that the car can easily negotiate."

Owing to a typographical error in the Warner Instrument Company advertisement in the March 7 issue of THE AUTOMOBILE, what was really a very creditable showing for that well-known instrument in the Glidden tour was made to appear of only passing interest. The original copy read that thirty eight instead of eight of the sixty-two Glidden tourists had their cars equipped with Warner Auto-Meters.

One of the most important orders received by the Hartford Suspension Com-

pany came last week from the Olds Motor Works, which sent in a preliminary order for 100 sets of Truffault-Hartford shock absorbers to be used as equipment on their high-speed gentleman's roadster. This adds another big manufacturer to the sixteen already in line who consider the shock absorber a necessary addition to their cars.

One of the most uniquely finished automobiles turned out has just been delivered by the E. R. Thomas Motor Company, of Buffalo, to O. P. Letchworth of that city. The car is a silver plated Thomas Flyer, all of the exposed brass parts on the car having been coated with silver, giving it a rather dazzling appearance. The use of silver by Mr. Letchworth is not a fad, but has been adopted by him owing to the fact that he believes it can be kept clean much easier than brass.

Some misapprehension has arisen regarding a notice made in THE AUTOMOBILE of March 7, dealing with the occupancy by the Buick Company of a portion of the Winton branch at Chicago. Some time ago the Buick Company leased for two months a section of the second floor of the Winton premises, this section being separated by a brick wall. As a matter of fact the Winton Company uses the entire first, second and third floors and basement of the Winton branch at Chicago.

The first 1908 American Mercedes built in the new factory of the Daimler Manufacturing Company, of Long Island City, has been sold to the Garden City Company, of Garden City, L. I. This will be the first 1908 German Mercedes model, as the American Mercedes is made from the latest blue prints furnished from the parent factory in Germany. The Garden City Company is practically the Stewart estate, and the new garage this corporation intends constructing on its land this spring will be one of the finest in America.

Mrs. William K. Vanderbilt, Jr., has recently purchased one of the new White Steamers. This car will be the third successive model of this make which she has owned. Mrs. Vanderbilt is at present in Europe and the order for the car was given to the White garage in New York by her sister, Mrs. Herman Oelrichs. Mrs. Vanderbilt has always shown a marked preference for the White, and this is the only make which she essays to drive herself. She is frequently seen scurrying along the Long Island highways.

The plant of the Tweedale Foundry and Machine shop, at Constantine, Mich., has been taken over by the Constantine Manufacturing Company, organized by Charles Cohn, Constantine; C. E. Fousel, Centerville; Luther Sevison, Port Huron, and D. L. Chipman, Peoria, Ill. The new company will manufacture the Sevison sparker for gas engines. It is attached to the flywheel and is said to be able to furnish the necessary spark for an indefinite time. Plans are also under consideration by the company for the manufacture of several other electric articles.

An employment bureau has been opened by the American Motor Car Manufacturers' Association which it is expected will prove advantageous to its members. Good men are hard to get and it is felt that a central bureau where applications could be received either for men or for positions would work

out well. This move is the result of numerous applications having been received for sales managers, factory superintendents, salesmen and demonstrators. All applications for positions are placed in the employment department, and are held confidential. They should be addressed to Alfred Reeves, general manager, 29 West Forty-second street, New York.

An excellent method of educating owners of Maxwell automobiles on the construction and care of their machines is being adopted by the Maxwell company. A textbook has been compiled consisting of a series of eight lectures arranged in sequence. The first lecture deals with everything in the most elementary manner and makes the subject clear to even the most ignorant. Later lectures deal with the technical features of the automobile, the text being made clear by numerous diagrams. The last lecture discusses many points of value on the cost of upkeep of a Maxwell car. The book has been prepared under the care of A. A. Grant, author of "The Making of an Automobillist."

An enthusiastic autoist who has his Columbia car provided with three styles of bodies, writes: "Before purchasing my car I had little idea of the wide variety of service that can be obtained by going to the expense of extra bodies. During the early spring I fit the car with a touring body which seats the whole family. In the summer, when most of the family is at the shore, I substitute a runabout type. My son and I drive to work every morning, a distance of ten miles. On Saturdays we drive to the shore, fifty miles away, and remain there over Sunday, when other members of the family make use of the car. In the early fall a touring body is again fitted to the chassis and is provided with a cape top having side and front curtains, affording ample protection from the elements. In the winter a limousine body is fitted which is especially desirable for the trip to and from the office and for the ladies of the family for shopping and calling. Thus my car is made to serve the purposes of a good stable of horses. I have found the investment a good one."

NEW AGENCIES ESTABLISHED.

John T. Fisher has opened an agency in Chicago for the Mercedes Import Company, at 319 Michigan avenue.

The Southern Automobile Company of Asheville, N. C., has taken the agency for the Rambler for Western North Carolina.

The Motor Car Company of Washington, D. C., agents for the Peerless, Thomas, and Stevens-Duryea, has also secured the Buick agency.

In the issue of THE AUTOMOBILE, March 14, it was stated that the firm of Banker Brothers of Pittsburg had taken up the agency for the Aerocar. This was an error. Banker Brothers are agents for the Autocar.

The F. B. Stearns Company, Cleveland, O., makers of the Stearns, has placed agencies with the following houses recently: Wilson Automobile Company, 118 St. Lawrence avenue, Wichita, Kans.; N. E. Peterson, 1520 Belmont avenue, Seattle, Wash.

The Reliance Motor Car Co. has made agency connections with the Fiss, Doerr &

Carroll Horse Company of New York, a corporation handling more horses than any other firm in the world. It is significant that they should show their progressiveness by being one of the first to take up the motor truck.

The Supplementary Spiral Spring Company, 4524-4526 Delmar avenue, St. Louis, Mo., has opened a branch in New York City at 52 West Sixty-seventh street, and Allen McKenzie has been placed in charge. Mr. McKenzie is well equipped to interest the Eastern trade in the springs made by his company and expects to develop the already large demand for them in metropolitan automobile circles.

Joseph L. Keir, the agent for Michelin tires and Rerault machines in Philadelphia, has just opened at 1437 Vine street one of the most complete tire repair works in the country. The factory, which is operated by steam and electricity, is equipped in the most complete manner. The foreman has come from the factory of the Michelin Tire Company in France and will introduce the repair methods so successful in that country.

For the convenience of the trade in Pittsburgh and vicinity the Diamond Rubber Company has established a general agency for its tire and accessories at No. 16 Wood street, that city. This new tire establishment occupies a part of the quarters of the Pittsburg Rubber and Leather Company, which concern has for many years been the agents for Diamond mechanical rubber goods in that territory. A complete stock of tires of all types and sizes will be carried.

RECENT TRADE REMOVALS.

This week the Philadelphia agency for the Knox moved into its newly fitted quarters, 510-512 North Broad street.

The Henshaw Motor Car Company, Boston agents for the Haynes and Columbus electric, has moved into its new store at Massachusetts avenue and Newbury streets, that city.

McDonald, Titus & Co., central Ohio agents for Reo and Mora autos, have leased the four-story building, 61-63 Spring street, Columbus, and will occupy it in its entirety, removing from 138-140 Spring street, where they have been located for several years.

PERSONAL TRADE MENTION.

Freeman L. Loomis has been appointed sales manager of the Reliance Motor Car Company. Mr. Loomis was for twenty years the most active field organizer of the Aultman & Taylor Machinery Company at Mansfield, O.

A. J. M. Edwards, who has been connected with the Electric Vehicle Company since 1899, has been placed in charge of the New York branch, succeeding W. W. Burke, who was recently elected president of the Motor Parts Company.

W. T. Helfer, for many years manager of the Boston branch of the Diamond Rubber Company, and well known throughout the New England States, has joined the Springfield Metal Body Company's selling forces as sales manager, with offices at Springfield, Mass.

"Mike" Costa, a power in Philadelphia cycling trade circles in the last century, has embarked in the automobile business. He has formed the M. J. Costa Motor Car Company at 2117-2121 North Broad street, where he will handle the Bayard-Clement machine in Philadelphia and neighborhood.

R. C. Wright, for the past two years general foreman of the machine and model departments of the E. R. Thomas Motor Company of Buffalo, has accepted the position of general superintendent of the Auto Car Equipment Company of Buffalo, manufacturers of gasoline and electric trucks and sightseeing vehicles.

Thomas S. Witherbee, formerly president of the Witherbee Igniter Company, has engaged in a new business enterprise. He has organized the Witherbee Manufacturing Company, with factory and offices at 433 West Forty-second street, New York City, and will make a new storage battery and several other ignition specialties.

The Dolson Automobile Company of Charlotte, Mich., has made arrangements with F. G. Bremer to take the position as assistant general superintendent of its factory. Mr. Bremer comes from the American Mercedes Company of New York, and previous to his association with that company he was with the Pope-Toledo Company of Toledo, O.

President Percy Neel of the Quaker City Automobile Company of Philadelphia has secured the services of Charles P. Soules, the well-known racing man, to look after the interests of the Pope-Toledo car in that city. In view of the rather comprehensive program of races, hill climbs, endurance runs, etc., outlined by Philadelphia club enthusiasts for the coming season, it is expected that with Soules to guide them the Pope-Toledos will be heard from with considerable frequency.

RECENT TRADE PUBLICATIONS.

Westbrook generators are dealt with in the little folder issued by E. T. Kimball Company of Boston, Mass.

The Stackpole Battery Company of St. Marys, Pa., has issued a folder dealing with their various types of dry cells for automobile and telephone work.

"The Power Behind" has the quality of originality. It deals with the power behind the Wayne automobile, but the way the manner is presented in the little booklet is rather out of the common.

York Pullman automobiles are entertainingly dealt with in the catalogue issued by the York Motor Car Company of York, Pa. The different models are described in detail and illustrated by numerous half-tone cuts.

"Expert Testimony on Springs" is the title of the booklet published by the Perfection Spring Company, 251 Superior viaduct, Cleveland, O. Copies of letters from expert users of the firm's springs are given.

The Gilbert Manufacturing Company of New Haven, Conn., has issued a folder dealing with their Gilbert helmet and the Gilbert Poncho, desirable articles for use in stormy weather, and have also sent out an advance catalogue of their complete lines for 1907.

The Supplementary Spiral Spring Company issued recently a sixteen-page booklet with cover in two colors, which illustrates graphically five different methods of attachment of supplementary springs to cars of different models. The booklet also contains considerable other information, as well as many testimonials to desirable features of this equipment.

"The American Truck" is the title of a pleasing catalogue issued by the American Motor Truck Company of Lockport, N. J. It has been gotten up in the best style known to the typographical expert and very

graphically shows the engine, mechanical parts, complete chassis and fully equipped vehicles for various loads and different classes of business constructed by the American Motor Truck Company.

Owing to the large size and the many articles illustrated, the publication of the 1907 catalogue of Automobile Supplies by the New York Sporting Goods Company, 17 Warren street, New York, is a little later this year than usual. They announce, however, that their "big book" is now ready and everyone is invited to write for a copy. This company has for years made a specialty of the bicycle trade and are probably the largest handlers of these goods in the east. They control many valuable agencies, including the Pittsfield Spark Coil Company's goods and Hudson bicycles for the Middle Atlantic States. The automobile supply catalogue is known as No. 37 and the bicycle catalogue as No. 38, and they may be had without charge on application.

The Cleveland Motor Car Company's catalogue combines a description of what the car is and what it does. The former is related in text and excellent half-tone illustrations and the latter is an account from the pen of Walte Hale of a run from Gibraltar to the coast of Normandy in a Cleveland car. It is a racy written description of a unique tour and is embellished with photo engravings and pen sketches of scenes in romantic Spain and historic quarters of France. The account of the tour will interest every man who possesses anything of the roving spirit, whether he has any love for carbureters and coils or not. The analysis of the Cleveland machine is so skillfully done that even the indifferent should find it attractive.

A PHENOMENAL GROWTH.

Though young in years as compared with other industries, the business of supplying, or rather, jobbing, automobile parts and accessories, is one of the most solidly founded in the country to-day, and not the least of its husky infantile representatives is the Neustadt Automobile and Supply Company St. Louis, Mo. From a diminutive, though vigorous beginning, this company has gone forward with such strides as now to occupy a place all its own in the automobile economy of the Middle West, and from the Mississippi to the

Coast. The accompanying illustration gives but a poor idea of the extent of the establishment now occupied exclusively by this concern, which has made a practice of "supplying everything for the automobile" ever since it started, and not content with living up to its motto in a manner equaled by few, has now added a full line of motor boats and accessories in the shape of an independent department devoted to this line. The company anticipates a most successful season, and with the aid of the recently enlarged facilities expects to attract a larger number than ever of tributary buyers to their natural market—St. Louis.

INFORMATION FOR AUTO USERS.

Woodworth Treads and "Kant-Skid" Grips.—The 1907 Woodworth tread has a new method of adjustment, the side wires being made of spring steel crimped or wavy in shape, so that they are self-adjusting and take up the slack automatically. The covers have short straps along the edges, with buckles having hooks on the back to hook

WOODWORTH TREAD ATTACHED TO TIRE.

over the wires. Adjustment for different size tires is made by arranging the buckles on the strap at the proper distance from the edge of the cover.

The nature of the "Kant-Skid" tire grip is self-explanatory. It consists of strips of chrome leather 1 1/4 inches wide, studded with steel rivets placed across the tire about four inches apart. A steel plate riveted under the studs protects the leather and gives additional durability to the device. The cross strips have rings at each end, connected by spring steel links, which can be snapped into place in one second. To make the skid bands fit different size

SECTION SHOWING "KANT-SKID" ATTACHMENT.

tires it is only necessary to add or remove one or more sections. The spring side links enable one to do this or to put in new cross pieces to replace worn ones. These straps across the tire present a soft surface to the rubber and cause no injury. They can be used equally well on solid tires without danger of cutting. Both of the above popular appliances are manufactured by the Leather Tire Goods Company, Newton Upper Falls, Mass.

"Oilers" for Wet Weather.—That old-time and well-tried waterproof garment, the Gloucester "slicker," has yielded to modern conditions. Instead of the shape-

less oilskins familiar to fisher-folk, we can now have stylish and well-fitted garments made from this material. There is also a new creation in an automobile reversible coat, made with one side of mercerized silk or khaki, and the other side of oil-coated muslin, giving a silky finish. The silk or khaki is left in its natural state, no oil or rubber being used, giving a garment for pleasant weather. The waterproof side, entirely free from the cloth side, is made of fine muslin coated with oil by the Boynton patent process, giving a soft, silky finish. This combination of silk or khaki for one side and a finely finished oilskin for the other gives a slightly garment for all kinds of weather. They are made by the Boynton's Improved Process Oil Clothing Company, Gloucester, Mass.

Handy Dry Battery Connectors.—A clever device that gives a good contact, a quick connection and a wire lock, all these conditions being inter-communicating, is the Standard battery connection. It is made from one piece of brass cut and die-shaped to give this service. At the bottom of the loop is a hole just large enough to permit easy passage over the threaded pole connections. About midway up each arm is an inwardly projecting lip. One arm

NEW DRY BATTERY CONNECTION.

has a slotted end and the other a finger end to form a dovetail joint. By passing the finger through the slot the midway lips act as locks on the threads of the terminal. The connecting wire bridges the dovetail ends, reacting against the locking lips below them, which in turn pull the dovetail apart, only to more securely hold the wire connection. These handy little connectors are made by the Standard Battery Connection Company, 27 Copeland street, Roxbury, Mass.

Emergency Spring Repairer.—Fortunately it is not very often that the automobilist has need of a temporary spring repairer, but when he does want it he wants it mighty bad. The engraving herewith explains clearly the nature of the spring repairer and its method of attachment. The cut is reproduced from a photograph of a broken spring and "Emergency Spring Repairer" which was attached to a five-pas-

EMERGENCY SPRING REPAIRER.

senger 35-horsepower car, which was run over 843 miles on all kinds of roads before the spring was replaced by a new one. The

appliance is simple and light and occupies so little space that it can be advantageously included in every equipment. It is made of steel and in sizes to fit every spring. When ordering, the width of spring clips is the only dimension that needs to be given. This appliance is being handled by the Emergency Spring Repairer Company, 5 Beekman street, New York.

An Electric Lamp Lighter.—Using a jump spark gap to light the acetylene burners is the explanation of this device. The burner outfit has an insulating sleeve, which

NO-MATCH ELECTRIC LAMP LIGHTER.

supports the metal arms carrying the "spark points." The spark gap comes over the gas vent on the lava tip of the lamp. With one of the arms grounded, the other is wired into the secondary circuit of the spark coil. From the primary circuit a lead is carried to a push button at any point convenient to the driver. Pressing the button closes the circuit, a spark occurs across the gas vent and the lamps are "lit while running," the gas also being turned on from the seat. This hand device is manufactured by the No-Match Electric Manufacturing Company, 141 Milk street, Boston, Mass.

A Unique Town and Country Signal.—Leavitt's latest is a combination which is a clever uniting of a siren and a reed horn. Its ownership means the possession of a signal for country and night riding and a horn for city use. As indicated by the name, this is another of the Leavitt novelties, made by the Uncas Specialty Company, Norwich, Conn. The combination is arrived at in a manner both simple and ingenious. Around the throat of the siren portion are carried the coils of the reed part of the horn. At the bend of the throat

LEAVITT'S COMBINATION HORN.

the coil passes through the wall to its bell, which is placed concentric with and inside the siren bell, the two being closed in with the usual screen. Attached to the reed coil is the usual flexible tube and hand bulb. The flexible shaft attachment for the siren portion is particularly good. The shaft itself attaches at both ends by a simple jaw clutch and friction pulley is adjust-

able, and its bearing block resting in a broached hole it becomes positive at any position. The arm carrying this block pivots at its other end in a bracket, which screws to the under side of the floor boards. At the end in which is secured the bearing block the return spring is placed. There is also a free foot slinger for holding the pulley into contact with the fly-wheel.

The "Krackerjack" Jack.—Although closely resembling last year's model, the "Krackerjack" jack has undergone important changes. Pressed steel is now employed for the entire frame, giving mini-

SIDE VIEW OF KRACKERJACK.

mum weight and maximum strength. The rack bar is of high-grade carbon steel, with the teeth milled out, thereby disposing of any liability to crack or break. The rack bar may be had with or without secondary lift. The internal mechanism is composed of drop forgings carefully ground and fitted, removable at will as if in one piece. A steel pin, provided with a shoulder on one end and a split pin on the other, supports the mechanism in the frame. Raising and lowering is performed in the usual manner, but as the lever handle is inserted close to the base increased ease of operation is secured. To reverse the action it is only necessary to make a one-eighth turn of the handle, thus allowing the load to come down slowly. The manufacturers and selling agents of the jack are the Utility Company, 332 Broadway, New York.

A Flexible Carbureter.—The main feature of the Palmbla carbureter, manufactured by the North Chicago Machine Co., is the departure from the accepted methods of producing carburetion by having the fuel aspirating nozzle in the air passage. The multiple jet fuel nozzle is placed above the air passage and mixing chamber and the intake valve is controlled by a calibrated compensating spring. Under such conditions the suction stroke of the motor causes a varied vacuum in the body of the carbureter, and is proportionate to the piston speed. This automatically governs both the supply of the air and the fuel, the mixture being constant under all speeds. The use of an auxiliary air valve is eliminated, as in this system the carburetion process is controlled wholly by vacuum

in the mixing chamber rather than by the speed of the air in passing the fuel nozzle. The makers claim that this carbureter is sufficiently flexible to meet the requirements of their convertible two or four-cycle motor.

A Novel Power-Driven Tire Inflator.—It has come to be a trite saying that more tires are ruined by lack of proper inflation than are ever worn out in use, for the pneumatic tire should be inflated to the pressure

SIDE VIEW, SHOWING CRANK.

it is designed to carry at all times. But with the increasing sizes now customary on modern cars the work of hand inflation has come to be so laborious that it is more often slighted than otherwise, with resulting punctures and rim-cutting. To remedy this a Chicago firm is placing on the market a compact and powerful inflator under the name of the "Rotary Triplex Tire Inflator." It consists of a small cylindrical casing mounted on the crankshaft bracket at the forward end of the radiator, and

END VIEW WORKING PARTS UNCOVERED.

contains three short cylinders and a close-fitting annular gear running on three-point roller bearings, eccentric to the inner walls of the housing, to which the piston rods of the cylinders in question are attached by hinged joints. The rotation of the gear ring carries the cylinders about their axes with it, the air pressure thus generated is delivered through the cylinder heads to the hollow shaft on which they are mounted and from which a connecting tube is led to the tire to be inflated. The pump is permanently attached to the car and is put into action simply by shifting the position of a cotter pin before cranking

the engine to start. The same makers, Skinner & Skinner, 1337 Michigan avenue, Chicago, also list a handy pressure indicator for use in connection with the inflator. The illustrations show the small size and simplicity of this convenient pump.

Postal is the apt and expressive title of a new entrant into the field of what has come to be known as the "buggy-about." It is manufactured by the Postal Auto & Engine Company, of Bedford, Ind., and, as its name indicates, it is designed to be capable of that rough-and-ready service which calls for the almost infallible reliability of the postal service. The motor is of the double-opposed horizontal, four-cycle type, air-cooled, and is rated at 12 1-2 horsepower. The transmission is of the planetary type, giving two speeds forward and reverse with a final drive by steel cables. Suspension is by means of two semi-elliptic, inverted springs, 70 inches long, with their ends resting directly on the 1 1-4 inch square section steel axles. The muffler, carbureter and coil are of the best known makes, lubrication being effected by a standard automatic system. The running gear consists of 42-inch front and 44-inch rear Sarven patent wheels, shod with 1 1-8 inch solid rubber tires, brakes being placed on the transmission and the counter-shaft, the latter carrying the emergency. The total weight is 900 pounds and the speed up to 30 miles an hour.

Miller Speed Meter.—A twelve months' guarantee, provided the seal is not broken, is given with every Miller speed meter manufactured by Charles E. Miller, 97-101 Reade street, New York. This speed indicator will register as low as five miles an hour and up to sixty miles an hour, or 100 miles an hour if specially ordered. In addition to showing the rate of speed traveled at any given moment, an odometer attached registers the trip and gives a permanent record up to 10,000 miles. The interior mechanism works on centrifugal principle. The governor spindle is made of tool steel, hardened and ground to size, with fly balls and links of brass. The speed meter is made to be attached to the dashboard and is actuated by means of a flexible shaft and crown gear wheels at-

tached to the front wheel of car. The large gear to be attached to the hub is so made that it can be fitted to any of the domestic or imported cars without extra attachments or fittings.

THE AUTOMOBILE

A STATE UNIVERSITY WHERE
AUTOMOBILING IS TAUGHT.

By HAROLD W. SLAUSON.

IT may be that some day in the near future the meaning of the "A.B." degree will be changed from Bachelor of Arts to Bachelor of Automobiling. Cornell University in the past two years has introduced into its curriculum a practical course on automobile construction, which is practical in every sense of the word, so much so that the work is made extremely interesting as well as instructive. Professor Rolla C. Carpenter is the head of the Department of Experimental Engineering and a recognized authority on mechanical matters, and incidentally is the consulting engineer of a widely known company making steam automobiles. Cornell's automobile course consists of two lectures a week, given throughout the second half of the year, and every detail of the modern automobile is discussed.

The Course is Most Thorough and Complete.

The history of each part is thoroughly gone into, and the improvement in design, from its inception to present-day perfection, is carefully studied. The same method is pursued with the unsuccessful or discarded attachments, the reasons for their failure carefully investigated, and the young designer forewarned against "freak" innovations which have threatened to "revolutionize the motor industry." Of course, incentive for original research and design is given, but in such a way that it will lead through channels where the greatest good can be accomplished without going over the ground already trodden by unsuccessful attempts.

After all of these parts are investigated in detail, the assembled chassis as a whole is studied, the best materials to be used for frame, gears, shafts, etc., is determined, and then the student is ready for investigation in the construction of the leading makes of cars, both foreign and American. This study is greatly facilitated by the use of stereopticon views, which consist of several pictures of the make under consideration, showing the car as a whole, the chassis and any feature peculiar to that make.

Another course in the university which may well be taken in conjunction with the course above mentioned is a series of lectures in gas engine design, or "internal-combustion motors," as it is officially called. This is given by Professor Herman Diederichs, who is unusually well equipped to give a course on this subject, having made a study of the gas engine from both a theoretical and practical point of view. Professor Diederichs is a collaborator with Professor Carpenter in an exhaustive treatise on the internal combustion motor, now in the press. As its name indicates, this course of lectures, of which there are two a week during one term, devotes itself exclusively to the study of the gas engine, and includes the stationary and marine, as well as the automobile types.

While this is not entirely a theoretical course, formulæ for the design of all parts of a motor are not only learned, but derived as well, and standard measurements and proportions as adopted by the leading makers are discussed and investigated. It is in this course that the student can realize what the automobile has done toward the development of the internal combustion motor, how the weights of the materials used have been reduced, the qualities of the metals improved, the entire machine simplified by the elimination of unnecessary parts, and the increase in accessibility.

Not the least valuable part of this course is the study which is made of the theory of combustion, and the chemical changes which take place in the cylinder of a gas motor. This naturally leads to an investigation of the efficiency of the various fuels, and tables and data are given showing the performance of motors using every kind, from ether to alcohol, and from crude oil to kerosene. Particular attention has been paid to the use of alcohol as a fuel, especially since the free alcohol bill was passed.

Another interesting phase of these lectures is the theoretical investigation of the comparative efficiencies of the two and four-cycle engines for all kinds and sizes of work, from the small motor-cycle engine to the mammoth power-plant engines as used

TWO-CYLINDER WESTINGHOUSE RIGGED FOR TESTING.

The pump shown at the left of the engine is used as a dynamometer, the amount of water pumped in a given time being found, and this reduced to the horsepower that the engine develops.

to a great extent in Germany. Taken all in all, this course, if entirely mastered, would give the student a keener insight into modern practical gas engine building than months of study of the best books and investigations at the different shops.

The foregoing courses, it will be noticed, consist mainly of lectures, where the student absorbs, as it were, the information gleaned by others without putting his knowledge to any practical use. In the course on "Gas Engine Design," however, which is given under the direction of the Machine Design department, opportunity is found for the application of all the knowledge available on the subject, for the student here designs a practical engine. The size and purpose of the motor are first determined, and then, applying the formulæ and methods of design learned in the lectures, the student makes working drawings of the complete gas engine, including every detail of dimensions, kind of material to be used, and finish. These drawings are required to be so complete that they could be sent to a foundry and a practical engine turned out from these specifications.

While, of course, modern practice and conventions are followed to a great extent, there is opportunity given the student to exercise his own ingenuity in original design, and possibly the solution of many of the problems which now confront the gas en-

OHIO GAS ENGINE RIGGED FOR TESTING.

Showing dynamometer on flywheel and apparatus for obtaining indicator cards

gine builder may be unexpectedly discovered in this drawing room. Now for the practical side of the course—for no investigation would be complete without the experimental proofs of the deductions and conclusions reached from the theoretical study. This is found in the Mechanical Laboratory, which is the most complete of its kind of any technical school in the country. The leading makes of two and four-cycle engines are here tested under different conditions of load, speed, fuel and the like, and the most efficient speed and load at which each model should be run is thereby determined. This testing of gas engines is included in the regular course of testing all kinds of machinery, and is required of all engineering students, be they mechanical, electrical or marine. These tests last throughout the Junior and Senior years, and each student is required to complete one a week. This course is extremely interesting, and is merely an application of the methods learned in the class rooms as a means for teaching original investigation and arriving at practical results.

It might be interesting to note that one of the first gas engines to be used in this country is on exhibition in this laboratory, and the contrast between this cumbersome machine and the light, four-cylinder automobile engine near which it is placed is striking. This parent of the modern automobile power plant consists of a single vertical cylinder, which is inverted—that is, the explosion forces the piston up instead of down. This piston is very heavy and has a connecting rod which consists of a rack or heavy rod, with gear teeth cut in it transversely. These teeth mesh on the down stroke with teeth cut in the shaft of a heavy flywheel. When the explosion takes place, the piston and rack are forced up, and when the exhaust has occurred the weight of the moving parts provides the force which revolves the flywheel by means of the rack meshing in with the gear only on the down stroke. It will be seen that the explosions are utilized only to move the weights up to a position where they can perform their work, and that not only must the speed of the engine be necessarily slow, but the power of the engine small, considering its weight and size.

Ithaca Has Many Autos and Much Enthusiasm.

One familiar with the locality would hardly consider the central part of New York State an ideal place for automobiling. And it isn't—steep hills are as frequent as good roads are scarce. By the central part of the State is not meant the vicinities of the larger cities such as Syracuse, Utica and Rome, but more what is known as the lake region. Here is to be found some of the most beautiful scenery in all of the Eastern States, and it is this combination of hill and valley, ravine and lake that makes the hills and roads what they are—and aren't.

Notwithstanding its location in the heart of this region, at the head of the Cayuga Lake, Ithaca can boast of as many automobiles and as many auto enthusiasts as any city of its size in the State, and possesses an automobile club which has done much to popularize both automobiling

PROF. ALBERT W. SMITH,
Director of Sibley College.

PROF. ROLLA C. CARPENTER,
Head of Department of Experimental Engineering, Sibley College.

and motor boating. But the heart and source of this interest lies "On the Hill"—in fact, the heart of Ithaca lies on the hill—for it is with the faculty and students of Cornell University that much of this interest centers. In fact, practical automobile construction and design are taught there. To be sure, no chauffeur's degree is conferred, but many of the recent graduates bearing the M.E. degree know more about gasoline motors and motor boats than they know about steam engines or calculus.

MR. WINKLEY'S IDEA.

Recently, before the Ad Men's Club of Boston, Robert L. Winkley, manager of publicity of the Pope Manufacturing Company, said in the course of an address:

"There is no kind of publicity, whether it be direct or indirect advertising, so valuable as that which comes by word of mouth. The friendly comment and advice of a satisfied customer is far reaching and of great value. I believe that the trade papers do more to stimulate that word-of-mouth publicity than any other line of publications, because they go directly to the salesman, dealers and buyers throughout the country, and they act as a sort of medium of communication between these people, and what they have to say and do in the trade is an important element in shaping the conditions of the trade."

IMPORTERS' SHOW NOW REGARDED AS CERTAIN.

The announcement of the Association of Licensed Automobile Manufacturers that it will hold its show in November instead of January has roused the importers of foreign cars to action, and they are united in their declaration that an exhibition of imported cars at a later date will be a necessity. The sentiment as generally expressed in New York City is in favor of a show for foreign cars of all makes, whether sold here under the Selden patent license or not, though several importers express their strict loyalty to the A. L. A. M. and state that licensed and unlicensed imports should be kept separate.

One of the leading importers of licensed cars made the following statement: "It will be a physical impossibility to have 1908 models of foreign cars here by November, or even by December. There are eight importers of twelve makes of cars in the licensed group and they could make a fair show by themselves. But if all the importers got together a representation of from forty-five to fifty makes of foreign cars could be displayed. It is a question whether the A. L. A. M. would consent to the use of the Garden if unlicensed cars were to be shown there, but probable that that privilege will be sought."

At a meeting of the Importers' Automobile Salon to-night this matter will be discussed.

GAS ENGINES FOR BRITISH WARSHIPS.

LONDON, March 18.—The shipbuilding and gunmaking firm of Vickers Sons & Maxim, after three years' continuous research, has perfected a system of propelling war ships by means of internal combustion engines. A vessel of this type has been designed, which, having no boilers and no smoke stacks, will have enormous advantages over existing battleships. Her dimensions are moderate, but she is speedier than existing ships. Her battery is more powerful than that of the Dreadnought class, since, owing to the absence of smoke stacks, all ten guns can be fired on either beam and six of them ahead or astern.

A paper recently read before the Institution of Naval Architects predicted that warships in the future would be propelled by gas engines instead of steam. British naval authorities are now considering the adoption of motor boats on warships.

LOZIER MARINE ENGINE RIGGED FOR TESTING, IN SIBLEY COLLEGE LABORATORY.

EARLIER DATES FOR GARDEN AND COLISEUM

THE 1908 product of the American automobile manufacturers will be on view, both in New York and in Chicago, before the close of the present year. The Madison Square Garden show of the Association of Licensed Automobile Manufacturers will be held from October 31 to November 7, and the exhibition of the National Association of Automobile Manufacturers will take place in Chicago from November 30 to December 7.

It would appear that the latter date would conflict with the show of the Automobile Club of America, supported for the past two years by the American Motor Car Manufacturers' Association, and for which dates have been reserved in the Grand Central Palace from November 30 to December 7. It is probable and possible that the A. C. A. may advance its dates in view of the move of the A. L. A. M., and it is understood that the A. M. C. M. A. has prepared itself for any revision of the show situation. Alfred Reeves, its general manager, is expected back from a Western trip to-day, and a conference of the A. C. A. Show Committee is expected to follow. There has been some talk that the anti-Seldenites might promote an outdoor exhibition in November, but apparently this has never progressed beyond the mere suggestion.

How the A. L. A. M. Show Announcement Reads.

From E. H. Cutler, chairman of the Executive Committee of the A. L. A. M., on Monday came the following announcement:

"At the last meeting of the Board of Managers of the Association it was unanimously agreed to have an early show if suitable dates could be arranged. The Licensed Association has an option on Madison Square Garden for automobile shows for two years, and it was only a question of an arrangement of dates to proceed for an early show. Negotiations were completed on Saturday, and arrangements made for October 31 to November 7.

"The success of the last show in the Garden, where the attendance was so great that it was necessary to increase the admission for two days to \$1, has suggested the possibility of a ten-day show. The advisability of this is still under consideration by the Association.

"The show situation has so materially changed in recent years that an early show seems advisable. The demand for early deliveries of standard cars has been in part responsible for the Association of Licensed Automobile Manufacturers' change to early show dates. For years the tendency of automobile shows has been to particularly interest the dealers, but now that the industry has settled on a firm and conservative basis, contracts for the year's output of the various factories are usually made long before the end of the year; in fact, most of the cars for the fol-

lowing year are tried out long before November and December. The standard time which various manufacturers would naturally consider the best time for the showing of the following year's models would be based on a standpoint of knowing early enough what the people desired in the way of special specifications. Early shows would give ample time for purchasers to get in specifications, so that the factories would not be taxed to the limit of their capacity in getting out cars for delivery the early part of the spring."

Explaining the Whyfore of Earlier Chicago Dates.

From S. A. Miles, general manager of the N. A. A. M. and also manager of the Chicago show, comes the following pronouncement:

"The Eighth Annual National Automobile show at Chicago will be held at the Coliseum and First Regiment Armory, November 30 to December 7, as usual under the auspices of the National Association of Automobile Manufacturers, Inc. As was the case in February, the Chicago show will be the only truly national event of the year, for it will be the only one which will bring together all makes of cars, regardless of the affiliations of their makers with any other association.

"The early date has been selected only after careful consideration. There are a great many people in the trade who still believe that February, or even a later date, is the proper time for the show, but the expression of a desire for an early date has been so general that it has been deemed fair to early show advocates to give it a trial. The New York shows are to be held late in October or early in November, so that there will be the usual interval between New York and Chicago. The request made by the Chicago Automobile Dealers' Association was also an important factor in determining the date.

"It is probable that the allotment of space will be made about the first of September, though an earlier date may be selected."

May Embarrass the Foreign Makers.

Earlier dates for the New York and Chicago shows may seriously embarrass the foreign makers, for it will compel them to turn out a double set of models in order to exhibit their up-to-date machines in this country. The Paris Salon has already contracted for November dates and will continue for twenty days and lap into December. London's show is even earlier. Exactly how the foreign makers will meet the situation is somewhat problematical, but it is a certainty that they will contrive in some manner to figure in the American shows, for the market in this country is too valuable to be sacrificed without a big effort.

EUROPEAN MAKERS ARE UNITED ON SHOW DATES

REGULARLY every year, with the single exception of 1898, when the show was held in the month of June, Paris has held its automobile salon early in December. Once, in the early days, the unanimity of the constructors was destroyed and two rival shows were opened. For ten years, however, all has worked harmoniously, the Automobile Club of France organizing an annual show with the double object of exposing the latest models of automobiles and of impressing the public with the value of the new means of locomotion. It is this latter policy which has done so much to make the show the important demonstration it is to-day. It has been lifted above the level of a trade organization and made a public demonstration that no up-to-date person dare admit he has not seen. Other countries have either not grasped the value

of this line of procedure or have been unable to carry it out on account of local circumstances.

From December 8 or 9 to December 23 or 24 has been mutually and unanimously agreed upon as the most suitable date for the holding of the Paris show, and not even the proposition of a change would have been thought of had not the London show authorities, out of commercial rivalry, attempted to get ahead and transfer the world's market to the other side of the Channel. London, which up to 1895 had held its annual automobile exhibition after that of Paris, advanced its date to November with the avowed purpose of making French constructors show their new models in England before they were exhibited in Paris. The move succeeded to a certain extent, for unwilling to be behind on such an important market as is Great Britain, French

makers put forth a special effort and finished some of their following year's models in time to be exposed at the earlier show. Contrary to what had been expected, however, the French club did not respond to the British challenge by altering the date of its show; the announcement that this year's Paris salon will open in November instead of December is due entirely to the fact that it is the decennial show and will be celebrated with increased éclat.

French constructors are almost unanimously of opinion that it is impossible to produce the following year's models conveniently before the end of November or beginning of December. All European factories, for instance, are now working on their 1907 output and will continue to be busily employed thereon until early August. The selling season then being practically over, attention can be paid to the designing and construction of new types for 1908. Four months in which to design, construct, try out and give a show finish to two or three new models is not too long a period for even the best equipped factories. This is proved by the fact that the French makers are never ready for the show until a few days before the doors are thrown open. If the annual exhibition were held later there would not be sufficient time for agents to make sales and for the factory to fulfil orders early enough in the touring season to satisfy the public. From the standpoint of the salesman London's move in holding the show in the middle of November was commendable; but the same qualification cannot be applied when the constructors' interests are considered. In the last analysis it is best for all concerned that new models should be thought out when the factory is least occupied with pressing work. That period is at the end of the summer, and as a consequence the time of year for bringing out the new finished production is as late as possible in the year as is compatible with deliveries in time for the following season. There is nothing to be gained by holding an automobile show earlier than the beginning of December and French manufacturers are fully aware of it.

REPORT OF THE YEAR'S WORK AT HARTFORD.

During the past twelve months the Hartford laboratory of the mechanical branch of the Licensed Association of Automobile Manufacturers has been busily engaged in experimenting along various lines, and has just issued a report of the results of its work to the members of the association. Materials have chiefly occupied attention, and during the year scores of samples of special steels of various grades have been tested in various ways to ascertain the best method of bringing about the toughest possible condition of the metal. Among the alloy steels experimented with were nickel, chromium, chrome-nickel, silico-manganese and vanadium, particular attention being given to the latter. Some of the members of the association have been using vanadium steels in their cars, but the experiments having proven the great desirability of its extended use in the making of certain parts, the association has recommended its universal adoption by the members, as it is considered to be more serviceable than any other metal known. Specifications for the treatment of metals, screw material, cast iron, steel and nickel castings, with directions for obtaining the best results, have been issued in connection with the report. Not long ago the entire mechanical branch spent the day at the Bethlehem Steel Works inspecting the methods employed.

Among other things recommended in the report as the result of investigation during the past year are the adoption of a standard form of magneto base and a standard drill size, as there was found to be considerable variance in the use of taps and drills. A new feature about to be established will be the Technical Library of the Mechanical Branch, which will be installed at the association rooms under the supervision of the secretary, Coker F. Clarkson. As the first and only library of its kind, every effort will be used to make it as complete as possible, experiments, tests and formulæ emanating from the association laboratory at Hartford and from those of the makers being carefully tabulated.

PREPARING FOR THE MONTREAL SHOW.

MONTREAL, March 25.—R. M. Jaffray, director of the Montreal Automobile and Sportsman's Show, which will open at the Arena April 6, is a mighty busy man these days preparing for what promises to be the most notable automobile event ever held in Canada. While at the Boston show Mr. Jaffray obtained some new ideas, which will be utilized in the conduct of the local exhibition. The new annex is nearing completion, and the Arena will be tastefully decorated for the occasion.

One of the most interesting features of the automobile business in Montreal is the double expenditure necessitated by advertising in newspapers of two languages, English and French, caused by the large French speaking population.

SOME PITTSBURG SHOW PRELIMINARIES.

PITTSBURG, PA., March 25.—The Automobile Dealers' Association has invited the Mayors of Pittsburg and Allegheny to open formally the first automobile show in this city, beginning April 8. Governor Stuart and Lieutenant-Governor Murphy have also been invited to attend. The clubs of the Pennsylvania Motor Federation have been asked to send representatives and a meeting of this body will take place during the show.

DUQUESNE GARDEN, WHERE PITTSBURG WILL HOLD ITS SHOW.

The Liberty Automobile Company has completed arrangements for a thousand-mile non-stop run by a Wayne car. The run will begin April 4 and it is expected that a thousand miles will have been covered by the time the show opens. The car will then enter the Duquesne Garden and its motor will continue to run until it stops of its own accord. Various features will be employed in calling attention to the performance, including a guessing contest as to the distance covered every six hours and the time the motor will continue to run in the Garden.

Despite the fact that the Motor and Accessory Manufacturers declined to grant a sanction for the show, there will be a substantial line of accessories, including several displays of tires. The Show Committee, consisting of Thomas I. Cochran, W. H. LaFountain, Earl Kiser, W. N. Murray and Robert J. Sample, are sparing no expense in the work of preparation, and the Garden will be decorated in white and green, and 10,000 electric lights will add to the splendor of the affair.

The following dealers will exhibit: American Automobile Co., Allegheny Automobile Co., Atlas Automobile Co., Auto Repair Co., Banker Bros. Co., Colonial Automobile Co., D. P. Collins, Central Automobile Co., East Liberty Automobile Co., Forest City Automobile Co., Fort Pitt Automobile Co., Hiland Automobile Co., Homewood Automobile Co., James Motor Co., Keystone Automobile Co., Liberty Automobile Co., E. Nevin, J. E. McNary Co., Pennsylvania Automobile Co., Pittsburg Motor Vehicle Co., Rainier Automobile Co., Standard Automobile Co., Union Automobile Co., Wilkesburg Automobile Co., Winton Motor Car Co., M. H. Page.

TENDENCIES OF FRENCH AUTO CONSTRUCTION

By W. F. BRADLEY.

AS an indication of the tendency of the best European constructors, the annual statistics compiled by M. Lucien Périssé on the Paris automobile show have more than a passing value. The last Paris show contained 150 constructors, 60 per cent. of which were French makers of complete chassis, 13 per cent. makers of motors and different parts and 27 per cent. foreign constructors. Of the 60 per cent. just mentioned, 54 per cent. consisted of internal explosion motors and only 6 per cent. steam, electric or mixed systems.

Leaving aside the exhibitors of assembled machines and a certain number who exposed complete cars having no distinctive features, 65 French constructors exposed 149 different types of automobiles driven by internal combustion motors. Comparing these 1907 models with those shown during the previous four years, the following table is obtained:

Four-stroke motors—	1902	1903	1904	1905	1906
One cylinder	12	15	6	8	6.5
Two cylinders	37	26	15	20	11
Four cylinders	48	55	76	71	75
Three or six cylinders	3	4	3	1	7.5
Automatic inlet valves	55	33	3	6	6
Mechanical inlet valves	45	67	97	94	94
Separate cylinders	35	33	33
Cylinders in pairs	65	63	59
Cylinders in one casting	4	8
Ignition by magneto, make-and-break	22	32	26	39	24
Ignition by magneto, with plugs	0	6	23	45	72
Ignition, various	4	1	2	5	0
Accumulators	74	71	49	11	4

The show always being held in December, these figures refer to the succeeding year's models; 1906 figures, for instance, deal with 1907 machines.

In spite of the increased importance of six-cylinder engines, the four-cylinder type still remains the most popular for touring machines. The percentage of single-cylinder engines still remains high owing to the fact that several makers of light cars have adopted the De Dion engine, which is counted as a different type on each maker's chassis.

Considering the nominal horsepower of the machines—that is, the horsepower indicated in the catalogues—it is still the 24-30 type which has the largest number of representants.

Classifying the motors by their bore, the following figures are obtained:

	Per Cent.
70, 75 and 80 millimeters	7.0
84, 85, 86, 87 and 90 mm	22.5
95 and 100 mm	22.5
105, 108 and 110 mm	13.2
112, 113 and 115 mm	7.0
120 mm	13.2
124 and 125 mm	4.0
130 mm	3.3
140 mm	3.3
145, 150 and 160 mm	4.0

No horizontal motors were shown. Comparing these figures with those of the London show, in which British and foreign machines were exposed, we find that in the British capital 72.5 per cent. were four-cylinder machines and 4.5 had single cylinders. The percentage of horizontal motors was 4.5, as compared with 11 per cent. in 1905. At the London show 55 per cent. of the machines had double ignition. At the Paris Salon all the builders with a very few exceptions were of the opinion that double ignition is now superfluous.

Considering the construction of the engine, we find that 39 per cent. of the motors had valves all on one side—that is, they had only one camshaft. Motors with valves on opposite sides and consequently two camshafts were 55 per cent. of the whole, while only 6 per cent. of the motors had their valves in the head. Compared with the figures for last year's show, it is seen that the proportion of machines with a single camshaft has sensibly increased. In two-thirds of the machines a governor was provided; in one-third it was not used.

Methods of cooling have little changed since last year. Air-cooled motors are practically non-existent. Thermo-siphon water circulation was employed on 14 per cent. of the engines and centrifugal pump on 67 per cent. The majority of the pumps were driven direct or through gears within the crankcase. One per cent. of the pumps had friction drive and 5 per cent. had springs. The honeycomb radiator is distinctly on the down grade, its proportion being 40 against 59 per cent. of winged and tubular radiators. One per cent. were various systems. The fan behind the radiator was most frequently found, 63 per cent.; 15 per cent. had the fan within the flywheel and the same percentage had the two systems.

Pressed steel frames continue their progressive march and have almost abolished the tubular frame. The latter is only used now for sub frames. The following figures show the tendency in frames and clutches:

	Per Cent.			
	1903	1904	1905	1906
Pressed steel frames	46	76	82	90
Armored wood	32	16	14	10
Tubular and various	22	8	4	..

	Per Cent.				
	1902	1903	1904	1905	1906
Leather faced cone clutch, right	74	80	60	51	54
Leather faced cone clutch, inverted	13	10	17	15	10
Metallic clutches	20	32	36
Various types	13	10	3	2	..

There were a few special types of change-speed gears, such as the Fouillaron, with belt and extensible pulley, and that presented by the Swiss firm Turicum, but they were such a small number that they need not be considered. Change-speed gears of the sliding type can be classified as follows: Single sliding gear, 46 per cent.; double sliding gear, 31 per cent.; triple sliding gear, 22 per cent. One per cent. consisted of various systems. Direct drive on the high gear and the use of ball bearings remain as before, namely 88 per cent.; 2.7 per cent. of the machines under review carried the gear box within the rear axle casing, among them being the Henriod and Gillet-Forest.

The cardan shaft shows a large numerical superiority over final drive through side chains. This is partly accounted for by the fact that at the Grand Palais nearly every constructor showed a chassis intended for cab work or town use. For this class of vehicle the cardan shaft offers distinct advantages over chains; several important firms, among them Mors, C. G. V. and Fiat, have indeed not hesitated to adopt this type while maintaining side chains for their more powerful touring cars. The percentage of machines with chain and cardan shown during the last six years is as follows:

	1901	1902	1903	1904	1905	1906
Side chains	50	62	53	49	48	37
Shaft drive	44	35	47	51	52	63

De Dion-Bouton machines have double shaft; a few firms, among them Aries and Chenard & Walcker, have special rear axles and a few Lyons firms have direct drive on third speed.

Internal brakes were in a large majority, for they represented 90 per cent. of the total, a figure distinctly in advance of last year. External brakes were only used in a few special cases or on cheap cars. There was a strong tendency towards the use of soft metals for rear wheel brakes. Where the brake consists of steel on steel the band was always of a softer steel than that used for the drum. The metals used for all types of brakes were as follows:

	1906					
	1903	1904	1905	Wheel Brakes	Trans-Brakes	Average
Cast iron on steel	0.26	0.36	0.51	0.43	0.45	0.465
Bronze on steel	0.17	0.17	0.32	0.25	0.23	0.265
Steel on steel	0.33	0.30	0.13	0.21	0.22	0.215
Various	0.24	0.07	0.04	0.06	0.05	0.055

HOW LEVAVASSEUR BUILT HIS LIGHT MOTOR

By CAPTAIN FERBER.

PARIS, March 20.—With the prospect of the problem of aerial navigation being solved in the near future, it is interesting to note how Levavasseur, the French engineer, constructed his first extra light motor, now being used by Santos-Dumont and other pioneer aeroplanists. Captain Ferber tells the story as follows in a recent number of *Omnia*:

My friend Archdeacon is to blame for whatever has been done, for he got it into his head that if I met Levavasseur some good might result to the cause of aviation. At that time no automobile constructor had paid any attention to flying machines, and I had wondered if I should have to build an engine for myself. In 1903 I had tried a 6-horsepower Buchet and in 1905 a 12-horsepower Peugeot. Power had been doubled without an increase of weight, but it was not enough. The motor boat *Antoinette* then held all records for her force, 80 horsepower, and was the lightest motor in existence. I said to Levavasseur:

"Why did you make such a light motor for a boat?"

"It is a light motor," replied Levavasseur, "but I did not intend it for a boat; I wanted to put it on an aeroplane."

"How did that happen? Nobody seemed to know anything about it."

"Nobody would buy an aeroplane, so I put the aeroplane motor in a boat which people would buy."

"How did you get it so light?"

"Simply by employing aluminum everywhere where the metal had no efforts to support. I made numerous experiments in physics and was able to reduce every piece to the minimum while still keeping a good margin of safety. My cylinders were ground inside and out to get the desired dimensions and were equipped with a brass water jacket. Finally, instead of eight cylinders, I used sixteen or even thirty-two."

"You reduce weight by increasing the number of cylinders?"

"Certainly; the lineal speed of a piston cannot exceed eight meters a second, you know that. The power of a motor only increases according to the square of its dimensions, while the weight increases according to the cube. It is better to have a number of small cylinders than one big one. I have no vibration and I have no need of a flywheel. Then, as I have always two cylinders under pressure, I can start by switching on the current. Won't that do for your aeroplane?"

"That will be fine," I replied. "When the wind is favorable I can cut out my motor, sail through the air, economize gasoline, and start up again without cranking."

"Why, nobody has done that yet on a steerable balloon," said Levavasseur.

"Mine isn't a steerable balloon; it's an aeroplane."

"Then with my motor you can go astern without any increase in weight, simply by shifting the camshaft."

"That is an old dodge," I replied.

"Not so old; I have got a German patent on it, and German patents are not easy to get."

"What about the carbureter?"

"I have abolished the carbureter. Experiments have shown that with a polycylindrical motor it is impossible to prevent one of the cylinders taking all the fuel. I feed the cylinder by means of special piping and a pump with whatever they need, gasoline, kerosene, hydrogen. Steerable balloons need not waste their gas; they can use it in the motor."

"Leave the balloons alone; tell me what you will do about ignition."

"I shall have a coil."

"Not a magneto?"

"No. First of all, it is too heavy; then with eight cylinders there is not enough time to fire all of them. I should have them all firing at the same time."

I was charmed with the prospect of obtaining the motor I wanted for my aeroplane and rushed off to my superior officer's bureau at Chalais and cried:

"Sir, I have found the motor I want."

"Eh?"

"Yes, sir; I must buy it at once."

"You are in a hurry; let us look at it first and see if it does give 24 horsepower for two kilograms."

"But, sir, I cannot bring it; it is not begun yet."

"Ferber, you are mad. Do you want me to buy it with my eyes shut? Suppose it is too heavy."

"But, sir, that does not matter. It is lighter than any of the others."

"My good fellow, you are completely mad. I shall not allow the Government to have anything to do with such an affair. You can go."

There was nothing to be got from the State, so I gave the order myself. I ought to have had the first engine; I am getting the last, after everybody else. It is my fault for ordering a special motor instead of taking the standard type. Santos-Dumont came along, tried a "24" immediately, found it insufficient, gave an order for a "50" and is now waiting for a "100."

I got my motor, built my aeroplane and had all ready last November. Then orders came to have the Government steerable balloon *Lebaudy* ready for sending to the Eastern frontier. The order was executed, my poor machine being left out of doors for a few nights. There was a heavy storm, the balloon could not start, of course, and my machine was destroyed. Of course, I feel mad against that steerable. But I don't care; they will soon get their last kick. I am going to start again—in another place.

Features of the Antoinette 16-cylinder 100-horsepower motor are, bore and stroke 4.1 inches, weight 220 pounds, length over all 50 inches, width 24 inches, height 19 inches, revolutions 1,400 per minute.

SKY DOINGS OF THE CLOUD BRIGADE.

Alan R. Hawley, of the Aero Club of America, and A. N. Chandler, president of the Aero Club of Philadelphia, had a successful balloon trip from Philadelphia to the neighborhood of Atlantic City Saturday last. The balloon, the *Initial*, was inflated at the Point Breeze gas works, and went away without a hitch. At one time the balloon rose to a height of 7,000 feet, due to suddenly passing into the full rays of the sun, after having thrown ballast overboard. After a little difficulty in hooking the anchor, the sky pilots were pulled up by a friendly tree. Mr. Hawley scrambled down the rope and secured the balloon.

Santos-Dumont has been unable to do much outside work in Paris owing to the boisterous March wind. A recent little preliminary canter over the Saint-Cyr drill ground, a quiet run to see that all was in order, and not an attempt to fly, resulted in one of the propellers being snapped off.

M. Alfred Le Blanc and Mr. Mix had a thousand-kilometer flight in the balloon *Limousine* last Sunday evening. Leaving Paris at 6 o'clock, they landed the next evening in the Isle of Rugen, Germany. The outward journey, including all expenses, cost \$50; the return trip by rail, however, called for an expenditure of \$100.

James Gordon Bennett has sent to the Aero Club of France a magnificent souvenir of the first international balloon race held from Paris last year. The gift consists of a silver plate made by Aucoc, the famous Parisian silversmith, representing the cup in the center of a decorative design. The Aero Club of America will receive a similar souvenir.

KEROSENE AUTO BOAT FOR PILOT WORK.

PARIS, March 19.—Launching ceremonies and motor boat trial trips are daily occurrences now on the reaches of the Seine, and will continue until the two special trains leave the Gare de Lyon with their load of motor boats for Monaco. This week the Société des Vedettes Automobiles invited a party of press men to Juvisy, a few miles out of the city, to witness the trial runs of

INITIAL TRIP OF FRENCH PILOT MOTOR BOAT.

their new automobile pilot boat. This company is making a specialty of the construction of sea-going automobile craft known as vedettes, for use as scout boats in the navy, and for various service around the coast, where speed and prompt service are required. *Pilot I.*, which took the water to-day, has been specially constructed for pilot communication with incoming and outgoing vessels. She is a stoutly built craft, capable of facing a heavy sea. Her length is 30 feet over all, the hull is built entirely of four-millimeter steel, and is completely decked over. The deck cabin is sufficiently high for a person to stand upright and is only 40 inches above the deck level.

The motive power is a three-cylinder 25-horsepower Mietz & Weiss kerosene motor of the type which recently gained second

prize in a competition organized by the French naval authorities. Twelve minutes only are required to start the motor and obtain the maximum speed of 600 revolutions per minute. The boat averages eight miles an hour in open water, a speed quite sufficient for the work she will be called upon to perform. *Pilot I.* will take part in the Monaco meeting. In our illustration showing her at work on the Seine, Comte Recopé is standing forward against the pilot house and amidships is Henry Kapferer, the aeroplaneist.

NINE DISTINCT TYPES OF AEROPLANE.

PARIS, March 18.—According to *Omnia*, there are nine distinct types of aeroplanes actually in existence or under construction which can lay claim to serious attention. Without any attempt to place them in order of merit, they are:

1. Santo-Dumont's new aeroplane, consisting of six cells, with a bearing surface formed of thin mahogany in place of the varnished cotton used in the *14 Bis*. Width of wings is 24 inches, total bearing surface 13 square meters, and reduction of weight on the previous model 66 pounds. Motor, 50-horsepower Antoinette eight-cylinder, to be replaced by 100-horsepower sixteen-cylinder Antoinette weighing 220 pounds, under construction.
2. Bleriot aeroplane of the monoplane type, bearing surface 15 square meters, weight 550 pounds, motor 20-24-horsepower. M. Bleriot is now completing another aeroplane fitted with a 50-horsepower sixteen-cylinder engine.
3. Delagrange cellular aeroplane, bearing surface 60 square meters, weight 638 pounds, motor 50-horsepower Antoinette. Has only made one trial trip, which revealed fragile construction.
4. Vuia aeroplane, area 12 square meters, 12-horsepower carbonic acid motor, designed by Léon Serpollet.
5. Kapferer cellular aeroplane, bearing surface 60 square meters, weight 616 pounds, motor 20-horsepower Buchet.
6. Count de la Vaulx aeroplane, with a single bearing surface, built on the model of a flying bird, in the rear two propellers turning inversely, driven by a 50-horsepower motor.
7. Ignaz and Vels aeroplane, with a single curved bearing surface, having much resemblance to a maple leaf. There is no rudder. Motor 20-24 Antoinette.
8. Vaniman aeroplane, now under construction, with a single bearing surface, to be propelled by a 70-80-horsepower motor.
9. Rebiffoff and Chevalier de Corvin aeroplane, designated by the inventor an orthoplane, motor 70-80 horsepower.

OUTLINE SKETCHES OF A NUMBER OF NEW EUROPEAN AEROPLANES.

1. Bleriot Aeroplane: a, rudder; b, 24-horsepower motor. 2. Comte de la Vaulx Aeroplane: two propellers and 50-horsepower Antoinette motor. 3. Santos-Dumont Aeroplane, latest model: a, framework; b, Antoinette 50-horsepower motor; c, wings; d, propeller mounted direct on motor shaft. 4. Ignaz Etrich & Wels Aeroplane shown in perspective and from above: a, a, propellers; b, 24-horsepower Antoinette motor. 5. Delagrange Aeroplane: a, b, cellular bearing surfaces; c, rudder; d, 50-horsepower Antoinette motor.

LIMITS OF TOLERANCE IN AUTOMOBILE PARTS

By THOS. J. FAY, E.E.

AUTOMOBILE construction, to a far greater extent than machining work in general, requires that the duplication of parts be in fact rather than in theory, the true situation in relation to this matter being, more or less, one handled rather glibly by the able advertising manager, or, to more elegantly put it, "The Publication Department," in many establishments noted for the quality of their products. Unqualified, the above statements sound harsh, and would be pronounced of exaggerated breadth by mostly every maker of cars, for of all none would admit for one moment that parts are always in duplicate.

On the other hand, what is called the duplication of parts is another matter; what most makers really mean is that the cars are crystallized and the parts are produced by means of jigs, templates and gages, in so far as the exigencies of the situation would demand or warrant. In other words, if a part can be produced by means of a jig, a fixed tool or a process, at less cost than the same part could be produced by the ordinary process, as in a jobbing shop for illustration, of course resort is had to the cheapening process, and fortunately uniformity to a greater or less extent follows the process.

To attack the matter in hand from still another point of view would be to say certain parts can be produced to any desired degree of accuracy on a lathe in conjunction with a grinder, but the process would be slow in comparison, if, perchance, the parts in question could be produced on an automatic screw machine or on a semi-automatic turret lathe, or by any other multiple tool process, more or less automatic, by means of which quantity naturally takes precedence, or less quantity by the more laborious but not less accurate engine lathe.

Absolute Accuracy Impractical.

As a matter of fact, quick work on automatic tools is not, nor can it be, absolutely accurate; moreover, there is no good reason why absolute accuracy should be attempted, but the sum of the inaccuracies, even if arranged in algebraic order, do not of necessity equal zero, while the small inaccuracies as between connecting parts may be of such moment as to abort fitting, by a man of ordinary skill, without resort to tools such as lathes, mills or whatever would serve to wipe out differences in fitting parts.

The duplication of parts, then, is rarely the duplication promised by the "Publication Department," for, according to the flowing language of the persuading staff, a part, if replaced by a new part, will be replaced without any trouble at all; in fact, the new part will fall right into place and serve perfectly. This is obviously a wrong view to take, nor can this view be foisted on an autoist after he has used up his first car, for ere one car is ready to sell for "as good as new" the owner will have secured good and wholesome views of just what a duplicate part really does mean. Why should parts go together without any "fitting" at all? Drawings are usually turned out showing that a 2-inch shaft, for illustration, is to go into a 2-inch hole. Some say it is possible, more claim it is not; but the writer claims that the owner of a car will be much engaged if any attempt is made to solve the problem. In shops in general, fitting allowances are left to the foreman or the workman, but in a large shop there are a good many workmen and several foremen, hence it follows that all allowances are not from the same point of view or on the same basis, because all men do not think alike, nor is there any rational ground for expecting any such a phenomenon.

In an automobile there are a goodly number of situations and several conditions to satisfy, hence allowances for fitting must take into account the respective conditions for the respective places, else fitting will be a dire undertaking, with every chance of a loose fit where a tight fit would be proper or a drive fit in place of a loose fit, and so on. Just how any set of workmen,

however qualified to do good work, can satisfy so great a variety of conditions without a preconceived plan, is past all conception. To have parts come so accurate as to require no fitting work at all is extremely difficult, and demands that a system of allowances be devised and used. A system of allowances, or, as the matter is generally referred to, "limits of tolerance," are not new, nor do all shops disregard the matter, but the point is made that even shops that do take into account a prearranged system or set of limits to go by fall short in that the system is rarely worked out complete, or if it is worked out it is not followed out, mainly because draftsmen leave it to foremen and foremen pass it up to workmen, while the latter, accustomed as they are to doing things, make the best of the situation and the allowances as in their judgment *would seem to serve the end*. In many cases they are quite right, but it is too much to expect to be able to

DIAMETER OF SHAFT

buy all the cardinal virtues for \$15 per week, and the risk of failure is ever present in this class of mechanical work.

System Necessary to Meet Requirements.

The only way by means of which duplicate parts can be produced with sufficient accuracy to enable one to fit a new part—that is, a replacement—is if the limits of tolerance are worked out for every situation and the system is followed up completely and under the direct supervision of some one man skilled in the process of making allowances. That is, in a shop big enough to talk about. A system of this sort is based on inaccuracy; in other words, the system allows for errors and allows as much error for each case as the situation will permit, but the system fixes not only the magnitude but the direction of errors, and by so doing enables machinists to come within a fitting range, because *the errors are not added one to the other*.

A system, for illustration, takes into account the oil film that must be allowed for in places using oil, and disregards the pressure of oil, if oil is not to be present. Such a system allows for varying diameters of parts to be fitted and the ease with which accuracy can be realized in some places as against the

TABLE II (METRIC).—Serviceable for fits of members with a fixed relation, but not for journals, considering parallel work. In these cases the bore of the holes should be within .0125 inch below the drawing size given, and the shaft or other part should change the amounts of these allowances above or below the diameter for the hole, as the case may be, considering the purpose.

difficulty involved in attaining accuracy in other places. Taper fits are resorted to when possible on the ground that a taper fit can always be counted on for a good fit, but unfortunately taper fits cannot be taken advantage of in many places. Indeed, the idea with an allowance system is to provide a suitable allowance for every character of a fit, in every location, so that nothing will be left to chance or the individual judgment of abstract man.

It is all right enough to take advantage of the knowledge possessed by men of skill and experience, but that knowledge should be reduced to a concrete form and its use should be confined to a legitimate zone on the ground that changing the conditions must result in changes all along the line. Some years ago the writer, as "executive engineer" of the C. W. Hunt Company, used a set of allowances or tubular limits of tolerance devised by Mr. Hunt

DIAMETER OF SHAFT	BORE OF HOLE GREATER THAN DIAMETER OF SHAFT

TABLE III (ENGLISH).—Serviceable for bearings and similar work. In all cases while figures given are for bore of hole greater than diameter of shaft, the bores should be within .0005 inch of standard dimension given, and the shaft or part to fit the hole should have the allowance here given, below the standard dimension given on drawing.

and found the allowances quite in keeping with the requirements. Later on, when the automobile question demanded better attention, the writer revised the tubular values from time to time and broadened the system in all ways consistent with experience and new conditions. The values were also reduced to the metric system under stress of circumstances and additional tables were compiled, with a view of covering the whole subject.

Metric Measurements an Aid.

The question of the extent to which the metric system will, in future, be employed in America is one for the future to settle, but the writer has adopted the metric system and is using it in his regular practice to very good advantage, and it is believed an actual gain in time, as well as a reduction of possible errors, can be directly traced to the use of the metric system.

Before proceeding to employ the metric system, one of the most important matters was to fix up the tables of allowances in metric increments, because numerous workmen were not able to think in metric values, so to speak. This matter was not found to be as troublesome as might be supposed, because in automobile work a great number of the artisans are from abroad and came here as an adjunct to foreign automobiles.

BORE OF HOLE GREATER THAN DIAMETER OF SHAFT

DIA. OF SHAFT	CLOSE FIT	FREE FIT	LOOSE FIT	NOMINAL FIT
25	.075 To .125	.2 To .275	.275 To .7	0 To .050

TABLE IV (METRIC).—Serviceable for bearings and other similar work. In all cases, while figures given are for bore of hole greater than diameter of shaft, the bore should be within .0125 inch of standard dimension given, and the shaft or part to fit the hole should have the allowance here given, below the standard dimensions given on drawing.

In any case it is well to have the limits of tolerance both in the English and metric measure, because the large number of foreign cars found in America are in metric measure, and in repairing them success depends, to some extent, at any rate, upon the use of the metric system. This point is not as broad as one might suppose, for, as can be reasoned, a repair is only made if a part wears, and just as likely as not the wear of the adjacent connecting part will be enough to make it possible to employ English units without detriment to the fit of the replacement to the connecting part.

As may be conjectured, the writer is not aiming to bolster up the metric or any other system, for in all truth the quality of a product is in the main independent of the units of measure, and one is perfectly free to use the one or the other of the systems; indeed, to be able to do so, the tables of allowances were broadened and extended, as before stated. The allowances differ in some ways from allowances as published by some concerns, and for the matter of that the writer knows of some published allowances that, if followed, spell failure, because they are neither right in theory nor adjusted to the needs of the situation.

Take a shrink fit, for illustration. If the allowance for fit is excessive, the inner member will collapse or the exterior member will split, or both members deform. This is an every-day occurrence and it is due to a lack of knowledge of the allowance that should be made for shrink fits. It is quite easy to strain the method beyond the elastic limit. In many places the fit can be anything but accurate and the result may not be impaired; moreover, a great many dimensions of parts are quite independent of any fit at all, hence to machine to dimensions closely would be a waste of time and money, to no avail. The system of allowances, then, is based on the assumption that no part can be machined to "neat" size and the principle of "error" is admitted. The real question, then, is one involving an allowable error, and the tables tell how much of an error will be permissible, but the error must be in a certain defined place, as, for illustration, in a "drive" fit the "bore" should be a "reamed" size, within, say, .005 of an inch below size. The shaft should be over size by some amount, depending upon the diameter of the shaft. Take, for illustration, a 4-inch shaft; for a drive fit

Table V gives the limits of tolerance for taper fits, taking into account tapers, viz., 3-16 of an inch, 3-8 of an inch, 3-4 of an inch and 1-2 inches to 1 foot. These tapers are enough to cover all possible cases in automobile work on a basis as follows:

DIAMETER OF HOLE TO BE LESS THAN SHAFT BY

DIAM. OF PART	PRESS FIT	DRIVE FIT	HAND FIT
25	.125 To .150	.0125 To .025	.0025 To .025

12"	.016 To .017	.006 To .007	.

TABLE VI (METRIC).—For 1 to 64 taper fits of parts. In every case make the male member within .0125 inch above the standard size given. For 0 to 32 taper, divide above values by 2. For 1 to 16 taper, divide above values by 4. For 1 to 8 taper, divide above values by 8.

Three-sixteenths of an inch to 1 foot, for parts not to be taken apart, unless when broken or worn out, as flywheels on crankshafts and like cases.

Three-eighths of an inch to 1 foot, for parts likely to have to be pulled apart, but to be securely held, as sprockets on jackshafts and like work.

Three-fourths of an inch to 1 foot, for parts to be taken or pulled apart at intervals.

One and one-half inches to 1 foot, special cases, but not much used.

Table VI represents the same class of work, using the metric instead of the English system. In this case that taper for

TABLE V (ENGLISH).—For 3-16 in. to 1 foot taper fits of parts. In every case make the male member within .0005 inch above the standard size given.

For 3/8 in. to 1 foot, divide above values by 2.
For 1/2 in. to 1 foot, divide above values by 4.
For 1 1/2 in. to 1 foot, divide above values by 8.

the shaft should be from .002 of an inch to .003 of an inch above size. This allows .001 of an inch to go on and a plus allowance great enough to guarantee a "drive" fit, even though the bore be slightly off, but as a guarantee against trouble from this source the bore should be slightly under, as provided.

Table I gives the limits of tolerance for press, drive, hand and nominal fits, using English measurements, and considering what has been said the table should be clear enough without further explanation. It will be understood that by "diameter" is meant the diameter of any given part nearest to the tabular diameters.

Table II gives the limits of tolerance under the same conditions as would obtain for Table I using the metric system instead of the English system of measurements.

Table III gives the limits of tolerance under still another set of conditions. In this case the "bore" is considered as within .0005 of an inch of the standard, making it possible to use standard reamers and the allowances are minus values on the shaft, taking into account close, free, loose and nominal fits.

Table IV gives the limits of tolerance under the same conditions as would obtain for Table III, using the metric system instead of the English system of measure.

TABLE VIII (METRIC).

the equivalent of 3-16 of an inch to 1 foot is set down as 1 to 64, hence the other tapers would be 1 to 32, 1 to 16 and 1 to 8, respectively, for 3-8 of an inch, 3-4 of an inch and 1-2 inches to the foot, respectively.

Table VII takes into account the limits of tolerance of dimensions and parts not required to be definite, but in which an allowance can be made such as will enable machinists to easily and quickly come down to a size close enough for all practical purposes.

FIG. 1.—Method of noting on section.

Table VIII is the metric equivalent of Table VII.

These tables—VII or VIII, as the case may be—are to be used to go by in all cases in which specific limits of tolerance are not given on the drawings for each important dimensional value.

The method of noting limits of tolerance on drawings is one worthy of discussion. Draftsmen in making drawings put down "neat" dimensions, making no allowance at all, as, for illustration,

a 2-inch shaft is shown to go into a 2-inch hole. The person assigned to make allowances then takes the drawings and puts down the allowances as "plus," "minus," or "plus and minus" values in juxtaposition to the dimensional values to be influenced, as follows: (A) 2" +.002, if the dimension is to be .002 more than 2"; or (B) -.002 where the reverse; and where permissible to have fit come between either of these limits, (C) 2" +.002.

Advantages of Such a System.

The objects in thus fixing the allowances are threefold, viz.: (a) In order that draftsmen will not be required to waste time making allowances, thus enabling them to put down "neat" dimensions. (b) In order that one man skilled in the practice can go over the drawings and append the allowances. (c) In order that machinists will know at sight not only that allowances have to be made, but the magnitudes of allowances as well. Unless machinists can see that fits are provided for, they, by virtue of their training, are bound to give the matter further attention, and they will best be able to see at a glance if all allowances are put down in the manner as above set forth.

The drawings Figs. 1 and 2 show just how allowances are noted, remembering that the absence of allowances authorizes machinists to use the values in Table VII or VIII, English or metric, as the case may be.

In conclusion, there is one further point of magnitude sufficient to warrant discussion, viz., the taper as given, 3-16 of an inch to the foot, has an especial value in that an advance of one member into the other of 1-16 inch is at the expense of a difference in diameter of 0.001 inch nearly. It follows that a "taper play," if marked off by rings 1-16 inch apart, serves as a source of definite information to the machinist. Without this plug gage, measuring a taper hole becomes a matter of no small concern.

A WORD FOR BELT TRANSMISSION.

Automobile engineers have been largely recruited from the ranks of bicycle makers, and it is only in recent years that true engineers have given any attention to motor car work, says *The English Mechanic*. Hence, original errors have been to a large extent perpetuated, though by the use of improved material and better workmanship, such crude ideas as the sliding of gear wheels into mesh while revolving have to some extent turned out better than one would have expected. There is no reason why a belt should not be as successful in transmitting power on a motor car as it is in driving the machine tools used in the construction of the cars. There are plenty of belts made that will run equally well when wet as when dry, and we can always protect the belt from actual contact with mud and water, leaving only atmospheric conditions to contend with. Then as regards economy of first cost and upkeep, the belt is far ahead of gearing. Again, who could repair a broken gear when on the road, even if a spare wheel be at hand? In most designs it means half a day's work to get the old wheel out and another half-day to replace the parts and get the car into running order again. Anyone could put a new belt on, and a spare is easily carried. The whole reason for the apparent failure of belt-driving is due to the use of belts too narrow for the power, and too small pulleys placed too close together. Given a decent width of belt, pulleys as large as the space allows, and shafts as far apart as possible, and the result will be a car of simple design, cheap to make and maintain, easy to repair, and more silent than any gear-driven vehicle. I would go further than Mr. Smith by eliminating the gears he mentions, by having fast and loose pulleys only. Surely this device has been well enough tested and exploited in the many engineering and other works all over the world for us to have confidence in it. Mr. Smith's specification does not want much alteration; do away with the gears and use fast and loose pulleys, is my amendment. Differential gear we must have; but this is not likely to give trouble, or make noise, if well designed. It will be interesting to have the views of readers on the subject, and probably some valuable suggestions will result.

WHAT HAPPENS TO OVER-STRAINED METAL.

Will the time ever come when we shall know what has really happened to a piece of over-strained material? asks the *American Machinist*. It has been usual to suppose that its particles were already partially severed—pulled apart by tension so that they were in a sense past repair. But recent investigations appear to show that this is not the case, but that both for iron and for steel the over-strained state gradually disappears, and ultimately an over-strained piece gets near to its original condition. A piece of semi-mild steel strained at its yield point of 38 tons until it took a permanent set of 0.13 in. in 4 in., regained a lot in two days, progressed for two weeks and was entirely perfected by heating to 200 deg. C., though a few minutes at 100 deg. C. would have served nearly equally well. Other metals recover from over-strain with rest, and more quickly by the application of moderate heat, and both aluminum and copper have been tested. Aluminum bronze recovers very slowly with time, but rapidly with moderate heat treatment.

FIG. 2.—How allowances are noted on plan.

AUTOS FOR THE HEART OF DARKEST AFRICA.

The almost uncivilized tribes of Southern Nigeria are about to be introduced to the most recent development of modern civilization, says *The Egyptian News*. The first motor-car to be used in the Protectorate is now on its way, a smart touring vehicle built to the order of the High Commissioner, Sir Walter Egerton, for his own private use. Hitherto road surfaces in Nigeria have been so bad, generally speaking, as to render vehicular traffic of the motor type impracticable, but new roads are being made and railways are springing up in all directions. With facilities for petrol and "spares," no doubt the motor-car will meet in Southern Nigeria with a modicum of that success which has attended its introduction into other comparatively unknown countries.

WHAT AUTO INVENTORS ARE DOING ABROAD

AS fuel consumption is to play an important part in the speed contests to be held during the present season in France, the driver or builder who by some clever artifice is able to provide his car with an additional five or ten litres of the precious *essence* will have an incalculable advantage. To quote a late issue of *Omnia*, from which the present is an extract, "he will be able to give his motor a stomach that much bigger,

them, whether it be gasoline, alcohol, etc. As soon as a tank has been weighed, it will be replaced on the car, and will be supplied immediately after with the quantity of fuel necessary for the entire test. The accompanying line sketches illustrate the means provided to prevent any of the contestants using more fuel than the regulations provide him with. Fig. 1 shows the application of a lead seal to a gasoline filter in the supply line; Fig. 2, the seal as applied to the carbureter inlet; Fig. 3, manner of doing the same to a stop-cock, while Figs. 4 and 5 illustrate gravity and pressure supply openings to the tanks.

DEVICES ADOPTED TO PREVENT FRAUD IN THE GRAND PRIX.

FIG. 1.—Method of sealing filter. FIG. 2.—How stopcocks will be sealed. FIG. 3.—Seal on carbureter intake. FIGS. 4-5.—Seals on Tank Fillers.

and with correspondingly greater power." In consequence the Commission Sportive of the A. C. F. has called upon the Commission Technique to formulate plans for the prevention of any possible means of fraud in this direction, and the latter has submitted the devices shown in the accompanying illustrations as effective preventives of the introduction of any supplementary supply of fuel during the course of the race.

(1) All tanks will be provided with a single filling vent of the type already adopted by the Commission Technique and its use will be compulsory on all vehicles. It will be made with a free air vent for gravity fed cars and an air-tight cap for pressure fed systems.

(2) Also of a special design of tank outlet, as per the model already adopted. Each carbureter will be provided with a special type of feed union, and where a carbureter is equipped with a drain cock, it must be disposed in such a manner as to permit of the application of a lead seal. The supply pipe from the tank to the carbureter may be equipped with a filter, but such filter must also be arranged so that all its openings may be sealed. Gravity tanks must not have any other orifice than those above indicated, *i.e.*, filling and feed. Pressure tanks must have but one orifice for the introduction of gas so arranged as to be sealed. Tanks must be made so as to be readily dismantled and must be presented to the commissioners specially appointed to examine them on the eve of the test.

The weight of the tank will be taken both before and after the race, and the commission reserves the right to take apart any tank after the completion of the test. Cars whose tanks do not comply with the foregoing conditions will not be permitted to participate. Entrants may employ whichever fuel best suits

Dismountable Rims Still to the Fore.

Though there has not been much said of the dismountable rim during the past few months, it is evident that attention in this direction has not been lacking. In tackling this problem American inventors have one and all tried to discard the standard clincher type of tire entirely, and many of the devices evolved are not only ingenious, but very practical. Abroad, those who are devoting attention to the subject appear to be working very largely with the clincher tire as a basis. The Shrewsbury and Challiner rim, of which illustrations are shown here, is another instance of this that has recently come to light in England. It consists of a composite rim, says the *Autocar*, with a shallow wooden felloe, surmounted by a flanged steel rim. The flanges on the latter are very deep, so as to compensate for the shallowness of the wooden felloe, giving the wheel much the appearance of one that is solid. As shown, one of the flanges is detachable, so that upon its removal the tire may be drawn off bodily on its own rim. In Fig. 6 the rim is shown dismantled, giving an idea of its components, and also picturing the wooden blocks placed at intervals round the periphery of the felloe to serve as supports between the wheel proper and the rim of the tire which rests upon them. Passing through each of these blocks is a bolt corresponding to a hole in the detachable flange, and securing it in position by nuts when it is on. Both the tire and its rim are of the standard clincher type with the exception of the security bolts, the stems of which are made shorter, though the valve stem is left unaltered, this being made the starting point when placing a tire and the finishing point when removing. The sectional view clearly illustrates the disposition of the various parts when the tire is in place,

FIG. 6.—Details of the new English dismountable rim.

with the exception of the bolts, which pass transversely through the solid flange, wood block and detachable flange, as already mentioned.

Comparative Strength of Wire and Wood Wheels.

Though it has long been generally recognized that, weight for weight, the wire wheel is greatly the superior of its wooden rival where strength is concerned, just how much more it was

FIG. 7.—Position of wheel in testing machine.

capable of standing than the latter has never been set forth in the shape of comparative data, so that the results of a comprehensive series of tests made in England and brought to light by the *Autocar* are of considerable interest. The wheels are tested in a Denison 6,000 pound tensile testing machine specially equipped for this purpose. The wheel is fitted to a spindle, which is connected to the bed of the machine and rigidly supported at both ends, so that in measuring the deflections of the wheels due to the varying pulls the "give" of the spindle will be eliminated. A block of wood is fitted into the rim and round this a sort of stirrup, the whole apparatus being so proportioned that the pull comes on the wheel at the equivalent of the road line and not at the rim. It will also be noted that the pull is in the same direction as the axis of the wheel, as denoted by the arrow shown alongside the tension strap in the illustration showing the wheel on the machine under test. Fig. 7.

In Fig. 8 a diagram is shown on which curves of the comparative strengths of the two types of wheels have been plotted, the deflection in inches being measured on the horizontal and the pull in pounds on the vertical line. All the wheels tested were quite new, and, owing to the greater rate of deterioration to which wood is subject, it would be necessary to provide a higher factor of safety in the case of the latter to make it equally safe as the wirewheel throughout its existence. This is apparently not done, as none of the heaviest wooden wheels proved to be within five per cent. of the strength of the weakest wire wheels, despite the great difference in weight.

The curves plotted on the diagram in Fig. 9 are based on the same series of experiments as those in Fig. 8, but they have been corrected for weight by dividing the pull by the weight of the wheel. Consequently the vertical measurements to any point on the curve represent the number of times its own weight that is required to cause the wheel in question to deflect an amount represented by the horizontal distance to the same point. For example, the wire wheel deflects 1.48 inch

with a load of 185 times its own weight, and the wooden wheel D deflects 3.9 inch with only 63 times its own weight. This diagram further supplies the data necessary for the construction of a wheel that will be the strongest for a given weight. The wire wheels used were made by the Rudge-Whitworth Company, the well-known English makers of bicycles. Of course, there are insuperable objections to the use of the wire wheel on pleasure cars that are so patent as to hardly call for comment, but the data show its great value for racing purposes.

Preparations for Madrid's First Show.

Up to within the past year or two Spain's progress toward the adoption of the most modern style of locomotion was somewhat on a par with that of the frozen dominions of the Czar. The only Spanish highways are the *carreteros*, or cart roads, that have served from time immemorial as means of communication between the cities, and which are about in the same condition today as they were when Don Quixote rode over them in search of adventure. Few tourists venture over the French border in this direction and those who did found points of supply so few and far between, and the reception accorded them so hostile, that they were not anxious to repeat the experiment. But Spanish royalty has changed all that; it has put such a firm seal of approval on the automobile and everything pertaining to it that there is no alternative left to the population but to do likewise. Hence Spain is shortly to have its first automobile show, and, like all first attempts, it will include exhibits of bicycles and other miscellaneous features somewhat alien to the auto.

The exhibition will be opened on the 4th of May and continue

FIG. 9.—Corrected curves showing deflection in inches.

for fifteen days, or until May 19. As is natural under the circumstances, the great majority of the exhibits will be by French makers, though in the preliminary list already published there appear a few scattering representatives of the Teutonic and Italian industries. Every inducement is being held out, the Government having accorded the privilege of free entry for all exhibits that are to be returned within three months.

Prominent among the exhibits will be the product of Spain's first automobile factory, La Hispano-Suiza. Some of the well-known Continental makes that will be staged are the Panhard, Dietrich, Berliet, Benz, Delahaye, Brillie and Bianchi. Your true Spaniard moves leisurely, as may be surmised from the following information set forth in the official bulletin of the coming event, and which will be found to contrast somewhat sharply with similar things here, where forty-eight to sixty hours usually represent the maximum permitted the management to install the decorations and the exhibits. Compared with this, exhibitors at the Madrid show will have from April 16 to April 30 to decorate their stands and put the cars in place. On May 1 there will be a meeting of the commission to dispose of stands not occupied up to that date; all to be ready by May 2. Here, twenty-four hours are usually given in which to dismantle the show; exhibitors at Madrid will have to May 29, or eleven days.

FIG. 8.—Comparative deflection of wire and wood wheels.

PAST AND FUTURE OF POWER TRACTION ON ROADS*

BY THE RIGHT HON. SIR. JOHN H. A. MACDONALD, K.C.M.G.

THE marked difference between the people of this country and the people descended from us in the United States is that, whenever an American is presented with a new idea relating to some practical purpose, his whole energy is concentrated on finding out whether he can make it do, and on endeavoring to improve upon it, to make it do still better. We, on the other hand, have a constitutional tendency to try to find out how it will not do, to treat it with suspicion as a new-fangled useless thing, and on the slightest hitch, probably caused by our own want of skill in handling it, to cast it aside as useless. I remember, when a boy, seeing in the first great exhibition, in 1851, two American reaping machines, the first London had ever seen, and which immediately set the fashion of mechanical reaping all over the country. The fact is that the practical part of the machines was not new. A reaper on exactly the same principle was invented by a Forfarshire clergyman so far back as 1822, and was then in use, and had been in successful use for twenty-nine years before Hussey and McCormick were ever heard of. But no one ever thought of following this Forfarshire farmer's example until the reaper came to us as a novel Yankee notion.

Keeping in view this tendency to negative new ideas—to spend energy in finding reasons why they should not succeed rather than to strive to make them successful—it is truly a thing most astonishing that the road power vehicle has made the extraordinary advance which we have seen in the last ten years. The fact that it has done so demonstrates its transcendent potentiality as a practical mode of locomotion. It is true that a fair trial was also refused to it seventy years ago, but this was not brought about by adverse scientific opinion. No scientist spoke against it, and many enthusiastically supported it. The reason why we have not had power vehicles on the road during the six last decades of the nineteenth century is not to be found either in scientific rejection nor in practical demonstration of failure. It stands recorded on the books of Parliament that power traction was at that time a practical success, and the same Blue-book tells of the efforts made to crush it out, which were only too successful. The parliamentary power of the railway interests, and of the peers and squires and farmers, was ruthlessly applied to destroy the new industry from pure selfishness in the former class and crass stupidity in the latter. The railway interest saw in it a dangerous rival, the land interest failed to see its certain benefits to country districts. Short-sighted greed killed power traction by iniquitous tolls and deliberate road outrages, and it was not heard of again until in the early sixties. Thomson drove by steam the first rubber-tired wagon and the first steam rubber-tired omnibus for a short time in the streets of Edinburgh, acting illegally, and, therefore, was very soon made to stop his experiments.

All this makes it the more astonishing that in ten short years since the Act of Parliament which gave permission to vehicles for ordinary purposes moved by mechanical power to use the road, such strides in advance should have been made.

I do not believe that when the little string of cars started for the first joint run to Brighton to celebrate Emancipation Day there was anyone in the procession into whose mind it entered for a moment that that tiny nucleus had in it the germ of the flourishing, well-rooted and fast-growing plant of to-day. Without disparaging that gallant effort of the few plucky pioneers to celebrate the Emancipation Act, there can be no doubt that the 1,000 miles trial of 1900 was the event which first gave a real impetus to motor traction in this country. The Brighton run was the flashing out of the enthusiasm of the few, the 1,000 miles tour was the kindling of the real fire never again to cease glowing—that fire of confident enthusiasm which is irre-

*Extract from paper read before the Automobile Club of Great Britain and Ireland.

sistible, which then began to flame up vigorously, and is steadily burning its way through the thickets of selfish and prejudiced opposition, which have done their utmost to smother it out. Can anyone doubt that our fate would have been a sad one when Parliament took up the matter in 1903, had the demonstration of 1900 not convinced all but the hopelessly prejudiced that motor traction on roads was a practical and useful advance in locomotion, which, whatever its drawbacks might appear to be, must be accepted as an accomplished fact, and that reasonable regulation, and not repression, was the only statesmanlike course in dealing with it. Many things, of course, happened on that memorable journey which would not happen now. The cars were not—could not be—the steady-going, trustworthy carriages which we enjoy the use of now. There was much that was of the experimental stage about them all, and experience was limited. It was plain to be seen that the problem of convenient road traction by mechanical means was definitely solved, and that whatever ups and downs might take place in the future, progress to efficiency and to triumph over prejudice were assured. Whether any of us realized that the triumph would come so soon and be so complete I doubt. But this I think I may say for all of us who made the nineteen days round, that we did not feel from the first as if we were making an experiment. We knew that we were demonstrating the existence of a real and practical system of locomotion, the success of which was an accomplished fact, and the predominance of which was an ultimate certainty.

But great as was the success of the 1,000 mile trial, it may well be doubted whether the cars which took part in it had among them as many vehicles as could be counted on the fingers of one hand which would compare, in any reasonable degree, with the touring car of to-day, and there was not among them all one single carriage with a cover. A few had hoods for one seat, but that was all. On the other hand, many of them had excellent engines, of lasting quality. The car in which I rode was still doing work a short time ago, and may be doing good work still.

In order to gain an appreciation of the extent of the recent rapid speed of automobilism in this country, I have made it my practice for the last two years when I happened to be in town to take careful note of the number of power vehicles as compared with those drawn by horse haulage, and the result of many observations is to make it plain that enormous strides have been taken and are still being made from day to day. I shall give you some figures presently, but I wish first to point out that not only is the rapid increase of numbers a cause for wonder, but that something more wonderful has happened. I mean the rapid increase of cars which are built to take the place of the barouche, the landau and the brougham which were our *voitures de luxe* until lately. Whereas in 1900 all the automobiles were open pleasure vehicles, a very large proportion now are high-class carriages, which will compare for style and elegance of fitting with the best Laurie and Marners or Morgans of past days. Indeed, one has only to take a walk along Oxford street, or Bond street, or Longacre, to see the coach-builders who cater for what are called carriage people, and who a few years ago would have scouted the idea of allowing an autocal to be seen upon their premises, vieing with one another in display of motor carriages of all descriptions, the cars being placed in front, and the horse carriage relegated to the rear.

But a still more remarkable feature of the development of motor traffic has recently made itself manifest. For a long time it was the common belief that the motor vehicle was the toy of the wealthy sportsman, that its appearance upon the road was only the result of a temporary craze, and that very soon it would lose its attractions as a sport, and would cease to

make progress, and ultimately be relegated to special sporting tracks or die out altogether. It is only necessary to observe what is going on to see how absurd any such ideas are. It is becoming more and more clear every day during the last two years that the autocar is no longer the amusement carriage of the leisured, but is becoming the conveyance of the business man.

As regards the future, the business of the hour is not, as I think, the assisting of the trade to show the excellence of their wares or to organize competitions to show what the power vehicle can do as a fast vehicle. It is the commercial vehicle that requires most attention. The business vehicle is now beginning to make its way. It is significant that such a firm as Pickford, who owned the first steam road wagon more than 100 years ago, are doing a tonnage of 480 tons, that another firm is replacing 300 vans by motor vans, that their use by the postoffice is already increasing, and the fire brigade and ambulance services are being rapidly converted. The success of the commercial motor will do much to make the public—ever slow to accept change, however beneficial—begin to take power traction as a matter of course, and when it does this it is only a step further to its being recognized as a benefit. This is already the case as regards the motor omnibus. When the snow was on the ground one read in the newspapers paragraphs such as this, taken from a leading paper: "It will be interesting to see how a motor omnibus will behave when a frost or thaw sets in. There will without doubt be an increased number of casualties with lamp posts in London thoroughfares, that are on an incline"; and a picture, intended to be funny, was given of vehicles crashing into standards, smashing into shop windows, and colliding with one another all over the place. The few days which followed this prophecy disclosed the fact that while the electric tramcar and the horsed omnibus had often to give up the struggle against snow and frost, the motor omnibus went gayly and successfully through its work. It will be the same in other departments of commercial transport. The motor vehicle, both for pleasure, for traveling and for commerce, may now be left very much to work out its own way. The real work that is before us is, I suggest, in other directions. The motor for personal and mercantile purposes needs no further nursing. It can take care of itself. The work of the future seems to me to be a work of overcoming the forces which tend still to induce the legislator to think that he is serving the public good and pleasing the crowd by crippling and obstructing progress. Now, what are these forces? There are three, two from external sources and one from within. There is first the bitter and rabid opposition of that large class in this country to whom every change which shakes them out of their groove is intolerable, or, if not intolerable, distasteful. There is, second, the real provocation caused to the non-motorist by the dust on the road being disturbed, to his discomfort. There is, third, the enemy who, to our shame, is of ourselves—the inconsiderate and sometimes even black-guard motorist, and he is the very worst enemy we have.

Fast mail coaches were to ruin the country and cause physical breakdown. Railroad traveling was to destroy our nerves and cram our asylums, and shorten the average life, which has been going up for the last seventy years. The railway train was to deprive our children of sustenance by making the cows withhold their milk. Cycling was producing a haggard, mentally diseased look on our faces. Now we motorists in our turn are told that motoring is attacking our spines, ruining our nerves, breaking down our health, and hurrying us to the madhouse. Yet here we are, like the jackdaw of Rheims, we are under the curse, but strange to relate we are nothing worse.

Well, we may laugh at these extravagances, but they have their serious aspect. They tell of a deep-seated enmity to our cause, the more virulent, because unreasoning. It must be met as if it was serious, and resolutely combated by vigorous argument and refutation, and for this all who have the cause at heart should arm themselves with facts and illustrations and

press them in society on every occasion when it is discreet to do so. We must show that we are rationally serious, and not to be put down by strong adjectives or blatant prophecies.

The second point as regards the future is the dust question, which is of all the most important and the most dominating, because it is one as to which complaint is justified. Even when driving is considerate, the evil of dust is still not trivial, and when the road cad is about it is not only objectionable but intolerable. I have seen a car approach and go past without slackening speed in the least, thick clouds flying out right across the road, like the smoke from a double broadside of quick-firing guns, compelling every other vehicle to come to a dead stop for minutes, it being impossible to see at all. I have even seen this done by distinguished members of this club, in the exuberance of their salad days as motorists. I believe if they look back now they will be contrite. Such conduct to those on foot or wheel, and to residents on the road, is as unworthy of good sportsmanship as it would be to force horses at a gallop through a crowded market place.

But the dust is objectionable even where the driving is considerate. The old mail coach raised dust terribly, but the crowd of auto cars makes it worse. Therefore, there can be no doubt that the repression of dust is a great question of the hour. That the roads can be brought into a practically dustless condition is, I think, certain. Experiment has proved this conclusively. All must rejoice to know that this matter is being taken up by a special committee representing all classes of interests, and that the feeling is growing that Government care of the roads and Government aid are the true means of solution of the problem.

The last enemy with whom we have to contend is the most deadly enemy of all—the foe of our own household—the inconsiderate driver, to whom allusion has already been made in speaking of the dust question. The man who holds the crown of the road, drives others to the ditch, bespatters them with mud or chokes them with dust, and dashes through villages, hoots his way past the church where worship is going on, can do more in one day to cause all motorists to be hated than all the considerate drivers can do in the way of conciliation in a month.

Let it be borne in mind that the man in the street is not a particularly observant animal. He too often sees through the grim spectacles of prejudice, put on his nose by others, and resists as long as he can the clear light of the logic of facts.

"The text that suits not with his darling whim,
Though plain to others, is obscure to him."

Let it be remembered that one of the reasons why every energy should be put out to counteract opposition is that much of that opposition is not reasonable, but wildly unreasoning, and because it so is much more difficult to meet. The knowledge that an opponent is actuated by passion rather than reason leads too often to an unwise complacency—the foolish belief that because you have reason on your side you may let things take their course. This is a mistake in every case, and in this case it would be a fatal mistake. Every energy must be put out to allay passion and to convince reason.

The purposes of this paper will have been served if I have been able to supply my audience with facts or arguments which they may use, and which I trust they will use, to create enthusiasm and activity among our friends, to win over the indifferent and the opposing, and to convince the implacable that it is vain to attempt to crush, and wise for them to be moderate, and so to win the good will of all the considerate among motorists, and their assistance in putting down those who, though motorists in one sense, are the worst foes of automobilism—the scorcher and the hooligan of the road; and in providing a road which will be free of mud in winter and of dust in summer.

An omnibus has been delivered at Tokio, where it awakened much curiosity, which could only be slaked by an immediate initiation into the sensation of riding in this European conveyance.

A NEW FRENCH RECRUIT TO THE TWO-CYCLE*

FRANCE has found herself in somewhat the same anomalous position that has existed for so long in this country, in that but one prominent firm has devoted itself to the building of motors of the two-cycle type for automobile use. There is now, however, a new entrant into this field abroad in the shape of the *Dubois et Uzac* car, which is of considerable interest from the fact that its builders have departed considerably from the beaten path in the design of their motor, though the latter is laid down along lines somewhat similar to those employed in the Wolverine and Smalley motors, both of American make. Neither the crankcase compression nor the auxiliary external pump types have been followed, the initial pressure necessary to deliver the fresh charge to the combustion chamber being obtained by the use of a differential piston, which differs considerably in detail, however, from others of this type that have been

FIG. 1.—Sectional elevation Dubois motor.

built previously. This consists in the main of a central stationary tube provided with gas tight rings the same as the piston. Through this tube the connecting rod works the same as in the ordinary two or four-cycle motor. This tube is designated in the accompanying sectional elevation of the motor by the letter *F*. The piston itself is of the ordinary type so far as its upper part is concerned, but is of unusual length and at its lower end carries a collar or second annular piston *B*, also provided with a ring. As will be plain from the drawing, the piston bears externally against the cylinder wall and internally against the tube *F*. The latter, together with the outer wall of the motor, forms an annular chamber in which the piston *B* works.

Great Economy in Fuel Consumption.

According to the builders this arrangement results in the reduction of the friction to a minimum and no leakage is possible. A model motor built on this system, having a bore and stroke of 90 mm. (3 1-2 by 3 1-2 inches), installed in a 25-foot motor boat, weighing, with ten passengers aboard, in the neighborhood of 1,500 kilos (3,300 pounds), drove it at an average speed of 13 kilometers, or approximately eight miles an hour, on a consumption of but two liters per hour, or little less than half a gallon. During the course of the past year the same boat has covered 5,000 kilometers without any engine troubles. On a four-cylinder car rated at 30 horsepower, the cylinders of which measure approximately 4 1-4 by 4 1-2 inches, it was never found necessary to provide more than 16 liters per 100 kilometers, or about 3 1-2 gallons for 65 miles. A means of readily reversing the engine by means of the ignition, through a special system of wiring upon which the builders hold patents both in France and abroad, makes the motor particularly convenient for marine use.

The advantages of the motor will be more clear from a description of its construction and method of operation. Re-

ferring to the sectional elevation, Fig. 1, it will be seen that the cylinder is water-jacketed about the combustion chamber, the jacket *P* only covering the upper part of the cylinder. The lower portion of the cylinder is bored concentrically with the combustion chamber, its diameter being half again as large as the latter. In this double cylinder the pistons *A* and *B*, which are in one piece, move in the chambers *C* and *D* and are attached to the connecting rod *G*, while *Q* and *E* represent the crankshaft and crankcase respectively. The latter carries the central tube *F*, which is provided with piston rings at its upper end, while at its lower end it is made somewhat bell-mouthed to clear the connecting rod and is provided with an extension base by means of which it is fastened to the crankcase.

Details of Motor Construction.

In the head of the cylinder *C* there is inserted an automatic inlet valve *I*, while the lower cylinder *D* is provided with a second inlet valve of the same type communicating with the carbureter. The pipe *N* connects the cylinder *D* with the combustion chamber *C* through the medium of the first inlet valve mentioned, while the exhaust gases escape from the cylinder through the ports *RR* and the pipe *L*. At its upper end the cylinder *D* is provided with an opening which communicates with the crankcase through the medium of the pipe *K*. The cylinders *CD* are cast integral with their base, the same as the central tube *F*, which permits of the ready mounting of the whole on the crankcase by means of gudgeon pins and screws. The remainder of the details of the construction will be plain from the cross sectional view which has been referred to in the course of the above description.

The sequence of the various functions in the cycle of the motor are as follows: Assuming the pistons to be at the lower end of their stroke, and the combustion chamber *C* full of fresh gas, the piston *A* on its upward stroke will compress the gas and at the same time the lower piston *B* will aspire another fresh charge into the chamber formed by the wall *D* and the central tube *F*, through the valve *H*, which, owing to the depression produced by the upward travel of this piston, remains open during the entire stroke. At the end of the latter the charge is fired, the spark plug *O* being located near the inlet valve and placed at an angle. On the downward or power stroke, the fresh charge which has just been drawn into *D* is compressed by the piston *B* until the piston *A* reaches the end of its stroke, uncovering the exhaust ports *RR*, permitting the escape of the burned charge. The depression caused by the latter then causes the inlet valve *I*, in the head of the cylinder, to open and a fresh charge passes into the combustion chamber, aiding in the expulsion of the exhaust gases. This remains open for a considerable portion of the upward stroke of the piston *A*, or until the compression of the charge overcomes

FIG. 2.—Wiring diagram for reversing Dubois two-cycle motor.

*Translation from *L'Automobile*, by Charles B. Hayward.

the pressure on the other side of the valve. During this operation the cylinder *D* has again been replenished through *H*. The volume of *D* is slightly greater than that of *C* and the compression created by the piston *B* is calculated to insure a fresh charge sufficient to fill *C*. The speed and power are

FIG. 3.—Nine horsepower marine motor.

varied by throttling the mixture at the carbureter and advancing or retarding the point of ignition. If the ignition should be cut off when the motor is running, it will come to a stop after several revolutions, but, as has already been made plain, the charges under the initial compression given them in the cylinder *D* are conducted to *C* through *N* and are there recompressed prior to ignition. It is evident that the motor cannot come to a halt until the pressures in *C* and *D* reach a point of equilibrium, and at that moment the pistons must always be half way up or down in the course of their stroke, a position horizontal to the axis of the motor, the balance of the pistons and cranks aiding in this result. From this it will be apparent that the motor can never come to a stop on a dead center, and by means of a special form of commutator the motor is made self-starting in either direction.

Details of the Ignition System.

The high-tension system of ignition is employed, the spark plug *O* is connected to the positive pole of the secondary winding of the coil, the other being grounded, while the positive terminal of the accumulator is connected to the positive end of the primary winding and the other side—the negative of the accumulator—is grounded. The switch *A*, shown in Fig. 2, is provided with three points, number one being grounded, number two to terminal of the induction coil, and number three to the timer *B* on the motor, the switch lever being designed to cover two of the points at once. For instance, the motor has stopped with crank to the left of the axis of the motor, and it is desired to start on the reverse—that is, from right to left. The timer *B* on the motor is turned to the position *V*, a point corresponding to that of maximum retardation on the reverse, and at the same time the switch lever of *A* is turned to cover two and three. The first explosion suffices to start the mixture

flowing through *N* and it is then only necessary to alter the speed by advancing the spark or opening the throttle. To cite another example, let it be assumed that the motor has stopped in the same position as above mentioned, and it is desired to start it running ahead—that is, from left to right. The timer is then placed in the position *W*, corresponding to the point of maximum retardation when running ahead or normally. The switch lever is turned to cover the points 1 and 2. The first stroke will be in the reverse direction and immediately after its occurrence the switch is moved to cover the points 2 and 3, and as the next charge sent into the cylinder through *N* cannot be fired until contact is made at *B*, this causes the next stroke to occur in the opposite direction and the motor then takes up its cycle, regularly running forward. To speed up the motor it is only necessary to advance the spark as in the former instance.

These two examples demonstrate that, whether the crank stops to the right or to the left of the axis of the motor, and as already mentioned it cannot stop at any other points, the motor can be started ahead or on the reverse simply by shifting the position of the timer *B* and the closing of the primary circuit by the switch *A*. When under way, contrary to the method used in starting, the reverse is obtained simply by cutting out the ignition momentarily and then giving it an excessive advance, which causes a premature explosion and starts the motor in the opposite direction, after which the timer is immediately returned to the running point desired.

Lubrication is provided for as follows: The tube *K* unites the crankcase *E* with the upper part of the cylinder *D*. In the part of the cylinder in question a depression is produced by the descent of the piston *B*, and this space is filled by the pressure created in the opposite direction by the descent of the same piston in the crankcase. The big end and main bearings are lubricated by the splash of the oil in the bottom of the crankcase and the circulation of air set up by the means just described suffices to carry considerable of the oil up into the chamber *D*, effectively oiling the pistons *A* and *B*. This system is necessarily proportioned to the speed of the motor and ceases immediately the latter stops. The level of the oil in the crankcase is maintained constant by a float-feed placed in the supply pipe. There seems to be little doubt that the attention of a few large manufacturers on the Continent, if devoted to the development of the two-cycle motor with the success that has apparently rewarded the inventor's efforts in this case, would be of far-reaching benefit to the automobile industry the world over. Particularly where the French industry is concerned, the two-cycle type of motor appears to have suffered more from inattention than anything else—neglect, it might be called.

"ELECTRICITY ONLY WARMS THE BIRD'S FEET."

Every now and again the "automobile reporter" of some daily is assigned to cover an accident or an interview and the way he dishes it up is something to make the informer's hair stand straight on end. Two of New York's leading and most respected dailies in the course of the description of an accident that was accorded a top of column, front page position, with display head, and in which an elderly woman had been run down by an auto on Broadway, made the statement that her clothes had caught fire from "hot coals dropping from the carbureter." Of much more recent occurrence is the deviation from the straight path of technical rectitude of that scribe who quoted a well-known designer as saying that "the piston rod of a gas engine worked up and down in the cylinder, accelerated by the explosions in the carbureter, which was the reason why the stroke could not be made longer." These and their kind are certainly diverting and seldom do any harm, but such can hardly be said of the break of the editor of an automobile paper, who, in answering an inquiry as to why birds alighting on electric wires were not killed by the current, naively stated that the "electricity only warmed their feet."

FIG. 4.—Carbureter side, four-cylinder motor on car.

LETTERS INTERESTING AND INSTRUCTIVE

The Noise Made by Valves.

Editor THE AUTOMOBILE:

[657.]—I have a four-cylinder touring car, of 24-horsepower, which seems to me to have very noisy valves. The car is a 1907 model, and with this exception runs as quietly as an electric. The muffling is beyond criticism, there is no perceptible noise from the gears, and the squeaking and creaking that accompanies the progress of so many cars is entirely absent. But the valves keep up a most interminable clacking—perhaps no worse than with other cars, but made more pronounced by the absence of other noises—and if it is possible I would like to remedy this defect, to which end I will be pleased to receive any suggestions you or your readers may have to offer. Is there anything about the valve seatings, the amount of lift, or the adjustment or form of cams that change the conditions so that less noise will be made?

Denver, Colo.

DR. B. A. PEABODY.

Ordinary poppet valves are perhaps the most difficult detail involved in the mechanism of a modern high-grade car to make very silent. The very nature of their operation, requiring sudden lifting and a return to a metal seat, makes it impossible to expect an absolute elimination of noise from such sudden clashing of metal-to-metal surfaces. Much can be done, however, in the design of an engine, to reduce the noise by a judicious proportioning of valve lifts and diameters. The present prevalence towards valves of large diameter and very slight lift is an expression of this tendency. Also, valves with flat instead of beveled or mitered seats are coming widely into use because they afford a given opening with the least lift. The objection to valves of large area, especially exhaust valves, is that they require proportionately heavier and more durable cam mechanism to open them against the residual pressures within the cylinders, without entailing undue wear. A further objection, from your particular standpoint, is that the design of your motor is likely to be such that any increase in valve diameters is likely to prove exceedingly expensive, if not absolutely impracticable. Reduction of the lift is less difficult, but should not be done unless you can change to flat seats. Possibly your trouble may be due to an often-neglected detail of cam design—the form of the closing contour. If this is too abrupt, the closing means may snap the valve to its seat much quicker than is desirable. Sometimes changes in the exhaust or intake piping will reduce valve noise. Aluminum intake manifolds are especially apt to possess a certain resonance which seems almost to magnify small noises, while the presence of small openings in intake manifolds is another cause of noise escaping, which otherwise might be very effectively smothered.

No Symptoms from Which to Make Diagnosis.

Editor THE AUTOMOBILE:

[658.]—Will you kindly answer the following through the columns of your journal?

Can you inform me how I can get more power out of my single-cylinder car? The engine seems to work all right, and also the spark coil and plug, yet it does not seem to develop the power it is rated, which is four horsepower. It seems to be all it can do to climb a 5 per cent. hill.

Meshoppen, Pa.

H. N. F. C.

Without knowing anything further than the meagre account that you give in your letter, it is next to impossible to state with any degree of certainty just why your motor does not develop a greater amount of power. There are several things that may be wrong. The valves may need regrinding or the piston rings replacing, or again the only trouble may be that one of the brakes on the car is dragging. The mere fact that the engine apparently runs all right is an indication of nothing more than that it is not deranged to the extent of preventing its operation. Under such circumstances the compression would naturally seem to be the first thing to investigate, as, if it be efficient in this respect and responds readily to the spark and throttle, there is no reason why it should not develop its full rated output.

Vibrators in Vacuo.

Editor THE AUTOMOBILE:

[659.]—Why would it not be a good idea, in the attempt to refine ignition systems to a maximum of efficiency and reliability, to seal the vibrators in exhausted glass bulbs, within which they would be protected from most of the troubles that now cause their uncertain working? The use of a vacuum in this way would prevent the corrosion between contact points, which is due to the oxidizing effect of the air, and would do away with the mechanical lag of setting the vibrator in motion, which is principally because of the air resistance. There would be no possibility of changing the adjustment, but this would be an advantage rather than an objection, because a proper adjustment could be made beforehand, and afterwards this adjustment could not change because of the complete protection from disturbing factors.

Hagerstown, Md.

HOWARD CUSHMAN.

While the plan you suggest might prove to have some advantages, it is very doubtful if they would be exactly as you state them. In the first place, the "corrosion" you refer to is not so much corrosion as it is an actual fusing away of minute particles of the contact points—an action that would continue to take place in a vacuum about as readily as in air. This effect, therefore, would sooner or later disturb the adjustment, just as it does now, making readjustment, through some ready provision for it, imperative. And if such a necessity arose, as it undoubtedly would, it is not likely that the average motorist would be inclined to enthuse over a construction that placed all means of adjustment absolutely out of his reach. As for the lag, this certainly is attributable almost solely to the inertia of the vibrator blade, for the amplitude of the vibration is too small to make air resistance a serious factor, except as it may possibly prevent, after the movement is under way, as rapid a vibration as might be produced in a vacuum. In connection with certain automatic-telegraph experiments, as well as in some "seeing-by-wire" devices, we believe the vacuum-surrounded vibrator has been utilized to some extent.

Positive Functioning Under Throttled Condition.

Editor THE AUTOMOBILE:

[660.]—What is the degree of compression, in pounds per square inch, now most preferred in automobile engines? Is it not a fact that most automobiles are much overpowered, with the result that normally the engines work under considerable throttling? And if the foregoing is a fair statement of the case, what becomes of the advantages of compression when only a comparatively small charge is inspired, with the result that the compression is lowered in proportion?

CHAS. M. ENGELHARDT.

Springfield, Mass.

Your questions all strike at what is a widely-admitted fault of modern internal-combustion engines. No mechanism is perfect, and the variable compression with variable throttling, which is a feature of current gasoline-motor practise, perhaps may be regarded as an imperfection. On the other hand, the system used with the Adams-Farwell car, of deliberately varying the compression by inspiring full charges and afterwards blowing out a proportion of each, might be held to support a contrary view, since it is used very successfully. Nevertheless, there is no question about the facts as you state them. Experience has proved it expedient to propel cars by very powerful motors, capable of making good speed up the worst hills and over the hardest going. The unavoidable result is that under less strenuous conditions only a fraction of the maximum power available is required, and, therefore, with the best-established means of control over power output, the compression must be diminished by the wire-drawing consequent upon throttling. One well-known American engineer—the designer of a foremost American car—recently patented a system of control providing constant compression through the use of air volumes, containing no fuel, introduced within the cylinder but kept separate

from the throttled charge by an application of the principle of stratification. All of this, of course, applies specifically to the four-cycle engine. With two-cycle engines practically constant compression is maintained, because, under throttling, in proportion as less charge is admitted more exhaust is retained, the result being a practically invariable total. The real gain is less than might appear, however, since the mixture is exceedingly adulterated and impoverished. For example, if the charge is throttled to one-sixth of its maximum volume, and contains one-tenth part of gasoline vapor (both usual figures), the effect upon the cylinder contents is best expressed in the fact that they then consist of one volume of gasoline vapor, nine volumes of air and fifty volumes of inert gases—incidentally proving that mixtures very much leaner than are commonly approved can be used with a high degree of success.

"Starting on Compression" Again.

Editor THE AUTOMOBILE:

[661.]—Some weeks ago, the statement appeared in your paper, in an answer to one of your correspondents, that an automobile engine would not "hold compression," and that when an engine started by the spark it did so by the explosion of "uncompressed mixture." If this is true, and uncompressed mixture will give such a powerful impulse, why are engines not made to run without compression? It seems to me that it is one thing to sit in an office and undertake to give right answers to every question that anyone can ask, but it is quite another to get practical experience by running cars, which is the only real way to know what we are talking about.

M. A. MULLINS.

Reading, Pa.

Your outspoken skepticism concerning the authority of our answer to a certain question apparently fails to take into account the fact that there are thousands of internal-combustion engines to-day in use which run altogether without compression. An engine cycle in which compression is not used will fail to give as high explosion pressure or as great efficiency as when compression is used, but as far as mere working is concerned it works very well. So you may regard it as well established that an uncompressed mixture will upon ignition give an impulse amply powerful to turn over an automobile engine declutched from the driving mechanism. As for our presumption in undertaking to give right answers to every question that any one can ask, if you will refer to your files of THE AUTOMOBILE and glance back over the correspondence columns you will find that we have not infrequently failed to give satisfactory answers, apparently because we are no more infallible than you seem to regard us. We are always pleased to hear from a reader who can explain something better than we can ourselves. We have, however, access to a few cars from which we occasionally gain a little practical experience. Because of this we know that if you have a car that starts from a spark it will also start equally well if you first open the petcocks and absolutely relieve every trace of residual compression. Try it and see.

Some Ignition and Carburetion Queries.

Editor THE AUTOMOBILE:

[662.]—I have a few questions that I would like to have answered, if it is not too much trouble: (1) How high a battery voltage would a Pittsfield quad coil stand without danger of burning? (2) Will an ordinary carburetor carburet kerosene without a heating jacket? (3) Has anyone ever equipped a car with two fuel tanks, one for gasoline and one for kerosene, using the gasoline to start the motor and kerosene to run on after the motor is warmed up? (4) I have seen porcelain spark plugs chipped and broken at the hot end. Now, it seems to me that the pieces of porcelain must have been hammered to pieces by piston. Now, if such be the case, are they likely to do serious damage to the motor?

Moline, Mich.

A SUBSCRIBER.

(1) Not knowing exactly the amount and size of the wire used on the coils you mention, we cannot accurately state the potential that they will stand without a breakdown in the insulation, commonly known as burning out. Coils for ignition purposes, however, are generally wound to take current at a

potential of six volts, and anything over this is not advisable. Of course, all coils have a factor of safety and are capable of standing an overload, which is what subjecting them to a higher voltage than they are designed for amounts to, and the proportion that this factor of safety bears to the normal capacity of the coil represents the limit to which the potential may be increased without damaging it, assuming meanwhile that the amount of current remains the same, only the voltage being increased. For instance, a six-volt coil with a factor of safety of 100 per cent. would be capable of standing a potential of twelve volts. This matter was discussed somewhat at length under the caption of "Increasing the Dose Is Apt to Be Dangerous," which appeared in the issue of January 24, 1907, of THE AUTOMOBILE.

(2) It will if it can be maintained at the proper temperature by some other means, as a much greater amount of heat is required to properly vaporize kerosene than lighter fuels, regardless of the manner in which it is applied

(3) We have come across instances of this kind from time to time in looking through foreign automobile periodicals, but do not know of any cases where it has been done on this side of the Atlantic. In one of the cases referred to, a Scotch motorist gave his experience with kerosene over a period of two or three years.

(4) The plugs have not been "hammered" to pieces by the pistons, as you surmise, but have succumbed to the intense heat and vibration. The porcelain of which the insulating core of a spark plug is made is an abrasive and if it managed to get in between the piston and the cylinder walls, as would most likely be the case in a vertical engine, it would do damage. We should think, however, that the particles would be of such small size as to be blown out the exhaust in the great majority of cases.

Direct Current Dynamo for Ignition.

Editor THE AUTOMOBILE:

[663.]—Will you be good enough to answer a question through the columns of your journal, which we read with increasing interest in each number. We have a single cylinder car that we use in connection with our business, and we find trouble in getting good dry batteries; they soon run down and are not dependable; we are a long distance from factories and any headquarters for motor supplies, and suspect that most of the batteries we get are old.

Can we put an Apple, or other make of dynamo on our car, run it by friction from the flywheel, and get what current we need without the use of dry batteries or any other form of stored current? We saw in a recent issue of "The Automobile" where a subscriber had used one on an Elmore car with good success. Is such a scheme practicable, and, if so, please give directions how to connect same, and if practicable, why are they not generally used on all cars? What are the faults? If the scheme is all right, please give size or number of dynamo required and address of concern manufacturing same.

SINGLE CYLINDER.

Charlottetown, P. E. I.

Small direct current dynamos such as you mention are largely used and are usually driven by friction from the periphery of the flywheel, so that there is no reason why you cannot successfully apply such a system to your car. In earlier days, the principal faults with the small dynamo were its small capacity, i.e., current output, and the crude type of governor used, which frequently failed to work and caused the dynamo to burn out when the engine raced. We believe these faults have been entirely overcome long since. Regarding size required and details of installation, we prefer to refer you to the makers, whose announcement you will find in our advertising columns.

Advantages of Offsetting the Cylinders.

Editor THE AUTOMOBILE:

[664.]—Will you be kind enough please to give me some information in regard to the advantages and the disadvantages of offset cylinders. I am constructing an engine 4-3-4 by 5-1-2, and am interested whether or not to set off the cylinders 7-8 inch. Knowing that you are in a position to furnish direct and intelligent information on a subject of this kind, I take this means of requesting same.

R. W. BLAKE.

Bryn Mawr, Pa.

The question of offsetting the cylinders on the crankshaft is not a new one by any means, though many are under the impression that it is something that is the outgrowth of the development of the internal combustion motor; but such is not the case, as it was used on old-time single-acting steam engines many years ago. As is well known, the internal combustion motor, particularly as employed on the automobile and in the motor boat, does practically all its work on one stroke. The exhaust stroke is an idle one and on the compression stroke comparatively little work is done, so that the side-thrust of the piston against the cylinder wall, due to the angularity necessitated by the use of a short stroke and connecting rod, is concentrated on the power stroke. To overcome this, a great many makers have adopted the plan of offsetting the cylinders. The amount to which this should be done in order to gain the greatest advantage will be found at a point where the thrust is lessened to the greatest degree on the power stroke and at the same time not increased excessively on the compression stroke, otherwise the desired advantage is apt to be lost due to the thrust set up by the excessive angularity of the connecting rod on the latter.

The offsetting is usually calculated with reference to the length of the stroke and varies from 10 to 25 per cent., although in the case of the Armstrong marine motor, which is an extreme, the offset given is the equivalent of the length of the crankthrow. The Duryea motor—the first of its kind in this country—is offset 3-4 inch in 5, or 15 per cent.; in the Moore but 3-8 inch offset is given, while in the Craig-Toledo it is 1 1-4 in 5, or 25 per cent. The Rambler closely approaches this, but the same effect is obtained by offsetting the connecting rod on the piston, instead of altering the relative positions of the cylinders and crankcase. The actual amount given is 1 1-8 inches in 5 1-2, or 20 per cent. In the case of the American Mors it is 1 inch in 6, or slightly over 16 per cent. Other American makers who have adopted the principle are the Winton, Aerocar, Berkshire, Frayer-Miller, American, St. Louis, Frontenac, Simplicity, American motor truck, Dolson and Austin.

Compression Data and High-Speed Engines.

Editor THE AUTOMOBILE:

[665.]—I would like to have you answer the following questions through the columns of your paper. In speaking of compression I mean the difference due to design, and not to leaks of any kind.

(1) Does the speed of an engine vary when the compression is changed, or what effect does increasing the compression have on the speed, other things being equal?

(2) If the speed of an engine varies with the compression, in what ratio does it vary?

(3) Principally, how does a high-speed engine differ from a low-speed engine.

(4) Why will not a high-speed engine work well at a low speed?

(5) If an engine with large valves and high compression will work at high speed, will same work well at low speed if compression is lowered?

(6) What is the average compression used on American road machines and that on track machines; that is, pressure in pounds and percentage of compression space?

(7) Can you tell me where I can obtain books on gasoline engine design that will give all formulas, etc., for automobile engine design?

A. H. CAIN.

Roodhouse, Ill.

(1) It does. The speed is increased.

(2) This is somewhat of a poser to answer offhand. We cannot enlighten you as to exactly what relation the compression bears to the speed. Probably some of our subscribers who are more conversant with the subject will come to the rescue. Hiscox gives a table of data showing a comparison of the theoretical and actual efficiencies of a four-cycle gas engine with varying compression and also a table of compression pressures and clearance ratios, but so far as known there are no data extant in the shape of a compression and speed table.

(3) The chief difference between the design of a high-speed and low-speed engine is to be found in the length of the stroke.

(4) Principally because, at a low speed, it is only receiving a fraction of the impulses per minute that it was designed to

receive. This on the presumption that by working well you mean delivering a proportionate part of its rated output at a low speed.

(5) It will probably work satisfactorily for all ordinary purposes, though such a radical change in the design is apt to be detrimental to its efficiency.

(6) Doubtless 60 to 70 pounds represents a close approximation to the average compression of American cars, with a slight increase in the case of specially designed racing machines. It is customary to make the compression space 25 to 33 1-3 per cent. of the volume displaced by the piston, these figures probably representing the two extremes of current practise, so that something like 29 to 30 per cent. might be considered a fair average.

(7) We have sent you a catalogue under separate cover.

Probable Life of the Ignition Magneto.

Editor THE AUTOMOBILE:

[666.]—Will you kindly tell me through your question department whether or not a magneto will generate a magnetic current indefinitely. If not, what time would be its probable life if used on an automobile? You will greatly oblige.

C. F. NIXON.

Leominster, Mass.

We presume your question is as to the probable life of the magnets—in other words, how long will the magnetic field of a magneto retain its strength?—for as soon as the latter fails the machine will no longer generate a current when run. A magneto generates an alternating electric current as ordinarily constituted, or a direct current when equipped with a commutator. The word current is not ordinarily used in connection with magnetism. No magnet will retain its strength indefinitely, but we have known magnetos of the class used on telephones, which are practically the same as those used for low tension ignition, barring their smaller size, to be apparently as strong as ever after fifteen or sixteen years of constant service. Heat and vibration are both detrimental to magnetism, but the chief cause of its loss is the removal of the armature from between the pole pieces, leaving the magnets stand in this condition. There has been a vast amount of misconception on this point, where the automobile magneto is concerned, and much of it still exists. Popular knowledge as to the essentials of the magneto is so scant and usually so erroneous that the failure of the magneto to work from almost any old cause has usually been put down to a failure of the field magnets. We have known of one or two instances where an autoist has returned his magneto to the maker with instructions to remagnetize the field, as it had become weak, when nothing but cleaning or a little adjustment was required. As the maker does not go to the trouble to disillusionize the customer, the latter thinks he has successfully diagnosed the trouble and leads others to think likewise. No instance has ever come to our knowledge where a properly constructed and cared for magneto has lost its magnetism to an extent sufficient to interfere with its working. We should say the magnets were good for eight to ten years at the least; remagnetization can be done in a few minutes at a cost of a dollar or less.

Influence of Auxiliary Exhaust on Inlet Valve.

Editor THE AUTOMOBILE:

[667.]—I have a four-cylinder 1904 car, and last year bought new cylinders and necessary parts for the auxiliary exhaust. After fitting these carefully, I could never get more than half the power out of the engine, but after cutting out the auxiliary exhaust the car worked as good as it ever did.

The makers of the car insisted that the engine was not properly adjusted or it would work with the auxiliary, and asked to have the car brought to the factory. This I did, and after a week or ten days' testing and adjusting, decided that it would not work with the auxiliary on account of the automatic intake—consequently the auxiliary was cut out permanently for the season.

Now I can't understand what the automatic intake has to do with the auxiliary exhaust, which is fitted with check valves. Perhaps some of your subscribers can explain. I will now fit my engine with the mechanical intake, hoping that the results will be satisfactory. Any information on the subject will be appreciated.

Watertown, N. Y.

C. D. W.

We are not sufficiently familiar with the design of your car, particularly in its rebuilt condition, to be able to throw much light on the matter regarding which you inquire. On general principles, however, we should say that in all probability the reason why the auxiliary exhaust deranges the working of the automatic inlet valve is to be found in the fact that the former tends to equalize the pressure in the cylinder with that of the atmosphere at the end of the exhaust phase, thus preventing the formation of a vacuum in the cylinder and in consequence the working of the inlet, which depends upon this. If there is an appreciable difference between the pressure in the cylinder and that of the atmosphere the inlet valve is bound to open on the suction stroke, unless prevented by too stiff a spring, or similar cause, which we presume is hardly likely to exist in view of the investigation you mention. We have no doubt that the fitting of mechanically operated valves will entirely eradicate the trouble.

A Criticism of No. 585 from Abroad.

Editor THE AUTOMOBILE:

[668.]—Your interesting paper reaches me regularly, and I am much interested in its contents. In looking through the issue of February 21, you have under the heading, "A Twenty-five Per Cent. Grade About the Limit," an inquiry, No. 585, to which you

WINTON CLIMBING ONE-IN-FOUR GRADE AT PRESTON, ENG.

reply stating certain facts as to the hill-climbing power of automobiles. It is dealing with this heading that I should like to call your attention to the illustration on page 31 of the accompanying catalogue, together with a surveyor's certificate of the gradient up which the car is pictured climbing. The surface of this hill, as can be seen by the illustration, is exceedingly bad, but, in spite of this, the Winton Model "K" had no difficulty whatever in negotiating it. If you think the matter of sufficient interest to your readers, you can make what use of it you like.

You may have a representative over here on a trip shortly, and I shall be glad to meet him and show him the fine premises owned by the Winton Motor Carriage Company in London, where they possess a floor space of no less than 13,000 square feet on one of the main arteries of London.

W. L. DUCK, Mgr.,
WINTON MOTOR CARRIAGE COMPANY.
London, S. W., Eng.

The surveyor's certificate mentioned is to the effect that the hill in question is 495 feet long and on the first hundred feet has a rise or inclination of one in six, while on the last 150 feet, which is the steepest part of the hill, the rise is one in four.

A Simple Method of Figuring Horsepower.

Editor THE AUTOMOBILE:

[669.]—Referring to Letter No. 600, under the head of "Data Wanted on Engine Testing," I have a simple and practical formula or method of computing brake horsepower taken from about 100 brake tests of different makers and dimensions. It is horsepower equals total volume in cubic inches per minute divided by 5,000; or, formula equals V.P.M.C. divided by 5,000; or total volume per

hour in cubic feet divided by 173.7 equals horsepower. Formula equals $\frac{T. VP H}{173.7}$ equals horsepower.

I will forward the details of these results of figures if you wish them.
R. C. MATLACK.
Chicago, Ill.

We have no doubt that the figures resulting from such a number of tests of different makes of engines would be interesting and would be pleased to see them.

TWO SOLUTIONS OF THE MYSTERY OF NO. "636."

Editor THE AUTOMOBILE:

[670.]—In your issue of March 14, letter No. 636, re "mystery." This is certainly an interesting occurrence, and would probably puzzle anyone not versed with the nature of acetylene. If I understand aright, the copper tubing was used to convey the acetylene from the generator to the lamps, and it was certainly an error to employ copper for the purpose. Acetylene coming in contact with copper will form a deposit which we might call electrolyte, which, when treated violently, will break, and on breaking produce a visible spark. Of course, there must have been an explosive mixture, which ignited to produce the detonation. Writer has observed copper pins used in an acetylene generator, and has produced visible sparks from same by cutting through the upper crust with a knife.

I trust this will enlighten my friend Burtiss.
St. Williams, Ont., Can. R. KURTZ.

ACETYLENE AND THE PRESENCE OF MOISTURE.

Editor THE AUTOMOBILE:

[671.]—I would submit the following as an answer to No. 636: Acetylene gas in presence of moisture produces an explosive compound from copper, called copper acetylde ($C_2 Cu$), and when dry it explodes very easily from friction or blow, or when heated to 120°. It was owing to this explosive compound (formed inside the copper tubes by the acetylene gas, containing a percentage of water vapor, produced from heat of the carbide in the generator) and not to any remaining gas in the tubes that caused the fireworks. Perfectly dry acetylene gas, as sold by the Prest-o-Lite people in their storage tanks, will not form this compound to any extent, as moisture is necessary to the chemical reaction.

Akron, O. C. A. WILLIAMS.

SHEDDING A LITTLE LIGHT ON NO. 633.

Editor THE AUTOMOBILE:

[672.]—In reference to query No. 663, I think I can possibly shed some light on the subject referred to therein. I have heard it said that the rate of propagation of ignition of gasoline vapor to be 60 feet per second, under normal, that is, atmospheric pressure, and that this rate is directly proportional to the pressure. My authority for this statement is the mechanical engineer of one of the largest automobile factories in the country.

Cleveland, O. CHARLES E. BAILEY.

IN EXPLANATION OF "631's" QUERY.

Editor THE AUTOMOBILE:

[673.]—In re letter No. 631—"A Peculiar Trouble." I have noticed the same trouble in lubrication of six-cylinder engines, and believe it to be caused by the crankcase, for the oil always leaves the section which vibrates most and works toward the section which vibrates least. I have never seen this trouble in six-cylinder engines which have every other partition light, with no passage over the top.

H. A. S.

STATIC ELECTRICITY SUGGESTED AS CAUSE.

Editor THE AUTOMOBILE:

[674.]—In reference to B. A. Burtiss' letter No. 636, I should say the gas was exploded by a spark, caused by the discharge of static electricity contained on his body to the copper tubes. I do not consider this as necessarily final, but merely give it as my opinion.

Morristown, N. J. W. G. HURTZIG.

WORTH THE PRICE OF A YEAR'S SUBSCRIPTION.

Editor THE AUTOMOBILE:

[675.]—Although I have been a reader of your magazine for some time, it is only recently that I have been a subscriber. I think that the page "Letters Interesting and Instructive" is worth the price that you ask for the whole magazine.

Rochester, N. Y. H. A. STRICKLAND.

FOR Those Who Tour To Virginia's Exposition

ON THE PICTURESQUE SHENANDOAH VALLEY PIKE, WHERE TOLL GATES ARE FREQUENT BUT THE ROADBED IS EXCELLENT.

INTEREST in automobile touring south of the Potomac river has been growing very rapidly for the last two or three years. The idea has been generally prevalent that tours in Virginia and towns south thereof should be undertaken with caution, on account of the bad state of the roads. This remains equally true to-day, and yet, with the increased capability of the automobile to cover long distances in almost any kind of country it is not surprising that actual trips have already been successfully carried through this section.

The most notable of these is perhaps the trip from New York to Ormond, Fla., made by an Oldsmobile touring car in December last, notes and map of which appeared in THE AUTOMOBILE at that time, together with a discussion of other possible routes through the South. As the Ormond-Daytona season is now practically over, it is probable that no more trips through to Florida will be undertaken, at least until next fall.

On the other hand, interest in touring to and from the Jamestown Exposition, Norfolk, Va., has been increasing very rapidly. It has been suggested that this would be a good terminus for the 1907 A. A. A. tour, although the latter consensus of opinion seems to be that the hotel accommodations will be inadequate and the difficulties practically insurmountable for a large party.

This does not by any means lessen the interest in the route south of the Potomac, and the chances are that a number of individual trips will be made to and from the exposition, irrespective of whether or not the Glidden tour goes that way. Last summer Augustus Post, former chairman of the A. A. A. Touring Board, made a complete trip from the North to Jamestown by the way of Washington, Hagerstown, the Shenandoah Valley, Richmond and Norfolk. This preliminary

exploration was made by Mr. Post under the auspices of the Jamestown Exposition authorities, the Norfolk Automobile Club and the Richmond Automobile Club.

Full and complete notes were furnished by Mr. Post, both to the Exposition authorities and to "THE AUTOMOBILE Official A. A. A. Blue Book." In connection with the publication of this matter in the "Blue Book," a double page map of the Shenandoah Valley on the north and the Virginia coast on the southeast has been prepared for publication in the 1907 edition. The map referred to, somewhat reduced for convenient publication in THE AUTOMOBILE, is reproduced herewith in connection with an article by C. H. Claudy, dealing in a less detailed manner with a corresponding trip made by himself with a well-known autoist of Washington, D. C., over substantially the same territory.

The official route to the exposition, compiled by Mr. Post, will not be printed for some little time; its length precludes it from publication in THE AUTOMOBILE. Mr. Claudy's story, however, gives an interesting view of practically the same country as seen by himself, although in some particulars the trip made by him varies from that made by Mr. Post for the exposition. In that degree also it will vary from the map published herewith.

There are two ways of going from the capital of the United States to the capital of Virginia. One is by way of the old Telegraph road through Manassas and the other is to and through the Shenandoah Valley pike. The first is shorter, but very much rougher; the second, a longer route, yet allows much better time to be made on account of the good roads. No one ever having experienced the two would hesitate for an instant to choose the longer route, which is therefore given here as the most practical and satisfactory route to accept.

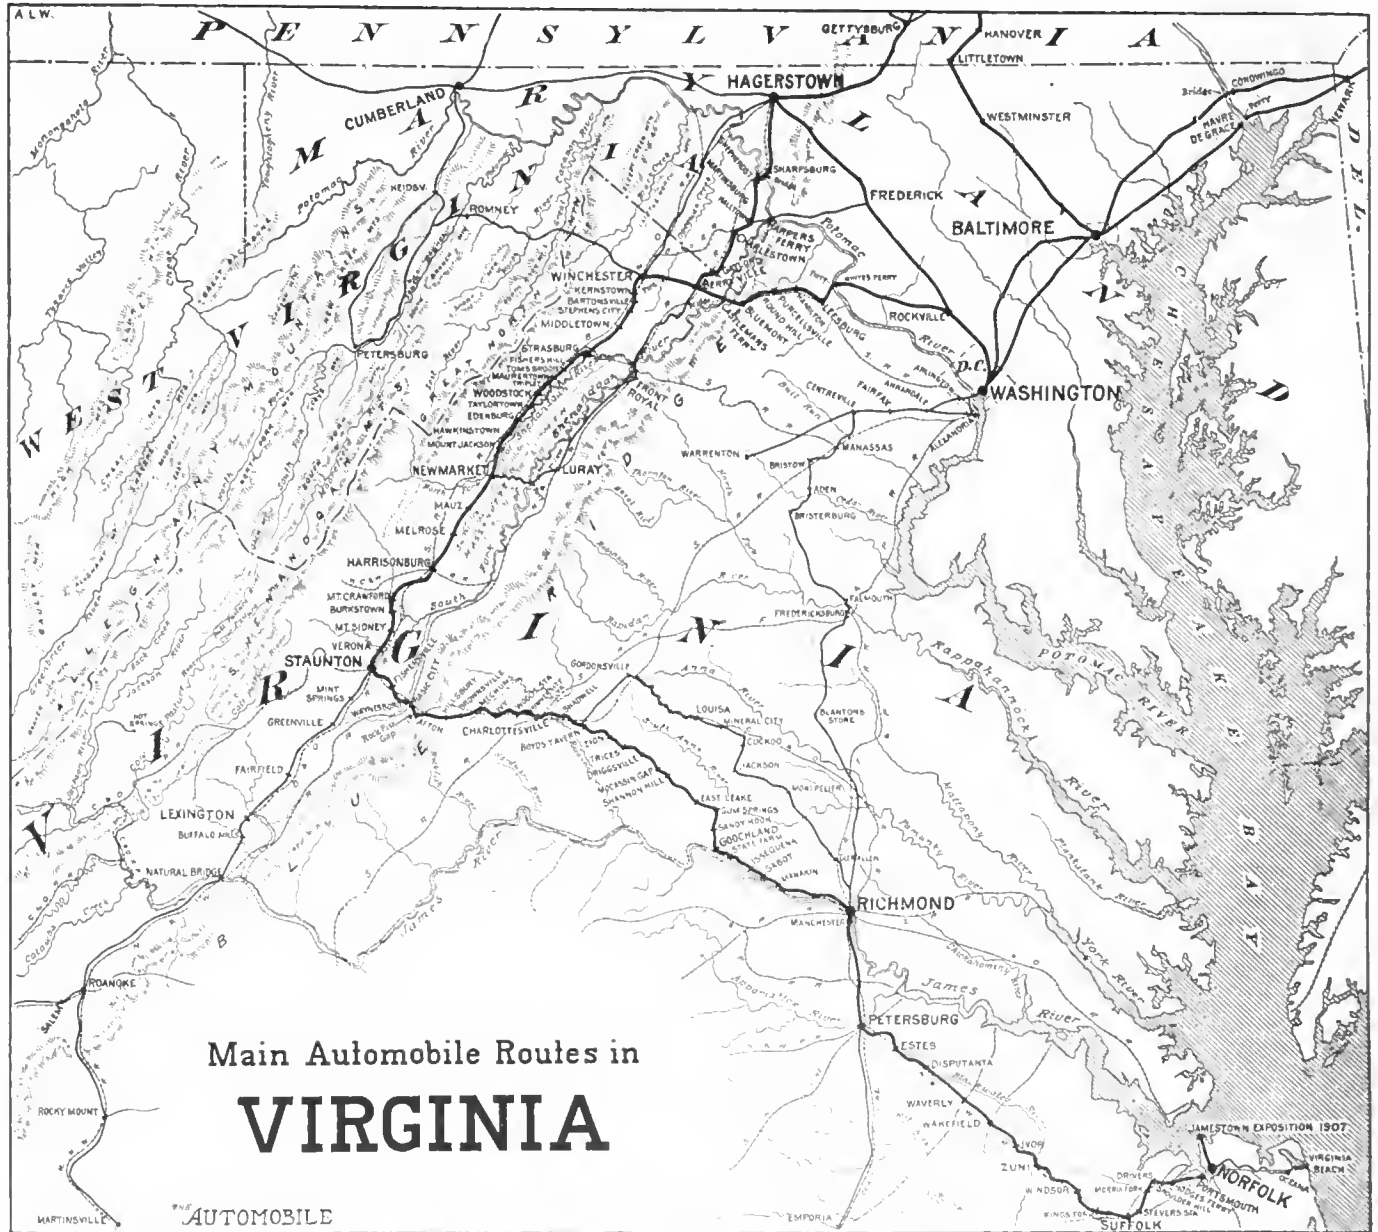

WHERE TIRE CHAINS ARE VERY USEFUL.

There are two ways of approaching the Valley pike from Washington. One is by way of Harper's Ferry, reached through Frederick, Jefferson, Weverton, Knoxville, Harper's Ferry, Charlestown, Berryville and Winchester. The other is by way of Rockville, Md., decidedly the shorter, equally good in road, but not so much good scenery.

Proceed out any lettered street in Washington westward to Thirty-second street; follow the car tracks north to Rockville, fourteen miles, over a very good country dirt road. Keep straight ahead through Rockville, over a country road running north, usually good, with occasional hills and rough places, to White's Ferry, over the Potomac, twenty-three miles from Rockville.

where a toll charge of 25 cents is made. Follow straight, though sometimes rough, road over the Gap and down the other side across a small ford and on to Castleman's Ferry (now a bridge). Run over the Shenandoah river, where a toll of \$1 is exacted, to Berryville, seventy and five-tenths miles, where again a toll of 25 cents is due.

Cross railroad tracks outside of Berryville and pay another 25 cents toll, eighty-two miles. At Winchester bear sharply to the left out Braddock street and pass through three toll gates to Strasburg, where take local directions for Woodstock (road turns sharp right), passing through three more 10-cent toll gates. Woodstock is 112 miles from Washington and a good place for a

Here cross the river on the ferry (ferriage 50 cents per car and four people) and climb the steep bank on the other side of the river. One mile further find the Leesburg turnpike, there bear left for Leesburg, Va., eight miles from White's Ferry and forty-five miles from Washington. Here find a toll gate, where a 10-cent toll is charged, and a book produced which the motorist must sign with name, address, number of Virginia license, direction going, and the date.

Proceed straight through Leesburg for Hamilton, Purcellville and Round Hill, all on the pike, which runs straight through them, for Bluemont, sixty-two and five-tenths miles from Washington. Here make sharp right turn for top of Snicker's Gap,

country meal. Proceed straight through on pike to Millertown, Hawkinstown and Mt. Jackson, toll gate at each place, with book to sign, to New Market, Va., 131 miles.

Visit Luray and the Caverns.

If no detours are to be made, pass straight through, but if possible to spare the time spend night here and turn sharp left next day for Luray and the Caverns, fourteen miles. Road is horribly rough and rocky, but can be covered inside of two hours with almost any machine and in one hour with a good climber. Road is plain, over Massanutten mountain, where a beautiful view is to be had, and 15 cents toll paid each way on top, four miles from

New Market. Cross ferry over Shenandoah at White House Ferry (25 cents), ten miles from New Market, and follow road to sign, making left-double-back, as sign points, to Luray Caverns.

Charges are from 50 cents to \$3 per head at Caves, depending on hours, whether excursion day or not, and number in party. Sight is most wonderful and beautiful and the hour and a half spent in Caves well worth the highest price charged. Luray Caves are said to be the most beautiful, though by no means the largest, in the world. Take dinner at Lawrence Hotel (in spite of contrary directions from ferryman, who "caps" for another hotel), one mile from Caverns. Gasoline can be obtained here if necessary.

Return same way to New Market, and from there proceed down pike to Harrisonburg, three toll gates, 150 miles from Washington. Harrisonburg has a garage, where a machine may be left over night at a charge of \$1, and gasoline obtained. Also very fine modern hotel, with rather poor café.

Toll Gates Are Very Numerous.

Leave Harrisonburg on pike for Staunton, passing through six toll gates, and having clear, straight road to Staunton, 177 miles from Washington. Staunton is a good-sized town; here garage and machine shop can be found, also gasoline and oil; Hotel Beverly is best in city. Leave Staunton by Johnson street for Waynesboro, twelve miles, over very good dirt road. Pike ends at Staunton. Waynesboro to Meechum's river is a hard pull, taking in a mountain pass (Rock Fish Gap), one mile up and one down the other side. This is as rough and rocky a stretch as it would be possible to negotiate a car over. By all means have and put on gripping chains, particularly in wet weather. Go very slowly and carefully down other side—dangerous to speeding. Meechum's river is seventeen miles from Waynesboro.

Here turn sharp right at railroad tracks and again sharp right 300 feet further on, to Charlottesville, forty miles from Staunton. Follow car tracks past University of Virginia down to business section. Here turn left on any cross street to High street. Out High to right to bridge, two miles, where turn right across bridge. Seven miles from Charlottesville take left fork at pretty country mansion called La Forche, for Gordonsville, twenty-one miles from Charlottesville. Road is fair out of Charlottesville, but gets worse as Gordonsville is approached, and is very bumpy last five miles; also very sticky in wet weather—chains are a necessity. Gordonsville has a very fair country hotel (Keegan House), where a good dinner can be secured, but the hotel is right on the railway and sleep is difficult. Gasoline sometimes to be had; if not here, then at Louisa Court House, which reach direct south from Gordonsville over fine country road. However, this run crosses the railway tracks fourteen times in the fifteen miles to Louisa. At Louisa gasoline is 25 cents per gallon.

Leave Louisa on straight road and first fork beyond turn left and follow railroad tracks to Mineral City, six miles. Two hundred yards beyond old mill at Mineral City take road to left across railroad and follow tracks to Cuckoo, five miles from Mineral City. Here take left fork in road to Jackson, seven miles over very poor, rough road; one mile below Jackson take right fork in road and follow sandy road, heavy going, to Montpelier, eleven miles. At Montpelier keep road to left and follow it to Glen Allen, where cross railroad tracks and get on pike again, twelve miles to Richmond. Three and one-half miles from Richmond pike becomes the Brook turnpike, with 20 cents' toll to pay, and road is then perfectly straight to Richmond, which enter straight and keep to Broad street, where turn left for Hotel Richmond.

Richmond is 314 miles from Washington, or, as you will go, including Luray, 343 miles. Gasoline can be obtained at the following places on the line: Leesburg, Woodstock, New Market, Luray, Harrisonburg, Staunton, Charlottesville, Gordonsville (probably), Louisa and Richmond.

Country people are kindly disposed towards automobilists, but expect and must receive consideration for horses, as many of the

A PRETTY GOOD FORD WHEN NEARING RICHMOND.

animals are spirited and badly frightened at the machine. Always stop at signal and help drivers, particularly women with horses. Horses prefer to be led past machine to having machine driven past them. Not much opportunity for speeding over thirty miles per hour anywhere, on account of teams, toll gates and turns in road; but scenery is very fine all the way and trip well worth taking. Total toll charges from Washington to Richmond, including ferriage and toll charges to Luray (not including Cavern fees), \$5.10.

A. C. A. TOUR TO JAMESTOWN EXPOSITION.

It is the intention of the Automobile Club of America to have a June tour to the Jamestown Exposition, limited to members of the club. The details will be announced shortly, and the route selected will be different from any one yet proposed. Chairman Waldron Williams of the Runs and Tours Committee, after consultation with Chairman Robert Lee Morrell of the Contest Committee, who is a New York State Commissioner of the Exposition, has about decided upon the Cape Charles route, which means that the run would be from New York to Philadelphia, to Cape Charles, whence ferry would be taken to Norfolk, the cars being carried on a freight transport and the tourists on a regular passenger boat. It is said that a fairly good road exists through the eastern shore of Maryland, and arrangements for a stopping place over night will be provided for by sleeping cars located at some point midway between Philadelphia and Cape Charles. The first night's stop would be in Philadelphia, the run there being 106 miles.

CROSSING A STRETCH OF SANDY ROAD NEAR WAVERLEY.

CLUBS PREPARING FOR THE SUMMER SEASON

Route for New Jersey Endurance Run Agreed Upon.

NEWARK, N. J., March 25.—At a full meeting of the special committee of the New Jersey Automobile and Motor Club, in charge of the plans for the three-day endurance run of May 30-June 1, held last Thursday evening, the route in detail was selected. One of the most important decisions arrived at during the meeting was the matter of controls. If satisfactory arrangements can be made, the noon stop will be made at Washington on the first day, at Trenton on the second day and at Lakewood on the third day. In addition to these, there will probably be an intermediate control on each day, both morning and afternoon.

The cars will leave the clubhouse at Broad and Chestnut streets on the first and second days of the run, and the clubhouse will also be the official finishing point on the first and third days. The route for the run up from Atlantic City to Newark on the third day was shortened somewhat in order that the cars may all arrive at the Broad street clubhouse in time for the reception which is to be tendered the participants in the tour. The route in detail follows:

First day—Newark, Montclair, Caldwell, Pine Brook, Parsippany, Whippany, Morristown, Mendham, Chester, German Valley, Port Colden, Washington (noon control), New Hampton, Junction, Glen Gardner, Clinton, Avondale, Mechanicsville, North Branch, Somerville, Bound Brook, Dunellen, Plainfield, Scotch Plains, Springfield, Hilton, Newark.

Second day—Newark, Elizabeth, Metuchen, New Brunswick, Dayton, Cranberry, Hightstown, Windsor, Edinburgh, Mercerville, Trenton (noon control), Bordentown, Columbus, Mt. Holly, Mechanicsville, Moorestown, Merchantville, Collingwood, Kirkwood, Berlin, Waterford, Hammonton, Elwood, Egg Harbor City, Pamoona, Absecon, Pleasantville, Atlantic City.

Third day—Atlantic City, Pleasantville, Absecon, Oceanville, Smithville, Pt. Republic, New Gretna, Tuckerton, Manahawkin, Barnegat, Waretown, Forked River, Bayville, Toms River, Lakewood (noon control), Lower Squankum, Freehold, Matawan, Old Bridge, New Brunswick, Metuchen, Rahway, Elizabeth, Newark.

Motor Boat Club of America Minstrel Show, April 10.

NEW YORK, March 27.—The minstrel show of the Motor Boat Club of America will be held in Madison Square Garden concert hall, Wednesday evening, April 10. The occasion will be "Ladies' Night" and an enjoyable occasion is looked for. The latter part of April a lecture will be given on the care and handling of motor boats, and in May a lecture on motor boat racing. Tickets for the minstrel show, except for the boxes, are not sold.

Quakeresses Have a Model Automobile Club.

PHILADELPHIA, March 25.—Organized just eleven weeks ago with thirteen members, the Ladies' Quaker City Motor Club already has sixty-five names on its roll, and by the time the charter list closes, on May 1, the Recruiting Committee promises that the one hundredth name will be added to the roll. In its rapid growth the club resembles its namesake—the Quaker City Motor Club—but the two organizations are entirely separate. Many of the members of the new club are wives, sisters or daughters of those composing the older organization—but that ends the relationship.

Application has been made for a charter, Attorney C. W. Talbot, of West Chester, having charge of the matter. The objects of the organization, as stated in the charter, read very much in the order of those which the sterner sex strive for when they form an automobile club—to promote track and road events, to

further sociability, to influence legislation favorable to motorists, etc. The constitution and by-laws are the joint work of the president, Mrs. Joseph J. Martin, and the secretary-treasurer, Mrs. Edward Beecher Finch (the latter president of the Women's Press Club). The other officers are: Mrs. Charles J. Swain, first vice-president, and Mrs. William Noblit, second vice-president. A board of ten directors, of which the officers named are members ex-officio, manage the affairs of the club. In forming the club the original

OFFICERS AND WELL-KNOWN MEMBERS OF THE LADIES' QUAKER CITY MOTOR CLUB.

Mrs. J. J. Martin, president; Mrs. Edward Beecher Finch, secretary-treasurer; Mrs. Chas. Swain, Mrs. William Nobles, vice-presidents; Mrs. Thomas Durham, Mrs. George Muller, Mrs. Aaron Mendenhall, Mrs. John Laird, Mrs. Charles Smirle, Mrs. William Trinkle, Mrs. Percy Chandler, Mrs. Hubert Reading, Mrs. Harry Cook, Mrs. Munyon, Mrs. Robert Pitts, Miss Nilson.

thirteen took no chances, but secured the services of ex-District Attorney Bell to coach them and see that everything was done in legal fashion.

Not to be outdone by mere men, the Quaker City ladies have secured quarters in the Majestic—a suite of three rooms, now nearing completion. The color scheme of the cozy home will be blue and gold—the club colors—and the fittings throughout will completely overshadow those of the home of the Quaker City men in the same building—and this despite the fact that the quarters of the men's club are a marvel of neatness and comfort. The new quarters will be thrown open to the members for the first time on Friday afternoon, April 8, when President Martin will entertain her friends at an informal reception. Later, at a date not yet decided upon, the husbands and fathers and brothers will be entertained. A surprisingly large proportion of the members can handle an automobile, and not a few of them own cars.

President Martin is now engaged in forming her committees, one of the most important of which is that which will prepare a schedule of runs, a gymkhana and other events.

A peculiar feature of the club's affairs which Secretary-Treas-

THE AUTOMOBILE CALENDAR.

AMERICAN.

Shows.

- April 1-6.....—St. Louis, Mo., Automobile Show, Jal Alal Building, St. Louis Automobile Dealers' Association.

- August 1-7.....—Criterion of France, 1,750 Miles Touring Competition and 250-mile race for the Press Cup, A. C. of France.
- August 11-29...—France, Coupe de Auvergne.
- Sept. 1.....—Italy, Brescia Circuit, Florio Cup, A. C. of Italy.

Motor Boat Races.

- April 2-15.....—Monaco Motor Boat Exhibition and Races.
- April 15-30.....—Nice, Motor Boat Races.
- June 15-23.....—Kiel (Germany) Motor Boat Races.

urer Finch commented upon to THE AUTOMOBILE representative was the insistency with which the number "13" projected itself into the club's deliberations. There were 13 at the temporary organization, 26 at the permanent organization, 39 at the fourth meeting, 52 at the meeting on March 13, and 65 on the roll now—all multiples of 13. Nothing daunted, however, the Quakeresses propose to strive onward and upward, leaving superstitious worries to those who can be affected by coincidences of the kind.

New York Motor Club Plans an Elaborate Orphans' Day.

NEW YORK, March 26.—Orphans' Day will again be the leading event on the calendar of early summer outings of the New York Motor Club. This was decided upon at the last meeting of the board of directors, and a committee was appointed consisting of S. A. Miles, chairman; W. J. Morgan and R. G. Howell, with power to select associates, to conduct the run. The date has not yet been selected, but it will probably be the latter part of May or early in June. It is planned to have this year's Orphans' Day eclipse in importance and its benevolent objects the two previous yearly runs conducted by the club, and a concerted effort will be made to provide ample accommodations for the transportation of all the children.

It was definitely decided at the recent directors' meeting that the club should own a home of its own, and steps were taken to secure a site in the vicinity of the Grand Circle at West Fifty-ninth street. Plans were adopted for the financing.

English System for Worcester Hill Climb.

WORCESTER, MASS., March 28.—Worcester will have its third annual automobile hill climb on Dead Horse hill here in May, the date to be announced later. It will be under the auspices of the Worcester Automobile Club, as the others have been. For the first time in America the new English system of handicapping probably will be employed. The system is now being earnestly discussed, and is generally favored by members of the Worcester club. If it is put into operation, it will be the first time a meet in America has been so conducted, and its success or failure will be awaited with interest. By the English system only one event is run, all cars participating by an equitable system of handicapping. By plotting the curves in advance there is little to do except see that the contestants give correct data, figure the elapsed and corrected times, and announce the results.

Chicago Ladies Form a Motor Club.

CHICAGO, March 27.—The Windy City has an automobile association in which the mere man plays no part. It bears the title of the Chicago Women's Motor Club, is blessed with all the vigor of youth, and has just held an informal meeting, followed by an adjournment for tea at the Lexington Hotel. The ladies will hold a floral parade in May. The officers are: President, Mrs. C. H. Foster; vice-president, Mrs. A. F. Chase; treasurer, Miss A. M. Andrews; secretary, Mrs. N. J. Boardman.

Quakers Must Change Date of Their Hill Climb.

PHILADELPHIA, March 25.—Continued opposition to permitting the Quaker City Motor Club to run off its hill climb on City Line on Memorial Day has forced the Contest Committee to change the date to May 25 or June 1. An effort will be made to get a permit for either of the Saturdays mentioned, failing which City Line will be abandoned and one of the other courses taken up.

Globe-Girdler Glidden Relates Experiences to Buffalonians.

BUFFALO, N. Y., March 26.—Charles J. Glidden, donor of the Glidden trophy, delivered an interesting address last Friday night to the members of the Automobile Club of Buffalo and their friends. Most of the talk related to sights seen in the Far East and many funny experiences in China and Japan were mentioned. Stereoscopic views were shown by Dr. C. E. Cummings.

Legislative Mills Are Not So Obnoxiously Busy.

Though the time when every State Legislature does not feel it incumbent upon itself to propagate and attempt to pass a number of bills every year is still far in the distance, signs are not wanting that things are at least tending in that direction. That such a state of affairs must ultimately come to pass, anyone who wishes to look but a decade cannot fail to realize. Long before the bicycle had tumbled from the extreme heights of favor to which it had been boosted, the thousand and one laws and municipal ordinances with which every statute book the country over was loaded had practically passed into oblivion. So far as their actual legal force and effect went, they were as operative as the day they first received the sanction of the all-wise bodies that had formulated them—in reality, the ducking stool and the stocks were not more dead than they.

In the fullness of time much of the legislation that is now thought to be a crying necessity for the proper restriction of the new method of locomotion and its owner will have been relegated to the same category. Laws there will always be, but it will no more be thought necessary to make them more burdensome at every opportunity than is now the case with the bicycle. The automobile is settling down more and more into the daily life of a constantly increasing proportion of the population, and long before it becomes universal, if any institution can ever really be accorded that quality, the necessity for making its possession as onerous a burden as possible will no longer be apparent, even to the Solons who guide our destinies from afar. As to the present signs of encouragement, we may be deceived. It is quite

possible that these same gentlemen may have been so attentive to other and more profitable fields of legislation that for the moment the automobile has been relegated to a second place. It will be there when wanted again. Whatever the cause, there certainly has been a slowing up of the legislative mills all over the country; there has been less legislation and less attempt to make it drastic than ever before. For that much let us be thankful, and at the same time be appreciative of the successful efforts of several State associations of the American Automobile Association in assisting in the general discouragement of too much legislation.

Passing of the Quickly Assembled Car.

There is one thing for which the automobile industry as a whole can never be too thankful for, and that is the fact that it has never experienced an out-and-out boom. One of those huge bubbles of simulated prosperity that swell to immense dimensions in a short time, and, bursting, leave an entire industry prostrate. A combination of circumstances, coupled with the wise foresight of those behind the representative organizations of manufacturers which entered the field so early in the history of the industry, sufficed to prevent any such calamity. To be of any value an automobile must be well built, of good materials—factors that do not lend themselves to the rapid production of cars without a large outlay of capital and a well-perfected organization, backed by brains and executive ability.

Not that this has prevented the attempt—quite the contrary; 1903 witnessed the closest approach to a boom that the industry has ever suffered. Motors were bought in one place, bodies in another, and in this manner the components of a car were collected and put together under conditions and with the aid of facilities about on a par with those at the hand of the average amateur mechanic who has a workshop in his barn. Fortunately the influences referred to were strong enough to successfully combat this flurry, that bade fair to flood the market with worthless junk. Not that it is intended to belittle the assembled car as such. There is probably not a factory to-day on either side of the Atlantic that attempts to turn out the complete automobile. In a few instances in this country every part of the machine and its accessories that can be profitably turned out in one factory are produced, but there must always be many things which the specialist is far better fitted to manufacture. Doubtless there are more assembled cars on the American market to-day than ever there were, but most of them will be made in their own factories within the next two years or less. Many of the best known cars were assembled but a few years ago, but one by one they have achieved homes of their own in the sense that they are now turned out as far as possible by their makers, and it is this constant passing of the assembled car that is one of the best guarantees of the industry's solidity.

The Degree of Bachelor of Automobiling.

Indicating unmistakably the rapid growth of automobiling is the attitude of the leading universities in beginning to give special attention to a subject of widespread interest and the greatest value to the welfare of the country, for it means the solving of quick transportation for the individual in and about cities and towns and even across States and into foreign countries. Add to this the distribution of all kinds of freight and business traffic, and the magnitude of the automobile industry approaches a degree second to none in the development of the republic. There will also be added to the curriculum of the colleges a department on roadmaking and the graduating of experienced roadbuilders, for the improvement of the highways inevitably follows in the wake of the motor-driven vehicle. Even now a Pacific Coast university is to add a course on roadbuilding, providing its State legislators are agreeable, which seems to be assured in advance.

IN NEW YORK'S LEGISLATIVE MILL.

ALBANY, N. Y., March 25.—Assemblyman Young's bill for the insurance of automobiles has been unsatisfactory to the Senators, and they have had it amended and reprinted twice, and it is now on the third reading calendar of the Senate. The new section to be added to the insurance law now allows insurance companies to be formed to issue policies as follows: "Against loss or damage resulting from accidents caused to or by a vehicle, conveyance, or duly licensed automobile, either to the vehicle, conveyance or automobile itself or to any other property." The amendment makes it more than an auto insurance law, and takes in all other vehicles. It is expected to pass the Senate this week, and as amended will have to go to the Assembly for concurrence before it can be sent to the Governor.

The Brough impounding of motor vehicles has been changed by a substitute bill, and the new amendment relative to the giving of security, either cash, guarantee bond, or machine in case of arrest and the addition of an impounding section for the retention of a machine left for bail, is now back in the general laws committee.

MISSOURI BILL AWAITING SIGNATURE.

JEFFERSON CITY, Mo., March 25.—What is known as the House Substitute bill, having been passed by both houses of the State Legislature, is now in the hands of the Governor, awaiting his signature to become a law. Its chief features are the provision of a \$5 registration fee, payable to the Secretary of State, and a speed limit in the open country of fifteen miles. Three-inch numbers and lights are required, besides which the autoist is hedged around with a cordon of regulations regarding coming to a halt and also stopping the motor at the beck of a driver of horses. It was attempted to cut the speed limit down to ten miles, but Senator Peck, the only member of the Senate who owns a car, then proposed that a further amendment permitting automobiles to keep up with funeral processions be added. The speed-reducing amendment was lost by an almost unanimous vote.

TO MEET A FUTURE CRY FOR ROADMAKERS.

SEATTLE, WASH., March 25.—One of the results of the good roads movement in this State is an effort that has just been launched to have appointed to the faculty of the State University an instructor in highway building. The officers of the State Good Roads Association are advocating this very strongly, and urging that a man of national reputation be secured. In a measure the present effort is due to Samuel C. Lancaster, consulting engineer, Department of Public Highways, who has been spending the past few months here, and speaking on the subject of good roads in various sections of the State. He maintains that there is a great future for the expert road builder.

PERTH AMBOY BRIDGE RECONSTRUCTION.

As a result of the closing to traffic of the bridge across the Raritan river between Perth Amboy and South Amboy, N. J., no automobile tour can be scheduled across Staten Island to North Jersey coast points except by the long detour via Metuchen and New Brunswick, thus adding twenty-four miles. All traffic over the bridge will be suspended probably until mid-summer, it being estimated that the replacement of the present span with one satisfactory to the War Department will require that length of time.

C. P. MALCOLM, TWO-CYCLE ADVOCATE, ILL.

C. P. Malcolm, of Detroit, Mich., the well-known advocate of the two-cylinder engine, is reported to be very ill at the present time, and it is probable that nothing more will come from his pen for the next few months. His early recovery is hoped for by the many who have read his articles, even though all do not entirely agree with him.

AUTO ENGINEERS TO HAVE SUMMER MEETING.

The Society of Automobile Engineers will hold a three-day summer meeting at Buffalo on dates to be selected later, but between July 20 and August 10. This was decided upon at a session held Saturday night last in the Flatiron Building, New York City. One of the three days will be devoted to visiting the several large automobile plants in Buffalo. The committee in charge of arrangements consists of T. J. Fay, Henry Hess and H. M. Swetland.

President A. L. Riker announced that the society had been recognized as a permanent engineering society by the American Society of Mechanical Engineers, and therefore there would be an exchange of papers between the two organizations.

A publication committee to take charge of all papers for publication was appointed, consisting of H. F. Donaldson, H. F. Towle and A. L. Clough.

NEW HAVEN'S SUCCESSFUL SHOW.

NEW HAVEN, CONN., March 28.—The automobile exposition held the past week in the Second Regiment Armory has been most successful. It was under the auspices of Troop A, Cavalry, and the management of William E. Dobbins. Crowds thronged the exposition hall the entire week.

Among the automobiles shown were: Franklin, Knox, Babcock, Locomobile, Bailey, White, Autocar, Springfield, Continental, Buick, Thomas, Jackson, Cadillac, Haynes, Rambler, Royal Tourist, Elmore, Logan, Bowers. Also exhibiting: Motorcycle Co., Colonial Rubber Tire Co., Crescent Automobile Supply Co., Sanford Motor Co., New Haven Auto Supply Co., Maley Motorcycle Co.

As an outcome of the show the dealers formed an organization to be known as the New Haven Automobile Association. These officers were elected: President, Cowles Tollman, of the Holcomb Automobile Company; vice-president, W. A. Maynard, of the Thomas agency; secretary and treasurer, Walter A. Crousell, of the New Haven Automobile Corporation.

ONE-THIRD OF A CENT A MILE PER PASSENGER.

From 200 owners of single-cylinder Cadillacs, the Cadillac Motor Car Company announces that it has received affidavits which demonstrate thoroughly that the average cost to them for maintaining their cars has been about \$2.50 per month, the terms of use running all the way from one to four years. This makes the average cost per mile one and one-third cents per car, or an average of only about one-third of a cent per mile per passenger. These average costs are based on the expense of gasoline, oil, repairs, etc., and in some cases including tires. The Cadillac company calls attention to the fact that these 200 owners are scattered all over the United States and not a few isolated cases. In some of its current advertisements in trade papers, including THE AUTOMOBILE, the Cadillac company is calling attention to its interesting series of advertisements.

ROYAL AUTO CLUB TO OCCUPY WAR OFFICE.

LONDON, March 19.—For the second time within five years the Automobile Club of Great Britain and Ireland, now called the Royal Automobile Club by command of King Edward, has been obliged to remove owing to cramped quarters. The clubhouse at 119 Piccadilly will very shortly be vacated in favor of the old War Office building in Pall Mall, until quite recently occupied by the Government.

In a lecture before the recently organized Motor Club of the West Side Y. M. C. A., Monday night, Augustus Post said: "The relation between the automobile and practical flying machines is very close, and it is an interesting fact that several automobile manufacturers are now devoting particular attention to the making of light motors of fairly high horsepower for aerial use."

INDIVIDUALITY IN GRAND PRIX.

There will be more variety of design in the racing machines to compete for the French Grand Prix on July 2 than is usually found in European contests of this nature. French constructors give little intimation of what they will produce for the big event, but from private inquiries it is pretty certain that the machines will be similar in general design to those of last year, with improved and more economic carbureters and more efficient transmission. There will be a greater proportion of shaft-driven machines than ever before. Great Britain, Belgium and the United States depart most widely from the beaten track.

D. M. Weigel, who with Lee Guinness will form the British team in the race, is building a couple of eight-cylinder racers which are bound to attract attention. The cylinders are in one line, the engine being 90 inches from end to end. The accompanying engraving shows Mr. Weigel, who is 69 1-2 inches in height, holding up what is declared to be the longest crankshaft ever made. It is estimated that the Weigel racers will be capable of a speed of ninety miles

D. M. WEIGEL.

an hour. The three Belgian racers entered by the firm of Germain will be lightweights, developing 75 horsepower.

Walter Christie, the sole American representative, displays his individuality by entering the only front-drive machine in the race, and the only one of this type to compete on European soil.

THE VANDERBILT CUP RACE.

According to A. R. Pardington, general manager of the Long Island Motor Parkway, the Vanderbilt Cup race will certainly take place on the eastern section of the parkway, the construction of which will begin first. There will be a straightaway stretch of eight miles or more with wide loops at each end, and the grandstand will probably be located near the easternmost loop. With a road fifty feet wide it will be possible for cars to be driven at the limit of speed in both directions. Probably a whitewashed line will divide the road into two parts. It is expected that the racing section will be ready for use by September 1.

William K. Vanderbilt, Jr., will return from abroad next week, and soon after Chairman Jefferson DeMont Thompson will call a meeting of the A. A. A. Racing Board. Mr. Thompson has recovered from his recent illness.

Two Dragon Cars for Vanderbilt Race.

Announcement is made through John Kane Mills, president of the Dragon Automobile Company, that there will be two 110-horsepower four-cylinder Dragon racers in the American Elimination Trial of the Vanderbilt Cup race. It is further stated that the cars are well under way and will be ready for road trials early in August.

Ernest Kelly May Be a Thomas "Cup" Pilot.

PHILADELPHIA, March 25.—A possible pilot of one of the Thomas cars in the next Vanderbilt Cup elimination race is Ernest R. Kelly, who was little heard of until he landed the Flyer at the top of the non-stop heap with a record of over 21 days' continuous running, but who nevertheless has done much creditable track and road work. Kelly is at present managing the local Thomas agency of Marvin & Hart and is keeping in trim by a little occasional fast work on the suburban roads.

HOTCHKISS AT ROCHESTER BANQUET.

ROCHESTER, N. Y., March 25.—The seventh annual banquet of the Rochester Automobile Club was held to-night at the Genesee Valley Club. Covers were laid for 110 diners. In a decidedly unique manner the repast was served. Cocktails were drunk in oil cans, consomme in Mobiloil cans, while the ice cream was brought to the table in Albany grease cans, regulation size. The menu cards had a front cover showing an automobile speeding along at twilight, with a beautiful cloud effect on the horizon. The picture was framed with automobile tires, and the back cover represented an auto wheel and tire.

President H. S. Woodworth introduced Special County Judge John A. Barhite as toastmaster. The first speaker was William H. Hotchkiss, of Buffalo, president of the American Automobile Association, and he spoke convincingly on the necessity for a national organization. President Hotchkiss took occasion to compliment the Rochester club on its loyal support of the A. A. A. through membership in the State body.

John J. McInerney, George A. Carnahan, J. J. Mandery and J. E. Gleason were other speakers. All of them referred to the coming of a better understanding between the autoists and other users of the road when each respected the rights of the other. Then legislation would become small in quantity.

The club held its annual meeting Monday afternoon. The following officers were elected: President, H. S. Woodworth; vice-president, H. G. Strong; secretary and treasurer, Bert Van Tuyle; attorney, John A. Barhite; consulting engineer, A. J. Rockwood; directors, W. C. Barry, Jr., F. E. Mason, Lee Richmond, Rudolph Schmidt, Griff D. Palmer, J. S. Bingeman, F. H. Bettys, A. F. Crittenden and A. J. Rockwood.

THE COMMITTEES OF THE A. M. C. M. A.

Chairman Benjamin Briscoe of the Committee of Management of the American Motor Car Manufacturers' Association has completed his list of committees for the ensuing year, interest centering upon the Show Committee, which is first given in the list. Following are the complete committees:

Show Committee—H. O. Smith, Premier Motor Manufacturing Company, chairman; William Mitchell Lewis, Mitchell Motor Car Company; J. B. Bartholomew, the Bartholomew Company.

Tours and Races—W. C. Marmon, Nordyke & Marmon Company, chairman; V. A. Longaker, American Motor Car Company; F. M. Keeton, De Luxe Motor Car Company; John Dolson, Dolson Automobile Company; E. K. Conover, Conover Motor Car Company.

Good Roads—Charles Lewis, Jackson Automobile Company, chairman; James Couzens, Ford Motor Company; John Kane Mills, Dragon Automobile Company.

Legislation—R. E. Olds, Reo Motor Company, chairman; Sidney Breese, B. L. M. Motor Car & Equipment Company; George C. John, St. Louis Car Company.

Membership—W. H. Van Dervoort, Moline Automobile Company, chairman; Morris Grabowsky, Rapid Motor Vehicle Company; Jesse French, Jr., St. Louis Motor Car Company.

Advertising and Publicity—Charles E. Duryea, Duryea Power Company, chairman; G. B. Louduback, Buckeye Manufacturing Company; F. M. Keeton, De Luxe Motor Car Company.

Finance—James Couzens, Ford Motor Company, chairman; R. G. Harrison, Harrison Wagon Company; L. C. Boyd, Marlon Motor Car Company.

Standardization and Technical—John D. Maxwell, Maxwell-Briscoe Motor Company, chairman; Charles E. Duryea, Duryea Power Company; Henry Ford, Ford Motor Company; R. B. Crawford, Crawford Automobile Company; L. P. Mooers, St. Louis Motor Car Company; R. E. Olds, Reo Motor Car Company.

Weight and Transportation—W. G. Morley, Aerocar Company, chairman; Harry Knox, Knox Motor Truck Company; S. H. Mora, Mora Motor Car Company.

Tires—William Mitchell Lewis, Mitchell Motor Car Company, chairman; James Couzens, Ford Motor Company; J. B. Bartholomew, The Bartholomew Company.

Agencies—Roger J. Sullivan, Wayne Automobile Company, chairman; W. H. Van Dervoort, Moline Automobile Company; George C. John, St. Louis Car Company.

GROWTH OF A. A. A. IS RAPID.

Directors of the American Automobile Association are very much in evidence in New York City this week. Yesterday at the club rooms of the Automobile Club of America, West Fifty-fourth street, was held a session of the entire Board of Directors, with President William H. Hotchkiss in the chair. Earlier in the day Chairman Charles Thaddeus Terry had a meeting of the Legislative Board at the Manhattan Hotel, and at about the same time Chairman Robert P. Hooper was presiding at a meeting of the Good Roads Board, held at the offices of the Long Island Motor Parkway. Chairman Frank B. Hower, of the Touring Board, made a report at the afternoon meeting of the Board of Directors, when the annual A. A. A. tour came in for much attention.

The Minnesota State Automobile Association and the Connecticut State Automobile Association were admitted to active membership, and it is understood that Michigan, Wisconsin, Missouri, Kentucky, Maryland, and Indiana are nearly ready to apply for affiliation. Secretary Frederick H. Elliott recently made a very successful recruiting tour of the Middle West. The Hotchkiss administration is the most energetic in the history of the A. A. A., and it is expected that before the year is over the national organization will have a membership of over 20,000.

Connecticut State Automobile Association.

HARTFORD, CONN., March 25.—The Connecticut State Automobile Association of the A. A. A., consisting of the Bridgeport, Hartford, and New Britain clubs, has been organized with the following officers: President, Hon. George M. Landers, New Britain; vice-president, F. T. Staples, Bridgeport; secretary and treasurer, G. K. Dustin; attorney, Walter S. Schutz, Hartford.

Minnesota State Automobile Association.

MINNEAPOLIS, MINN., March 25.—These are the officers of the Minnesota State Automobile Association, which has applied for membership in the A. A. A.: President, Frank M. Joyce, Minneapolis; vice-president, George M. Palmer, Mankato; secretary and treasurer, H. S. Johnson, St. Paul. The Minneapolis, St. Paul, Duluth, and Mankato clubs comprise the State body, which has a total membership of nearly a thousand.

Michigan to Have an A. A. A. State Body.

DETROIT, MICH., March 25.—Michigan representation in the American Automobile Association is assured as the result of a visit to this city of Secretary Frederick H. Elliott, of the A. A. A. Mr. Elliott has been on a Western trip in the interests of the association, and made his first stop at Detroit. From here he went to Milwaukee and Minneapolis. Three clubs are necessary for a State organization. It was Secretary Elliott's purpose to interest the Automobile Club of Detroit, as the Grand Rapids and Saginaw clubs already have membership in the A. A. A. While here Mr. Elliott met President E. S. George and Secretary Harry Skilman, of the local organization, Paul Deming, and James H. Flinn. J. J. Jackson was also on hand, while the Saginaw club sent notice of its accord.

As a result of the conference the Detroit Automobile Club met Thursday evening, when it was decided to act on the matter of obtaining A. A. A. membership, preliminary to the move for formation of the State organization. The three clubs already mentioned will form the nucleus, and it is expected that Kalamazoo, Battle Creek, Jackson, and Muskegon will be represented after the move is fairly underway.

Governor Folk, of Missouri, has been requested by a number of good roads advocates of his State to do all in his power to prevent the future use of convicts by labor contractors. The good roads advocates hope that the State Legislature will pass a measure authorizing the employment of convicts in the building of two main State roads.

ANNUAL OF N. Y. STATE ASSN.

The annual meeting of the New York State Automobile Association, held at Auburn, N. Y., Thursday, March 21, resulted in a general demand for the continuance of Oliver A. Quayle, of the Albany Automobile Club, as president of the organization. Mr. Quayle, as chairman of the Legislative Board, has kept a keen eye on the numerous automobile measures introduced in the New York State Legislature, and it appears probable from present indications that the existing law will continue in effect without any changes. H. S. Woodworth, of the Rochester Automobile Club, was also re-elected to the first vice-presidency; N. M. Pierce, of the Binghamton Automobile Club, to the treasurership, and C. D. Hakes was unanimously continued in the secretarial position.

OLIVER A. QUAYLE, President New York State Automobile Association.

The New York State Association has a membership of twenty clubs, including the Cohoes Automobile Club, admitted at the Thursday meeting, and about 3,700 members. Its policy has been to ask nothing unreasonable, and at the same time it has vigorously and successfully contested against oppressive measures.

The Auburn session was attended by the following: President Oliver A. Quayle, Secretary C. D. Hakes, Albany Motor Club; Treasurer N. M. Pierce, Binghamton Automobile Club; S. M. Butler, Emerson Brooks, Automobile Club of America; W. H. Van Auken, Utica Automobile Club; F. B. Hower, A. H. Knoll, D. H. Lewis, Automobile Club of Buffalo; S. C. Tallman, Auto Club of Auburn; A. G. Batchelder, New York Motor Club.

The reports presented showed the State Association to be in a very prosperous condition, with a healthy treasury and a growing membership. Plans were outlined for further increasing the value of the organization to the automobilists of the State.

Following the business session the Automobile Club of Auburn gave a dinner to the directors at the City Club, where the meeting was held. Charles J. Glidden, the "globe-girdler," was the guest of honor, and later in the evening he gave an illustrated lecture for the benefit of the Auburn City Hospital.

THAT OLD LICENSE OF THE SEARCHMONT CO.

The license of the Searchmont Automobile Company, granted by the Association of Licensed Automobile Manufacturers, was canceled in 1904, the Searchmont company having become bankrupt and failing to pay the royalties required by the license. The trustees of the Searchmont Automobile Company, through its attorneys, recently argued in the Supreme Court before Judge Leventritt asking for opportunity of securing from the books of the Licensed Association all data from March 5, 1903, up to the present time, basing its right upon the claim that its ousting was illegal and that it would prove, through access to the desired reports, that several other members of the association had not settled for royalties. The legal department of the A. L. A. M. designates the suit as a "fishing expedition," and assert that back of it is the American Motor Car Manufacturers' Association. The case is scheduled to be tried the first Monday in April.

Charles J. Glidden, the donor of the trophy cup bearing his name, was in Chicago, Wednesday, as the guest of Ferdinand W. Peck. A dinner was given in his honor at the Calumet Club, when prominent Chicago automobilists exchanged ideas.

R. G. KELSEY, IN HIS MATHESON, STARTING THE RUN.

FROM NEW YORK TO BOSTON IN WINTERTIME.

By R. G. KELSEY.

Half-past five on a March morning is, after all, an uninviting time. When we left the New York garage with our ordinary stock Matheson car it was dark and cold and gloomy, but by the time we had drawn up at the place where the starters were waiting for us it was becoming light enough to distinguish the road easily. It was 6:30 o'clock when we officially started out Jerome avenue.

New Rochelle was reached without incident, but near Stamford Station we had a skid which brought us closer to a telegraph pole than was really comfortable. Bridgeport was reached at 8:15 A.M., the 62 miles having been covered at a fraction under thirty miles an hour. It required sixty-five minutes to reach New Haven, 21 miles beyond, and here we got our first taste of the mud and snow which were going to prove such a deterrent.

At New Haven we swung northward and passed Meriden, 20 miles away, in 55 minutes. An hour later saw us in Hartford, and here twenty-five precious minutes were lost in trying to find some one in town who knew whether the east or the west bank of the Connecticut river afforded the better roads. Up the long hill outside the city we plowed, sometimes on first, mostly on second, speed, through mud that averaged more than eight inches in depth; no wet mud, either, but the soft, sticky, hold-fast kind, which the anti-skid chains picked up and threw high in the air behind us. Two hours and twenty-five minutes it took to cover the twenty-seven miles to Springfield. Here another twenty-five minutes was taken for replenishing our gasoline tank, and also filling the cavity in our own systems occasioned by the lack of food from 5 A.M. until nearly 2 P.M.

At 2:10 we left Springfield, being warned that the roads ahead of us were in frightful condition. However, the first fifteen miles to Palmer were very satisfactory, and that town was reached in forty minutes. Here another delay occurred, occasioned by our getting off the road, and after circling around for over half an hour we found ourselves in the same place from which we started.

From Palmer eastward the roads were alternately snowbanks and mudholes, the conditions sometimes varied by occasional stretches of glaring ice, on which the car swung and slewed. Catastrophes, however, were averted and we reached Worcester finally at 5:20. From Worcester into Boston, forty-eight miles, we had hoped for better things, but our hope was doomed to disappointment. The twenty miles which separate Worcester from Marlboro were the worst of our trip, and our time was so slow that we began to wonder if we ever would see the lights of Boston. From Marlboro—which we left at 7:30—into Boston the conditions steadily improved, and when at length we saw the glittering lights on the Capitol as we swung down Commonwealth avenue we felt that we had indeed come to the end of our journey. The city limits were passed at 7:50, and we drew up in front of the Horticultural Hall at 8:15, our total elapsed

time being 14 hours.5 minutes, beating the best previous time made during Boston show week by over five hours.

Outside of our gasoline and oil, the expense of our trip amounted to five cents, with which we purchased some extra belt fasteners—more as a matter of precaution than of necessity. Our total consumption of gasoline for the entire 251 miles which the odometer showed we had covered was 25 1-4 gallons, our oil consumed being 2 gallons.

PLANS FOR THE MICHELIN AMERICAN FACTORY

Edouard Michelin, of Paris, who had been in this country for several months past quietly arranging for an American company and factory, has returned to France. It is known that M. Michelin visited several well-known American tire factories and obtained a very comprehensive idea of the tire industry in this country before he completed the plans for an American Michelin plant, which it is understood will be located at Milltown, N. J. M. Michelin gives the following history of the parent company:

"The Michelin factory was erected in 1832 at Clermont Ferrand, France, by the grandfather of André and Edouard Michelin, these two brothers taking over the plant in 1888. In 1891 only fifty-two employes were kept busy, and it was in this year that the Michelin detachable bicycle tire was used by the winner of the first Paris-Brest race. In 1896 the first Michelin automobile tire appeared and now the company employs 4,000 men.

"We are coming to the United States because, notwithstanding the fact that we have to pay an enormous duty, we sell here a large quantity of tires. Our own representatives in this country, E. Lamberjack & Co., last year sold over 16,000 tires and have already contracted for 20,000 tires for this year.

"Some have said that Michelin tires could not be made as well in America as they are in France. I have heard this from several American citizens and confess to have been rather surprised at it. I do not pretend to judge America after the one month I have been here, but I can say, however, that I feel a deep admiration for the United States. I consider that everything here is great and great are the minds of your business men. Everybody seems to go ahead with no fear of danger. Our French and American factories will compete, good-naturedly, and this competition will be very useful to the progress of tires. I am rather at a loss to say which one will overcome the other in popularity, but I think the combination of French ingenuity and American brains will prove a great success."

On the Wednesday evening of last week, preceding his sailing the following day on the Touraine, M. Michelin was the guest of honor at a complimentary dinner given to him at the Café des Beaux Arts. Those present included Paul Lacroix, manager of the Renault Frères American branch; George B. Van Cleve, head of the advertising agency of the same name; Leon Rubay, he of the many ignition specialties, and S. H. Stern, American manager of E. Lamberjack & Co.

AN UP-TO-THE-MINUTE MICHELIN POSTER.

A few years ago Michelin created Bibendum, a giant made of automobile tires, whose quality was that he could drink everything. "Bibendum boit l'obstacle"—"Bibendum drinks up the obstacle"—has become a household phrase in France. The exclamation of the drunkard as in his wild dream he watches Bibendum at work on the wine barrels is "Lucky beggar."

WAYNE MODEL N RUNABOUT

THERE is little doubt that the so-called high-powered runabout is something that is being carried to extremes in a few instances, but the fact that this is the case can do no more to detract from its well-deserved popularity along proper lines than the reckless use of the touring car on the part of a few irresponsible chauffeurs does to the automobile generally. In designing their gentleman's roadster the makers of the Wayne cars have carefully avoided extremes in either direction, and the result is not alone a highly attractive looking car, but one that aptly reflects the purpose for which it is intended. It is equipped with a 30-35-horsepower motor and in general contour follows the lines of the touring Model N, of the same builders, which will be apparent from the photograph of the complete car forming the head of the page.

Stripped of the body, the chassis itself reveals an equally clean-cut appearance, as will be apparent from the accompanying illustration of it. The motor is representative of the most approved trend of current practice in its class. All the valves are placed on the same side and operated from a single camshaft, the valves themselves being made with nickel-steel heads and machine steel stems, electrically welded together, while long flanged wrought-steel guides are pressed into the openings in the base of the valve ports. The wrist pins are one-inch pieces of solid steel, fastening by tilt screws and wire retainers

to the ends of the connecting rods. The latter are of the marine type and are drop forgings of high-grade steel. Throughout the design of the motor the matter of accessibility has been considered paramount, so that every part of it is readily reached for adjustment or repair, without the necessity of tearing down a number of other parts.

The change-speed gear, which is operated by the selective type of gear shifting, provides three speeds forward and reverse and is advantageously located on the rear axle, together with the bevel driving gears and differential, all of which are contained in the same housing. This permits of a style of rear axle construction that lends itself most readily to the requirements of simplicity, coupled with the maximum strength, beside making the gear box accessible to a degree seldom realized where it is placed under the center of the body. Between the clutch and the change-speed gear box there is a shaft slightly over three feet in length, the latter tending materially to reduce the angularity, the entire power plant and transmission mechanism, including the rear axle, being practically in the same horizontal plane under normal conditions, which mean with the customary load, with but a variation of two and one-half degrees as the extreme pitch when the car is empty. The body is of steel and aluminum, and is provided with a third or rumble seat, which, however, is readily detachable to provide accommodation for a trunk, when desired.

H. C. KERR'S ORIENT WINNER IN HONOLULU PARADE.

A HONOLULU FLORAL PARADE CAR.

Given a Honolulu environment, artistic skill and the expenditure of not a little cash, and the metamorphosis of the automobile is an accomplished fact. In this interesting process the auto has an advantage over the horse vehicles, for the latter, however much they may be buried under flowers and foliage, are obliged to retain their quadrupeds to conserve their mobility. The accompanying illustration depicts H. C. Kerr's Orient buckboard in the Honolulu annual floral parade. No mechanical means of propulsion being visible, the graceful bird looked like a thing of life as it quickly skimmed along in the procession of autos.

A DECREASE OF SIXTEEN PER CENT.

(From the European Edition of the "Herald.")

A decrease of 16 per cent., as compared with last year, is noted in the exportation of French automobiles during January.

FREDERICK GLASSUP IMPORTS A BRITANNIA.

The first Britannia automobile to be imported into this country is an 18-24-horsepower four-cylinder touring car and has a number of features worthy of special notice. Among these are: A silent rotary pump of novel design, new automatic carbureter, water piping of extra large size, powerful internal-expansion foot and hand brakes, and circular honeycombed radiator with improved fan. The gear box is of a sliding pattern with three speeds and solid bearings. This car is made by the Britannia Engineering Company, Ltd., of Colchester, Eng., contractors to the British Admiralty, War Office and India Office, and is consigned to Frederick Glassup, the company's sole representative in America.

STATEMENT BY THE JONES SPEEDOMETER.

From the Jones Speedometer, 127 West Thirty-second street, New York City, comes the following communication:

The employees in the toolmaking department of the Jones speedometer factory at New Rochelle, N. Y., went out "on strike" Thursday, March 15. Their places were promptly filled by the Metal Trades Association, of which we are members, and practically all the tools needed for the manufacture of 1907 models have been completed. We desire to inform the public and the trade that there will be no curtailment, interruption, or material delay in our production, and that our customers may positively rely upon the continued prompt shipment of all orders.

THE JONES SPEEDOMETER,
G. L. Holmes, Manager.

TO BE AN A. A. A. TOUR CONTESTANT AGAIN.

E. R. Lozier, who participated in the 1906 A. A. A. tour with a 40-horsepower Lozier, again will be a contestant in the A. A. A. event for the Glidden trophy. Preliminary to the national tour, Mr. Lozier and several of his friends are going to have a run between New York and Cleveland, the best performer to be the winner of a special cup intended to settle several discussions which have arisen during the past winter.

IN THE ASSEMBLING ROOM OF THE E. R. THOMAS DETROIT COMPANY, DETROIT, MICH.—THE ASSEMBLING STANDS WERE DESIGNED BY VICE-PRESIDENT F. E. COFFIN.—FOUR CARS PER DAY IS NOW THE REGULAR OUTPUT

BRIEF ITEMS OF NEWS AND TRADE MISCELLANY

The Reliance motor truck has just been designated as an official baggage truck for the A. A. A. tour for the Glidden and other trophies.

About April 1 the C. G. V. Import Company will remove from their present premises on West Sixty-ninth street to its new showroom at 1849 Broadway

Albert H. Funke, dealer in guns and automobile supplies at 83 Chambers street, New York City, has filed a petition in bankruptcy with liabilities of \$102,338 and assets of \$51,700.

At the Boston show a woman who called at the Corbin exhibit, said: "I want a car that will always have a home; the last car we bought went out of business and consequently had no home, so it was almost impossible to secure any duplicate parts to make repairs, which was a great disadvantage."

C. W. Kelsey, general manager of the newly-formed American Cab and Express Company, which will shortly inaugurate the taximeter cab system in several large cities, has just returned from Chicago, where he has made satisfactory arrangements for the branch of the company in that city. Mr. Kelsey is satisfied that taximeters will be in public demand as much in Chicago as in New York.

Alexander Winton, Geo. H. Brown and Chas. B. Shanks, of the Winton Motor Carriage Company, are members of a syndicate of Cleveland capitalists who have purchased the twin screw steamship *Eastland*, the fastest craft on fresh water, and will put her in daily passenger service between Cleveland, Cedar Point and Toledo. The *Eastland* is 279 feet over all and has a passenger capacity of 3,400.

Owing to its rapidly increasing business, the Darracq Motor Car Company has found it necessary to utilize their entire building at 1989 Broadway, New York City, for showroom purposes and enlargement of office space, necessitating the removal of the repair shop to some other building. A new repair shop has been opened by them, using the entire two-story building at 20 West Sixtieth street for this purpose.

Many American automobile manufacturers are beginning to realize that there is a lucrative field in the export trade. The Maxwell has been successful in creating a foreign demand, and the export business which is in the hands of I. C. Kirkham, of Brooklyn, is rapidly assuming large proportions. In referring to a shipment of 68 Maxwells to the City of Mexico, Mr. Kirkham mentions that all the roads available for automobiling can be traversed in little more than an hour. The question is, "What do they do with the cars?"

Governor Stuart, of Pennsylvania, has attached his signature to the Roberts bill, which, while it attracted little attention, means much to the good roads interests throughout the State and received the quiet support of automobilists. This measure provides that when a township officer refuses or persistently neglects to perform his duties, twenty-five citizens of the township may petition the court for his removal, and if the judge decides that the charges of negligence are

proven, he may, after giving the delinquent a chance to be heard in his own defense, depose him and appoint a successor at once.

NEW AGENCIES ESTABLISHED.

The East Side Auto Station has secured the Pennsylvania gasoline car agency in Providence, R. I.

The Automobile Import Company, 90-96 Stanley street, Montreal, has taken the agency for the Reo for the province of Quebec.

Auto Sales & Livery Company, Providence, R. I., has been appointed Rhode Island agent for the Glide automobiles, with salesrooms at 7 Reservoir avenue.

A branch office has recently been opened by the New York and New Jersey Lubricant Company at 60 Wabash avenue, Chicago. H. C. Watts has been appointed manager.

A new salesroom and garage has been opened by the Jackson Motor Car Company, at 1413 McGee street, Kansas City, Mo., where the interests of Jackson automobiles will be looked after in the Southwest territory.

A. G. Powell, 1519 Spring street, Philadelphia, has acquired the local selling rights for the Chalfont, a 22-25-horsepower, \$1,300 car built at Lenover, Chester County, Pa. An agency for the Holman car, of Chicago, was also established last week by W. S. Williamson at the Crestmont Garage, at Fifteenth and Oxford streets, in the same city.

New agencies established by the Wayne Automobile Co., Detroit, Mich., are as follows: Solliday Motor Car Co., 321 Fourth street, Milwaukee, Wis.; Western Auto Company, Denver, Col.; John S. Watters, 233 Baronne street, New Orleans, La.; M. Francis Kane, 507 Mutual Life Building, Seattle, Wash. The Motor Car Agencies Company has taken over the business of J. W. Leavitt & Company, San Francisco, distributors for the Wayne in Northern California.

A company has been formed by Edw. A. Cassidy, late manager of the publicity department of the American Motor Car Manufacturers' Association, and Jas. G. B. Davy, who has been interested in different lines, both in this country and Europe, to do a general automobile accessory jobbing business throughout the Southern States. This new concern will be known as Cassidy-Davy & Co., and is located in Baltimore. They state that they will carry the largest and most complete stock of automobile accessories south of Philadelphia. Cassidy-Davy & Co. will be the southern sales agents for Ajax tires, Monogram oils and the Leavitt timer and distributor.

PERSONAL TRADE MENTION.

E. M. McIlvain, formerly president of the Bethlehem Steel Company, has been elected president and general manager of the Robins Conveying Belt Company, Park Row Building, New York.

T. F. Byrne, Chicago branch manager for the Franklin, severs his connection there on April 1. He has purchased an interest

in, and becomes manager of the Canadian Automobile Company of Montreal and Quebec, distributors of the Darracq in Canada.

L. A. Harris, for five years in charge of the Elephant Battery & Chemical Company, of London, England, and for the past year their American representative at New York, severed connection with that concern March 7 to engage as salesman with the R. E. Hardy Company.

David W. Henry, general traveling representative of the Electric Vehicle Company, has returned from an extensive cross country trip, the itinerary of which included practically every city of any importance between Hartford and Portland, Ore. Mr. Henry reports business along the west coast as particularly brisk. The San Francisco show, while small, afforded a good example of Western resourcefulness. After a few days in Hartford Mr. Henry will make a tour of Canada, taking in all the principal cities.

RECENT TRADE PUBLICATIONS.

Supplies are described and illustrated in the catalogue of the Brooklyn Motor Car Company of Bedford avenue, Brooklyn. The line includes everything needed by the automobile or the owner of the automobile.

The Bowers carburetor, constructed by the F. E. Bowers Company, New Haven, Conn., is a departure in several respects from the general type of carburetors and one that will give improved results. Its claims are presented in a brochure just issued by the manufacturers.

A descriptive booklet on the Perfection Spring has been issued by the Perfection Spring Company, 2414-2418 Superior avenue, N. W., Cleveland, O. The particular features of these springs and their advantages over other makes are interestingly put forth in the new publication.

A very pleasing hanging calendar has been issued by the Springfield Metal Body Company, of Springfield, Mass. The headpiece represents a smart touring automobile standing by the roadside with a smiling country scene as a background. The calendar is an artistic production.

Catalogue 7 issued by the Brennan Motor Manufacturing Company of Syracuse, N. Y., deals completely with the various types of motors constructed by this firm. Air and water cooled motors, double opposed and four-cylinder engines, gears, electrical parts, motor boats and their equipments are all described.

The Meteor is the title of an automobile built at the Meteor Automobile Works, Bettendorf, Ia. The machine is a 50-horsepower model, for which quite a number of good points are claimed, among them being a very effective transmission. The new catalogue tells all about it in engaging style.

"The Silent Partner" deals a little with the Globe Machine and Stamping Company's products and a lot about other things. The other things are just as interesting as the stampings and they are not lacking in variety or pithiness. The curious would do well to get "The Silent Partner"

for study. The address of the company is Hamilton avenue, Cleveland.

Automobile crank shafts as constructed by the Standard Connecting Rod Company of Beaver Falls, Penn., are described and illustrated in a small booklet issued by that company. Although only a limited portion of the firm's output can be dealt with in the limited space, there are examples of different crank shafts for all types from single cylinder to eight-cylinder engines.

Very complete details of the Stearns automobile are given in the handsome catalogue just issued by the F. B. Stearns Company, Cleveland, O. Mechanical drawings show every part of the mechanism, and the text further helps to give a thorough understanding of the machine. There is a good chapter on suggestions for adjusting and operating Stearns cars. The book should prove particularly useful to owners and operators of this automobile.

Darracq needs no introduction. The machines manufactured at the famous factory on the banks of the Seine at Paris are described and illustrated in the 1907 catalogue just issued by the Darracq Motor Car Company, 1089 Broadway, New York. Details are given of the new six-cylinder 50-horsepower Darracq which makes its bow to the public this year. Various other models of high-power four-cylinder machines as well as a number of elegant closed and runabout bodies are illustrated.

There is a sense of thoroughness and completeness about the automobile course set forth in the booklet issued by the New York School of Automobile Engineers, 146 West Fifty-sixth street. That there is room for a school of this nature is known to all, and the New York school seems to fill the bill. In their booklet full particulars are given

of the different day and evening courses for professional chauffeurs, or would-be professional chauffeurs, and for automobile owners. The home study course, too, is minutely described, and examples given of some of the lesson plates supplied to students. A number of illustrations of the school are included in the publication.

"Crucibles—Their Care and Use," is the title of a handsome little booklet by John A. Walker, general manager of the Joseph Dixon Crucible Company, Jersey City, N. J. The book is intended to instruct users of crucibles as to their proper care. It tells what graphite is and why crucibles are made of it. It tells why crucibles must be made of flake graphite. It tells why some crucibles are dark and others light and the importance of this fact. There is also much valuable allied information on the proportions of metal in commonly used alloys, on freezing, fusing and boiling points of various substances, the specific gravity of various metals and the comparative value of fuels. The double page center of the book carries a most vivid and realistic foundry scene.

MARTINI IMPORT CO. FORMED.

The Martini Import Company has been organized by Percy S. Palmer, formerly senior member of the firm of Palmer & Christie, Jos. E. Freeman and F. D. Palmer, to take over the agency for the Martini cars, which has been held by the firm of Palmer & Christie. With its enlarged capital and ample facilities the new company promise to make this car one of the most prominent foreign cars handled in this country. Mr. Palmer has left for Switzerland, to confer with the Martini Company in regard to receiving a larger allotment of these cars for the United States. The old home of the Martini car at 239 West Fiftieth street will be retained temporarily as a garage and machine

shop until arrangements are made for a larger and more convenient place in a more prominent location. A show room on Broadway will be engaged for temporary use. The officers of the new company are Jos. E. Freeman, president; F. D. Palmer, vice-president; Percy S. Palmer, secretary and treasurer.

STAMPED STEEL AUTO SPECIALTIES.

Added to the numerous stamped steel specialties designed particularly for automobile use, now being marketed by the Dover Stamping Company, 385 Putnam avenue, Cambridge, they are called

ing attention to a new design of oily rag and waste can for garage use, as called for by the requirements of the board of fire underwriters to meet the insurance regulations. Nothing is so liable to spontaneous ignition as a heap of oily waste, so that it is imperative to keep it in a fireproof receptacle. They are made in four sizes and are mounted on steel legs which hold them several inches above the floor. Among the other specialties manufactured by this concern are auto gasoline measures, oil cans, funnels and a full complement of other useful articles of a kindred nature for the use of automobilists.

BUSY SCENE IN THE ASSEMBLING ROOM OF THE FACTORY OF THE DRAGON AUTOMOBILE COMPANY, PHILADELPHIA.

THE AUTOMOBILE

PERCY PIERCE STARTING ON THE 1905 A.A.A. TOUR.

CHAIRMAN F. B. HOWER and his associates on the Executive Committee of the A. A. A. Touring Board have completed a task which has been complicated and difficult and well nigh impossible of accomplishment in such manner as to satisfy all interests involved in the conduct of the annual A. A. A. tour

for the Glidden and perhaps other trophies. Many conferences were held, involving owner and maker, and licensed and unlicensed, and the result should be the running of the largest and most successful semi-endurance tour ever held in this or any other country. All signs point to such an outcome.

July 10 will witness the start of the automobile cavalcade from Cleveland. Westward it will head for Chicago, but the exact route over which it will reach the bustling city on the shores of Lake Michigan is yet to be figured out. In its calculations the committee in charge is giving the most careful consideration to the question of night accommodations, and this may mean the elimination of several cities which would not exactly fit into a schedule calling for an average of about 125 miles a day. This requirement is none too easy over American roads.

In order to give the Westerners an opportunity of lavishing their bounteous hospitality upon the touring army, there will be a stop of a couple of days in Chicago. Then will follow the Eastward run, with its conclusion in New York City on or about July 23. Through peaceful Indiana, across fertile Ohio, a brief look at West Virginia, and then traversing the entire length of rugged Pennsylvania, perhaps dropping down into Washington and Baltimore, the caravan will have arrived in Philadelphia. Whether the Sunday stop will be in Atlantic City and the entry into New York up the Jersey shore is a problem to be taken care of by the sub-committee which shortly will make the preliminary survey. The total mileage will be about 1,400 miles, and will include all sorts and conditions of American roads, long stretches of level country and many miles of mountainous traveling. But the automobile of to-day should meet the test victoriously.

Much favorable comment has resulted from the plan evolved by the committee as to the disposal of the Charles J. Glidden trophy, which this time will go to the club whose entrants proportionately finish with the greatest total of points. Of course, a club to contest for the trophy must supply at least three entrants, but the owner of every car finishing the tour will receive a certificate giving its exact standing, those completing the entire

journey without penalization of any kind to have their certificates marked "Perfect." This will be a harder undertaking than ever before. Those surviving without losing points will earn the honor.

In its compilation of the rules the executive committee took the consensus of opinion as the basis of the conditions decided upon, the leading manufacturers expressing themselves as desiring to enter cars in a contest which would demonstrate the reliability and endurance qualities of their product. True it was that some argued for a pleasure tour pure and simple, and such it may be partially, but in strenuous degree. Nevertheless, provision is made for a division of non-contestants, which is to be a part of the tour and still relieved from the necessity of engaging in the struggle for the Glidden trophy. Those losing their right to contest for the trophy may, after having become disbarred through failure to comply with the rules, in the judgment of the committee, enter the non-contesting ranks for the remainder of the tour.

Replacement of parts not carried this year will be visited with penalties, and there will not be any such latitude as was permitted in the 1906 event. Each entrant will be required to furnish the manufacturer's list of regular standard equipment and price list of all extra parts carried. For any part replaced with parts not regularly furnished as standard equipment by the manufacturer there will be penalizations according to a schedule which would appear to have been carefully thought out. Before starting the entrant will be required to furnish an inventory of all extra parts carried in his car, and this information will be a matter of record. Only the driver and his mechanic will be permitted to participate in making any repairs or replacements. In the matter of tires a car may carry as many as its owner desires. A daily record of new parts placed on a car and any repairs or adjustments made will be required from the entrant. Failure to do so, fully and correctly, will be considered sufficient cause for disqualification.

It will be remembered that last year the fluctuating of watches caused trouble on several occasions. In the imposing of penalties

for reaching controls ahead of or behind schedules an allowance will be made of two minutes for variation in watches. Penalties

desires that particular attention be called to the fact so the committee will have opportunity of giving early attention to the hotel and other similar arrangements and thus insuring an improvement over the general accommodations which brought about so much dissension a year ago.

CHAIRMAN F. B. HOWER, HEAD OF THE A. A. A. TOURING BOARD.

will be effective for each minute or fraction thereof in excess of the aforesaid two minutes.

In the penalty schedule each club of three members starts out with a credit of 1,000 points, and for each additional car points are proportionately added. Penalizations are made on a sliding scale, both in time arrivals and replacement of parts.

An example of parts penalization is given in the rules as follows: "A club of three cars, one of which replaces a spring valued at \$10, will be penalized 3 1-3 points, which is 1-3 of a point for each dollar. A club of ten cars, one of which should do precisely the same thing, will be penalized one point, or 1-10 of a point for each dollar."

An example of time penalization is explained thusly: "A club of four cars, one of which is three minutes late arriving at a control, will be penalized 1-4 of a point for the one minute over and above the two-minute allowance. A club of eight cars, one of which is three minutes late arriving at a control, will be penalized 1-8 of a point for the one minute in excess of the two-minute allowance."

Chairman Hower is particularly urgent for early entrance, and

The executive committee which will have the burden of the tour includes, besides its chairman, L. E. Myers, Chicago; Philip S. Flinn, Pittsburg; James B. Dill, East Orange, N. J., and Dai H. Lewis, secretary. All are experienced and capable men, and have toured thousands of miles under all sorts of conditions of roads and weather.

Judging from the extraordinary amount of interest manifested in the tour, it is anticipated that the entry list may exceed 100, and the entire caravan may embrace some 600 or more people.

During the preparation of the rules for the tour a strong effort was made to have the contest for the Glidden trophy open both to touring cars and touring runabouts; in fact, the N. A. A. M. committee was very much in favor of including the runabouts. Chairman Hower agreed to leave the matter to a decision of the A. A. A. Board of Directors. The subject was discussed at the March 27 session, and, while it was freely admitted that runabouts had made vast strides in popularity during the past year and a large sale was presaged for this season, it was argued and voted that the admission of runabouts might discourage the entering of the big touring cars.

It is likely that the Executive Committee will discuss at its next session the advisability of placing a trophy in competition for the runabout class, especially if early entrants make known their desire to contest for a runabout cup rather than participate with a heavier and more commodious car for the Glidden trophy. It has been stated from various sources that a large number of runabouts will be available if provision is made for this class of car. A score of such entrants seem to be assured.

Percy Pierce, of the Automobile Club of Buffalo, was the winner of the 1905 tour, the first contest for the trophy. A provision in the deed of gift left the trophy in the possession of the winner until it was won by another. The 1906 event resulted in a tied score by thirteen cars, one of which was driven by Percy Pierce, and therefore he retained the trophy. The revised conditions make it impossible for the Bison to make himself a three-time holder, but he can assist his club in keeping the trophy in Buffalo.

RULES GOVERNING THE 1907 A. A. A. TOUR

CONCERNING ENTRANTS.

1. It will be assumed that every entrant is acquainted with these rules, and by entering for the tour agrees to abide thereby, agrees to accept the official records, and authorizes the American Auto-

mobile Association shall not be responsible for any damage that may be done to any car, its passengers or contents during the tour, nor for the theft of any car or any of its accessories or contents, the same being at all times subsequent to such entry, and until the close of the tour, at the risk in all respects of persons entering same.

QUALIFICATIONS.

1. Each entrant shall be a member of the American Automobile Association, but if competing for the Glidden Trophy must be a member of a club affiliated with the American Automobile Association, and each club to compete for the trophy must have at least three entries.

2. Teams from clubs joining the Association after April 1 and competing for the Glidden or other trophies must be made up of cars of more than one manufacture.

mobile Association to publish them in such manner as it shall determine.

2. Each entrant shall hold the American Automobile Association harmless and indemnify it against all loss or damage resulting directly or indirectly from or growing out of the operation, management or control of the car entered by him.

3. It is one of the conditions upon which entries of cars are accepted by the American Automobile Association, that said Ameri-

ENTRIES.

1. The time for receiving entries will expire on July 3, 1907, at 12 o'clock noon, at the office of Frank B. Hower, Chairman Touring Board, 760 Main street, Buffalo, N. Y. Each entry for the 1907 event must be accompanied by the entrance fee—\$100. Numbers for the tour will be issued in the order in which the entries are received.
2. Each entrant shall give all details asked for in the entry blank and such additional information as the committee may from time to time require.
3. The American Automobile Association reserves the right to refuse any entry.

TOURING CONDITIONS.

1. Each car entered shall be driven by the entrant, or a driver or drivers nominated by him and approved by the committee; when the car is driven by other than the entrant, the latter shall ride in the car, unless excused by the committee.
2. Cars must at all times during the tour carry mufflers and mudguards, and be equipped as per manufacturer's catalogue specifications: shall carry not less than four passengers of an average weight of 125 pounds or other equivalent in ballast, and shall have touring car bodies with tonneau.
3. No replacements, replenishments, adjustments, repairs or inspection shall be made upon any car after the same shall have been registered at any night stop of the tour, and before it shall have registered out the next succeeding morning. No replacements (except tires) shall be made with parts not inventoried and carried at the start, and if replacements, except as above specified, are made, the entrant may continue the tour, but not as a contestant. Each entrant may carry as many tires as desired.
4. Each car shall have its official number prominently displayed on each side, or in front and rear.
5. No record of any previous performance, or sign, or other indication of the maker's name, other than the nameplate, usually attached to the vehicle as sold to private owners, shall be displayed on any car at any time during the tour.
6. The trophy will be awarded to a club, but the score of each individual car will be recorded during the tour, and at the finish of the contest each entrant, unless previously disqualified, will receive a certificate in accordance therewith.
7. Each entrant must furnish the manufacturer's list of the regular standard equipment and the manufacturer's price list of all extra parts carried, and for any parts replaced with parts not regularly furnished as standard equipment by the manufacturer, contestants will be penalized as per penalty schedule hereinbelow set out.
8. Each entrant must furnish an inventory, previous to the start, of all extra parts carried in his car, and the same shall be put in the records.
9. A car may carry but one mechanic, and all repairs must be made by him, the operator, or both, and no one else shall participate in any way in making any repairs or replacements.
10. A statement must be made by the operator and attested by each occupant of the car at the conclusion of each day's run, as to what new parts were put on the car and what repairs or adjustments, if any, were made, and failure to do so, fully and correctly, shall disqualify.

SCHEDULES.

1. The committee will publish a schedule for each day, establishing such checking points as it may deem proper. This schedule will fix the exact time when each car must reach each control, and when it shall finish each day's run, but will not require any entrant to operate his car at a higher rate of speed than is permitted by law. Each car failing to reach controls, or to finish the day's run at the time fixed by the schedule, will be penalized according to the penalty schedule herein given. The committee shall have power to disqualify any car for traveling at any speed which the committee may consider excessive under the conditions existing at the time, and without reference to these rules.
2. On arrival at night controls, each car must take its place in line and register in regular order. Cars failing to do so, will be disqualified. Contestants for the Glidden Trophy shall, however, be entitled to precedence in registration over non-contestants.
3. Immediately following the registration at each night control, each car shall be delivered into the custody of the officials of the tour, to be by them held at owner's risk, and kept under direct charge and supervision of such officials or their agents until the hour for starting on the following morning, and no car shall be available for tuning up, adjustments, filling with gasoline or water, or for any other purpose, until after it shall have registered as starting on the next day's run. The committee shall have power, etc., at all times to make such examinations of the cars and their contents as may be deemed advisable.

PROTESTS. DISQUALIFICATION.

1. Any participant in the tour desiring to file a protest must first deposit the sum of \$10 with a member of the committee, which sum will be retained by the American Automobile Association if the protest is not sustained, and if the protest is sustained the protest fee will be returned to the person making such deposit. All protests must be made in writing, and will be considered by the committee at the earliest practicable moment, and a decision rendered as soon as practicable thereafter.
 - (a) All protests as to entries must be made before the start.
 - (b) All protests as to unfair ruling, route, etc., must be made within twenty four hours after the occurrence.
 - (c) All other protests shall be made during or immediately after the tour is concluded, and before the award is made.
2. No entrant or car will be disqualified until the person in charge shall first have been notified of the act complained of, and if the act be denied, the committee will give the owner or person in charge of such car a hearing, after which a decision will be rendered. Upon notice that such car has been disqualified, it shall cease to run in the contest, the official numbers shall be removed, and such entry shall not receive any certificate, but shall be mentioned in the records as having been disqualified, and no entrant of any car that may be disqualified shall have any claim of any kind or nature whatsoever against the American Automobile Association, or any member or members of the committee or any official of the tour, because of such disqualification or the publication thereof or failure to mention the performance of the disqualified car prior to its disqualification.

failure to mention the performance of the disqualified car prior to its disqualification.

SPECIAL TRIALS OR TESTS.

1. In the event of a tie at the end of the tour, the committee may require such other and further trials or tests as it may deem necessary or advisable to establish the awarding of the trophy.

PENALTY SCHEDULE.

The Glidden Trophy will be awarded to the club having the greatest number of points at the end of the contest. The method of scoring will be as follows:

Club of	Initial credit	Penalizations per minute or fraction thereof in excess of two minutes at controls.	Penalizations per dollar or fraction thereof of value of parts as per manufacturer's price list.
2 cars	1,000	1-3 point	1-3 point
4 "	1,010	1-4 "	1-4 "
5 "	1,030	1-5 "	1-5 "
6 "	1,060	1-6 "	1-6 "
7 "	1,100	1-7 "	1-7 "
8 "	1,150	1-8 "	1-8 "
9 "	1,210	1-9 "	1-9 "
10 "	1,280	1-10 "	1-10 "

ROAD REGULATIONS.

1. Entrants must conform to all laws and ordinances and rules of the road, and any entrant violating any of the provisions of these rules, or of other rules adopted by the committee, or who shall fail to show due consideration to other participants in the tour, or other users of the highways, may be disqualified by the committee.
2. Any car whose owner or driver shall be arrested for a violation of speed laws, or of any law or ordinance, may, in the discretion of the committee, be disqualified.

CONTROLS.

1. All contestants must have their cars ready at 7 o'clock each morning. Checkers will be at their stations at that time prepared to start the cars.
2. Each entrant must, upon starting on each day's run, sign a statement submitted by an official of the tour fixing the time of his departure. Failure to comply will result in disqualification. Each day's tour shall be preceded by a pacemaker, designated by the committee, and any entrant who passes the pacemaker shall be disqualified. If the pacemaker breaks down or is compelled to travel at a rate of speed so slow as in the opinion of the committee to unduly impede the progress of the tour, his flag shall be transferred to the first car overtaking him, which car shall thereafter become pacemaker, subject to the same conditions.

Penalties will be imposed for reaching controls ahead of, or behind schedules. Two minutes will be allowed for variation in time pieces. Penalties will be effective for each minute or fraction thereof in excess of aforesaid two minutes.

EXAMPLE. PARTS PENALIZATION.

A club of three cars, one of which replaces a spring valued at \$10, will be penalized 3-3 points, which is 1-3 of a point for each dollar. A club of ten cars, one of which should do precisely the same thing, will be penalized one point, or 1-10 of a point for each dollar.

EXAMPLE. TIME PENALIZATION.

A club of four cars, one of which is three minutes late arriving at a control will be penalized 1-4 of a point for the one minute over and above the two-minute allowance. A club of eight cars, one of which is three minutes late arriving at a control, will be penalized 1-8 of a point for the one minute in excess of the two-minute allowance.

NON-CONTESTANTS OF THE TOUR.

1. In order to provide for those who desire to participate in the

annual A. A. A. Tour, and do not care to contest for the Glidden or other trophies, a separate class of "Non-Contestants" is created, and those coming under this head will not be subject to Articles 2, 3, 6, 7, 8, 9, 10 of "Touring Conditions"; Articles 1 and 2 of "Controls"; Articles 1, 2, 3 of "Schedules"; and Article 1 of "Special Trials or Tests."

HOW DISQUALIFIED CARS MAY CONTINUE.

1. Contestants for the Glidden Trophy failing to comply with the rules governing same, and thereby losing their status as contestants, may, in the discretion of the committee, continue on the tour as "Non-Contestants."

POWERS OF COMMITTEE.

1. In the event of a dispute concerning the interpretation of the rules, the decision of the Executive Committee of the Touring Board of the American Automobile Association shall be final.

2. The Executive Committee of the Touring Board reserves the right to alter or amend, suspend, or repeal these rules from time to time, up to and including the end of the tour and final award, as may in its judgment be deemed expedient.

PROGRESSIVE A. A. A. ACTIVITY BRINGING RESULTS

THAT the Hotchkiss administration of A. A. A. affairs is certain of doing much was apparent at the spring meeting of the Board of Directors, held in New York City, March 27, at the clubhouse of the Automobile Club of America. Two State associations were added to the membership list, Connecticut and Minnesota becoming part of the national organization. Applications from Rhode Island, Maryland, Indiana, Michigan, Wisconsin, Kentucky, Missouri and Iowa are expected soon.

Recognizing that racing results in some benefits of a substantial nature to the industry, the directors sanctioned a suggestion from a coterie of well known makers that a contest for American touring cars be conducted soon after the annual Vanderbilt Cup race in October next. The event would be limited to regular stock touring cars, except that the chasses would be mounted with racing instead of touring bodies. The subject was referred to the Racing Board with power to arrange such a contest.

It was decided to designate the second Wednesday of June in each year as a National Orphan's Day, A. A. A. clubs being asked to hold their affairs of this character this year on Wednesday, June 12, if local conditions permit.

President Hotchkiss recommended the formation of two new boards one to be known as the Technical Board and the other the Publication Board. The duties of the Technical Board, made up of automobilists without trade affiliations, would be to conduct such tests as might be suggested to determine the worth of automobiles in general and their different parts and appliances. The work of the Publication Board would be the preparation of a year book, digests of State laws, maps and route cards, and possibly a monthly bulletin. The establishment of two such boards was referred to the Executive Committee.

Exhaustive reports were presented by Chairman Terry of the Legislative Board, who had prepared the draft of a model State law; Chairman Hooper of the Good Roads Board, who recommended that State committees of his board be formed in States where there were no State bodies; and Chairman Hower of the Touring Board, who gave the conditions for the annual tour.

The roll call showed the following directors present:

President, William H. Hotchkiss, Automobile Club of Buffalo.
 First Vice-president, Lewis R. Speare, Bay State Automobile Assn.
 Charles Thaddeus Terry, chairman Legislative Board.
 Frank B. Hower, chairman Touring Board.
 Robert P. Hooper, chairman Good Roads Board.
 Secretary, Frederick H. Elliott, Automobile Club of Syracuse.
 Osborne I. Yellott, Automobile Club of Maryland.
 Sidney S. Gorham, Chicago Automobile Club.
 J. H. Morse, Automobile Club of Hartford.
 Walter E. Edge, Atlantic City Automobile Club.
 John P. Coghlin, Worcester Automobile Club.
 A. R. Pardington, Brooklyn, N. Y.
 A. G. Batchelder, New York Motor Club.

George A. Post, North Jersey Automobile Club.
 J. H. Edwards, Automobile Club of Hudson County (N. J.).
 W. H. Chase, Wauchussetts Automobile Club (Mass.).
 Walter C. White, Cleveland Automobile Club.
 George H. Smith, Quaker City Motor Club (Penn.).

Earlier in the day and preceding the meeting of the Board of Directors, there were sessions of the Legislative and Good Roads Boards, considerable work being outlined for the near future. There was no meeting of the Racing Board, owing to the indisposition of Chairman Jefferson De Mont Thompson.

HOTCHKISS ADDRESSES OHIO STATE BODY.

CLEVELAND, April 1.—At the annual meeting of the Ohio State Automobile Association, held Saturday at the clubrooms of the Cleveland Automobile Club, five clubs were represented: Cleveland, Cincinnati, Springfield, Lima, and Elyria. President F. T. Sholes presided and presented a very satisfactory report.

President W. H. Hotchkiss, of the A. A. A., made an enthusiastic address wherein he dwelt upon the necessity for a national organization, particularly calling attention to the need of a Federal law which will permit an automobilist to go anywhere in the country after having complied with the registration law of his own State.

In the evening the Cleveland club gave a smoker to its members and guests, it being the largest gathering of automobilists ever gotten together in Cleveland. President Hotchkiss delivered another address in which he emphatically condemned careless drivers. He referred to the liberality of the speed laws in Vermont, where the autoist's judgment is taken into consideration, and stated that efforts would be made to enact similar laws in every State and to induce Congress to act upon the matter.

ABOUT THE STATEN ISLANDERS OF NEW YORK

ST. GEORGE, S. I., April 1.—At its meeting to-night the Richmond County Automobile Club decided to hold another dinner and run on April 28, and the new Terra-Marine Inn at Huguenot was selected as the destination. The entertainment committee, consisting of Emil H. Poehn, chairman; W. O. Sprigg, G. H. Waters, Charles A. Schultz, and J. J. Worrell, was requested to proceed with the necessary arrangements. At this meeting George H. Waters was elected a director to the New York State Automobile Association. A resolution was passed favoring federal and uniform automobile legislation which shall grant a national license to tourists and remedy some of the existing evils resulting from State legislation. A. B. Pouch and John Bittner were elected to membership.

AIR TOURISTS CONTINUE THEIR SPRING FLIGHTS

PARIS, March 27.—The return of Spring has brought the cloud brigade out of doors. Delagrange, Blériot, Vuia, and Santos-Dumont have all made experiments with their respective machines in the neighborhood of Paris. M. Blériot, of automobile lamp fame, has been busy all the winter on a new type of aeroplane, differing entirely from the one he used on the Lac d'Enghien last summer. It has a central frame on which is carried a 24-horsepower Antoinette motor driving a two-blade propeller in the rear and two wings modeled like those of a bird. The light framework is covered with parchment and is designed to offer very little resistance to the wind. The machine abounds in novel features thus, the two wings can be raised or lowered at will to facilitate turning, the two rudders placed in front may be operated either together or separately, and the two blades of the propeller can be driven either as one or independently at different speeds. The machine is mounted on a couple of bicycle wheels with efficient steel springs and a pneumatic cushion to prevent breakage when striking the ground.

Santos-Dumont escaped without injury. He declares that he is not sorry the machine is smashed, for he was disappointed with the quality of the wood, which was much too brittle. Fresh material has been ordered and a new machine will be commenced to be fitted with the 100-horsepower, sixteen-cylinder motor now being built at the Antoinette factory.

French Gordon-Bennett Balloon Pilots Chosen.

Alfred Leblanc and René Gasnier have been appointed by the Aero Club of France as the national representatives in the Gordon-Bennett balloon race at St. Louis, next October. The third pilot will probably be selected towards the end of May. A delegate will be sent from the Aero Club of France to assist in the organization of the balloon race at St. Louis and the club has promised a gold medal to the pilot who succeeds in capturing the Bennett Cup for France. Alfred Leblanc is thirty-eight years of age, is a skilled hunter, skater and automobilist. He has made more than fifty balloon ascents in his balloons, the

THE NEW BLÉRIOT AÉROPLANE LEARNING TO USE ITS WINGS ON THE BAGATELLE POLO GROUND, PARIS.

Unfortunately the initial trip was not a complete success. While traveling at a rapid rate the wheel supports broke and the apparatus collapsed. No serious damage was done.

M. Vuia, who has the honor of being the second man in France to fly on a heavier-than-air machine, has decided after several trial trips this week to abandon the carbonic acid motor in favor of an Antoinette of 24-horsepower.

After two or three unfortunate attempts to fly, M. Delagrange has met with success. The aeroplane built for him by the Voisin Frères has just covered a distance of about sixty yards in excellent style. Though still showing signs of too light construction, the aeroplane has proved that it is built on right lines. Santos-Dumont, who was present when the flight took place, heartily congratulated his rivals.

Santos-Dumont's Aeroplane Is Wrecked.

According to a *Herald* cable from Paris, Santos-Dumont completely smashed his machine in an attempted flight on the Saint-Cyr drill ground. For several days trials had been made to familiarize the pilot with the *Bird of Prey*, and finally an attempt was made to travel at the forty miles an hour necessary to raise the aeroplane from the ground. After covering half the length of the ground the machine swerved, bounced into a hole and was smashed in two. One of the wings was hopelessly destroyed.

Albatross and the *Cythère*, and gained second prize in the Grand Prix of the Aero Club of France in 1906. He is also holder of the Gaulois long-distance trophy for a voyage from Paris to the Baltic. René Gasnier is an enthusiastic yachtsman, thirty-three years of age, who has sailed extensively in Eastern waters. He made his first balloon ascent in 1904 and is now the owner of three balloons.

WALTER WELLMAN'S VISIT TO THIS COUNTRY.

PARIS, March 27.—The members of the Wellman north pole expedition are completing the preparation of the balloon *America*, and will leave here shortly for Tromsø, Norway, whence they will depart for Spitzbergen June 1. The balloon, or airship, has been entirely reconstructed, has new motors, and possesses a lifting power of 19,500 pounds.

Walter Wellman, leader of the expedition, will in the meantime pay a visit to the United States. He is on board the *Kaiser Wilhelm II.*, which is due in New York on April 3. Replying to criticism to the effect that his airship had not been tried, Mr. Wellman declared that the *America* was built for arctic conditions and would undergo thorough trials at Spitzbergen. In the event of these being satisfactory the expedition would start for the pole at the end of July or the beginning of August.

JAMESTOWN AERONAUTICAL CONGRESS:

The Jamestown Exposition is having erected a special building to house the aeronautical exhibits. There will be balloon sheds and a hydrogen generating plant located conveniently in the aeronautic concourse. Coal and hydrogen gas will be supplied without cost to all contestants. A large number of applicants have already signified their intention of exhibiting aeronautic material of both heavier and lighter-than-air types. There will be cups and trophies for balloon and airship races and all sorts of competition. To Ernest La Rue Jones, No. 12 East Forty-second street, New York City, all inquiries should be addressed.

The following is the schedule of competitions between April 26 and November 30:

- No. 1.—Special race limited to members representing recognized aero clubs for club championship, May 4.
- No. 2.—Dirigible balloon competition, June 1.
- No. 3.—Competition of balloons for distance, June 15.
- No. 4.—Competition of balloons for duration, Aug. 3.
- No. 5.—Competition of balloons for objective point, Sept. 7.
- No. 6.—Competition of balloons for altitude, Nov. 16.
- No. 7.—Competition of balloons in pursuit of pilot balloon, Aug. 17.
- No. 8.—Competition of carrier pigeons, flight from Aeronautical Concourse, Exposition Grounds, May 18.
- No. 9.—Simultaneous release of large number of small balloons carrying messages, May 18.
- No. 10.—Flying devices heavier than air, with motor and operator, Sept. 14.
- No. 11.—Flying machine models with motor, Aug. 24.
- No. 12.—Flying machine models without motor, and carrying operator, Sept. 14.
- No. 13.—Kites for altitudes, Nov. 2.
- No. 14.—Kites for steepest angle of flight, No. 9.
- No. 15.—Kites carrying operators, Nov. 16.
- No. 16.—Registering balloons, July 13.
- No. 17.—Competition of balloons and automobiles. (Date to be coincident with the arrival of the Automobile Tour.)
- No. 18.—Competition of dirigible balloons and automobiles, May 25.
- No. 19.—Competitions of photographs taken from balloons or kites.
- No. 20.—Competition of photographs taken of balloons, aeroplanes or other aeronautical objects.
- No. 21.—Competition of photographs of meteorological phenomena. (Exhibits for No. 19, 20 and 21 to be ready April 26, and continuing on exhibition throughout the Exposition.)
- No. 22.—Signalling competitions with balloons or kites, Oct. 12.
- No. 23.—Hot air balloon competition, Oct. 5.
- No. 24.—Dropping (harmless) shells nearest selected objective point or target.
- No. 25.—Competition for longest trip, open during Exposition.

SWITZERLAND'S BALLOON RACE ENTRANT.

A communication has been received by the Aero Club of America from E. Messner, of Kewanee, Ill., applying to enter the Gordon Bennett International Aeronautic Cup Race. He is a pilot of the Aero Club Suisse and is writing to his club for permission to represent them in this race. The Swiss Club will, in turn, apply to the Federation for permission to enter. The entries having officially closed February 1, it would appear certain that the entry will not be accepted.

ELECTION OF THE FLORIDA EAST COAST A. A.

DAYTONA, FLA., April 1.—The annual meeting of the Florida East Coast Automobile Association, held recently, resulted in the selection of the following officers for the ensuing year: President, Major Foster; first vice-president, George Sebring; second vice-president, S. H. Gove; treasurer, Fred Conrad; secretary, T. Edward Fitzgerald; directors, Asa Paine, J. H. Allen, George H. Clark, J. B. Parkinson, E. L. Potter, N. A. Lewis.

Following the election a banquet supper was tendered by C. G. Burgoyne, the first president of the association, and he pleasingly presided as the toastmaster of the occasion. The speechmakers included: W. J. Morgan, President-elect Foster, ex-President Paine, ex-Gov. Harding, of Ohio; Hon. J. B. Parkinson, Com. J. H. Allen, John Anderson, Mayor Green, Dr. Bennett, and several others.

AUTOS DRIVE PARIS NEWS PLANTS.

PARIS, March 20.—A prolonged wail of despair wafted heavenward—or elsewhere—when at 5 o'clock on Friday evening the electric lights of Paris went out as a result of the strike of the electricians. Householders shrugged their shoulders and thanked their stars that Paris apartments are still provided with gas or kerosene lamps. Theater managers closed their establishments and were philosophical. Newspaper men cursed loud and deep.

The first panic over, there was a rush for automobiles. Many an excited manager jumped into one of the numerous automobile cabs skimming along the boulevards and cried in feverish tones, "Panhard, Darracq, De Dion factory, and let her out as if the diable were on your heels." But the automobile factories which encircle Paris were closed for the night and gasoline-electric groups were at a premium. Commandant Krebs was closing his desk at the Panhard factory when a husky voice over the telephone asked if he could not send a portable plant to help the auto journal *Les Sports* out of its difficulty. Two gasoline-electric groups, each of 100 horsepower, were supplied, electric arc lamps similar to those used on the cycle tracks were obtained and one newspaper at least was saved from ruin. *L'Auto* had an Aster electric group in reserve which proved quite capable of running the line-

DE DION AUTO PRODUCING PARIS NEWSPAPER.

types. In the newspaper quarter steam locomobiles puffed away all night side by side with gasoline delivery trucks and a smaller number of touring cars, all doing their best to furnish the electricity which the workmen denied. In one print-shop a 12-horsepower Darracq was raised off the floor, a rear wheel replaced by a driving pulley and belted onto the shaft of a linotype installation. Léon Bailby, who presides over the editorial destinies of the *Intransigeant*, brought along his De Dion automobile, ordered a dynamo, fixed the two in the street, belted them up and produced enough current to give the latest news to the public. The director of *Paris-Sport* owns a new 24-horsepower Hotchkiss which he used to drive a dynamo, smashing the body work to get the connection between the engine and dynamo with the recklessness of despair. Henry Fournier, who is now passing his time profitably selling automobiles to American and other millionaires in Paris, dismounted a magnificent 130-horsepower Itala motor intended for the Monaco motor boat meet, and gave it up to drive a dynamo.

In the Rue Royale, and on the main boulevards, the fashionable cafés were lighted with automobile searchlights, lanterns and candles. The costly headgear of a pretty Parisienne catches fire; the crowd laughs. Fournier passes too near the open exhaust of one of his big Itala engines and his silk hat is left behind for the ragpicker. Bravo, cry the ladies. The strike is fine fun for the boulevardiers, but newspaper proprietors are giving orders for gasoline-electric groups to be kept in reserve.

WHAT AUTO INVENTORS ARE DOING ABROAD

It seems so long since the type of car that banged its way along with an unduly audible announcement of its coming was prevalent that the average autoist has forgotten the time when mufflers were such in name only, and the volume of sound did not vary greatly whether the alleged silencer was open or shut. In the same period, the motorcycle has not been improved

place shown in the sectional drawing, and a small by-pass allows the pressure to become equal on either side of the cylinder so that no action takes place.

Hydraulics Applied to Change-Speed Gear.

Although the application of hydraulics to the car is nothing entirely novel, as considerable attention has been paid to the matter of perfecting a hydraulic type of clutch, the latter power has not so far as known ever been utilized in the same manner as it is employed in the White patent speed gear, shown at the recent commercial vehicle exhibition in Olympia and described in *Motor* (London). It is designed along planetary lines and consists of a sunwheel carried on the tailshaft and planetary pinions supported by bearings in two plates bolted together on either side of the sunwheel, and fixed to the engine shaft. Outside one of these disks (on the engine side) there are small cranks attached firmly to the spindles of the planetary pinions, and used to drive the plungers of small oil pumps arranged symmetrically round the disk. Oil is sucked in through ball valves in the head of the barrels, and expelled through ports, the size of which can be controlled by an outside lever. According to the freedom allowed for the oil circulation, the speed of the tailshaft is regulated. When the engine is running, and the car not in motion, the oil pumps are permitted to work freely, and the planetary pinions revolve round the sunwheel without turning it. Directly the oil-outlet ports are partially closed the sunwheel commences to revolve at a slow speed, and the tailshaft obtains power to drive the car. The speed of rotation of the sunwheel increases as the pumps work more and more slowly, until, when these stop altogether, there is a solid drive right through. For the reverse a separate train of wheels is provided. There are certain disadvantages in the system. At slow speeds the power lost in friction forms a large proportion of the power developed, but as it is possible to run very largely on the direct drive the total loss will never amount to much, while it has the great advantage that the higher the speed the more efficient it becomes. A gear of this nature, flexible in the extreme, is a thing to be desired.

A New Self-Contained Distance Recorder.

Quite a departure in the shape of distance recording instruments is to be found in an English device which has been given

perceptibly in this respect, and this constitutes one of the greatest drawbacks of the light power-driven two-wheeler from the public point of view. The layman cannot understand why the diminutive machine makes a fuss so disproportionate to its size and so much greater than that of its larger competitors. The Auto Cycle Club of Great Britain recently instituted a contest for improved devices of this kind, the awards in which have recently been made public. The chief considerations were back pressure, noise, facility of attachment, weight and strength, capacity, means of cleaning and maintenance, and cost. As will be noted from the illustrations, taken from *The Motorcycle*, the devices which gained the first three awards are distinguished by their simplicity. The first, shown by Fig. 1, is known as Sharpe's Universal Silencer; the second, Fig. 2, is the Universal Victoria Silencer, and the third, Fig. 3, is the Universal Paragon Silencer. The Sharpe is made of a seamless brass shell with two smooth aluminum bulbs; the Victoria consists of but two aluminum bulbs cast with flanges, while the Paragon consists of two annular concentric chambers and a series of perforated disks.

Another Entrant in the Shock Absorber Field.

Of the many anti-shock devices now on the market, those depending on the elastic force of compressed air hold certain advantages, says *The Car*. A useful apparatus of this type is the Amans, which is composed of a steel cylinder fitted inside with a piston worked by means of a chain passed over a small cog-wheel and joined to the axle of the car. The piston is formed of a cup-leather which, when pulled upon, presses hard against the cylinder walls and allows no air to escape past it. A small ball valve placed at one end of the cylinder enables air to be drawn in freely, and a suitable cap prevents wet and dust from penetrating. The body of the cylinder is fixed on to the frame of the car, and the working of the machine is as follows: When the car passes over an obstacle the springs give and the chain fixed to the axle becomes slack and allows the spiral spring in the cylinder to push the piston up to one end. The vacant space in the cylinder is thereby filled with air, and when the frame tries to return quickly into its place, this is compressed and offers a strong resistance which decreases gradually. When the chassis is in its normal position, the piston occupies the

FIG. 1.—The new Amans shock absorber; tube cut a way, showing interior.
FIG. 2.—Sectional view, showing position and method of application.

the title of "Perfection" by its makers and is described in a recent issue of the *Autocar*. The recorder screws upon the hub of the front wheel in place of the ordinary axle cap and is applicable to any make of car. Without going into details of its mechanism, it will suffice to point out that its principle of work-

ing is based upon the fact that the axle of the wheel is fixed while the hub revolves. The mechanism consists of a pair of driving springs which engage with the nut at the end of the front axle. These springs are attached to a worm which drives the interior mechanism; consequently the instrument is entirely self-contained and positively driven. It is made in two patterns—trip and non-trip. Both give a continuous record up to 9,999 miles, but on the trip type there are two more dials which record up to 99 miles and automatically return to zero and recommence. This trip portion of the mechanism can be set back to zero at any time by a little button in the side of the instrument. Careful tests of the instrument extending over a considerable period and during the worst weather have shown it to be entirely accurate and dependable. Fractions of a mile are also recorded by the dial hand, which revolves once for every mile.

Device to Aid Use of Motor as a Brake.

As the result of the long-continued discussion that has been carried on pro and con regarding the advantages and the reverse of using the motor as a brake, during the course of which much of interest has been brought out, though more of absurdity has

THE SAURER MOTOR BRAKING DEVICE AS APPLIED AND OPERATED.

resulted, a Continental inventor has brought forth a device to enable the motor to be utilized as a brake, which is described in *La Suisse Sportive*. It permits of varying the passive resistance of the motor to an extent equivalent to that of its rated power, and consists of a method of regulating the compression of the air that is taken in. This is done by taking pure air through the carbureter and by delaying the opening of the exhaust valve. Under ordinary conditions no braking effect is gained from the compression alone, as it is offset by the subsequent expansion; but if the exhaust be advanced, say 90 degrees on the crank circle, part of the compression is utilized in retarding the revolution of the shaft, the rest escaping. The sooner the exhaust valve opens, the sooner it closes, that is to say, before the upper dead center, and in consequence a certain amount of air is compressed and then released before its expansion imparts any power to the motor, so that the work represented by its compression is entirely absorbed.

To obtain the maximum braking power, the exhaust may be opened during the course of an explosion and the four parts of the cycle then become as follows: (1) Inspiration through the open air valve; (2) compression, all valves closed; (3) opening of exhaust valve at upper dead center and escape of compressed air; new inspiration of fresh air at atmospheric pressure through exhaust pipe; (4) compression, all valves closed; (1a) opening of admission valve at upper dead center and escape of compressed air, new inspiration of air at atmospheric pressure; (2a) com-

pression, all valves closed, and so on. In consequence, each piston on its upward stroke furnishes an amount of resistance equivalent to the power required to compress the air in the combustion chamber, and none of this effort is returned to it by expansion on the down stroke. The amount of braking effort thus produced may be regulated at will; this is done by the driver by means of a small lever mounted on the steering wheel, as shown by the accompanying illustration of the device as applied to a motor.

PRICE OF GASOLINE STIRS EUROPE.

Europe has real fears that the price of gasoline will increase to such an extent that it will be a costly matter to satisfy the moderate appetite of a modern motor. The situation is not yet alarming, but there has been a steady increase in the price of gasoline during the last eighteen months, which, if continued, might lead to a serious situation. From 28 centimes a liter in the middle of 1906, the average price in France increased to 30 centimes at the end of the year and now stands at 34 centimes, the highest price since the beginning of the automobile industry in 1900. The profit of the retailer has decreased in greater proportion than the increase in price, a retailer who formerly made a profit of two to three dollars on a 22-gallon sale now gets but 50 or 60 cents.

The reason of the increase is readily found. Automobiling has increased in proportions that were undreamed of a few years ago; the consumption of gasoline has augmented at a ratio altogether out of proportion to the increase in the consumption of auxiliary products such as kerosene and lubricating oils, so that gasoline, which was once a minor product, owing to the small demand, is now the principal object of refining.

In France there are four large refineries at Rouen, three at Bordeaux, two at Cete and one each at Havre, Douai, Cateau, Roubaix, Lille, Bonnières, Colombes, Aubervilliers and Marseilles. These together produce roughly 1,760,000 gallons of gasoline per annum. The rest has to come from abroad.

The United States is not only the largest producer of petroleum, but the greatest exporters of gasoline. The following table shows the world's production of petroleum from 1903 to 1905, the figures being barrels of 35 gallons each:

	1903	1904	1905
United States	100,400,000	118,000,000	114,700,000
Russia	75,500,000	78,500,000	54,900,000
Straits Settlements	6,600,000	6,300,000	7,700,000
Gallcia (Austria)	5,200,000	5,900,000	5,700,000
Roumania	2,700,000	3,600,000	4,400,000
India	2,500,000	3,300,000	4,100,000
Other Countries	2,240,000	2,820,000	2,730,000

According to *La Vie Automobile*, the United States cannot continue to supply foreign countries with gasoline as she is doing at present. Automobiling is developing at such a rapid rate that in a few years Americans will consume their entire output of gasoline. This is certain from the fact that the American petroleum springs are not rich in hydrocarbon. Russia, another large producer, is in the same position as the United States; with the exception of one district of little importance, Russian petroleum produces only a small percentage of gasoline.

Roumania plays an important part in the production of gasoline, certain of its petroleums producing as high as 60 per cent. of gasoline by distillation. The exportation of gasoline from Roumania has increased in a notable degree: 29,563,572 hecoliters in 1903, 50,351,778 hecoliters in 1904 and 62,696,098 hecoliters in 1905. Of the 1905 production, 37,276,578 hecoliters, more than half the total production, was sent to France.

With the exception of Roumania, which, despite its rich wells cannot claim to supply the world, the demand for gasoline increases at a much more rapid rate than the demand for other products of mineral oils. Thus it is quite possible that, even with an almost unlimited petroleum supply, there may some day be a gasoline famine.

HOW THE MAGNETO IS UTILIZED FOR IGNITION

By CHARLES B. HAYWARD.

IN recent issues of *THE AUTOMOBILE* the various sources of electric current for ignition, as employed on the car, have been touched upon generally, and the why and wherefore of the dry cell and the accumulator dwelt upon at some length. The latter are the only chemical means of producing a current employed for the purpose on the automobile, the remaining class

is alternating and rises and falls twice during every revolution of the armature; at a certain point in each half turn the current reaches its maximum value or peak, and it is at these points that it is desired to utilize the current for ignition. By maintaining the armature winding short-circuited until these points are reached, the value of the current is still further enhanced when the circuit is suddenly opened. This is done by a mechanically operated circuit breaker, usually a cam fastened to the armature shaft itself, the latter being timed to coincide with the occurrence of the point of ignition in the cylinder.

But by adding a single essential the magneto just described may be readily converted into what has erroneously come to be termed a high-tension magneto. Instead of using the current for ignition as it comes from the magneto, it is sent through an induction coil, or step-up transformer, and raised to a high potential. It is then used in connection with the regulation jump spark plugs instead of with mechanical ignitors, as are necessary in the former case, so that what is commonly known as a high-tension magneto is merely one of the low-tension type with an induction coil. Technically speaking, it would be just as correct to term an accumulator low tension when used with an ignition system of this type and high tension when used with the latter. However, it is difficult to find a term that expresses the characteristics of the magneto in question in a word or two, and popular usage calls for short and easily remembered names, so that this one has stuck. Where one wishes to be explicit in the matter, it is sometimes referred to as "high tension, with coil." The Eisemann and Remy are familiar types.

The difference between this and the true high-tension magneto may most readily be explained by stating the latter incorporates an induction coil in its make up. The armature winding already referred to is made to serve as the primary winding of the coil besides performing the function of generating the current. A condenser completes the transforming part of the apparatus, the current collecting and circuit breaking devices remaining the same—that is, in principle, as they naturally differ materially in the various makes of machines on the market. However, it is

FIG. 1.—Illustrating cycle of an alternating current.

of current producers being purely mechanical, such as the small direct-current dynamo and the magneto. It is intended to take the latter up in the present article. Before doing so it may be as well to correct what appears to be a prevailing impression on the part of a very large number of autoists that the magneto is something of comparatively recent origin, which is finding itself in the first stages of its development on the automobile. How erroneous this is need hardly be called to the attention of those who are at all familiar with the past history of mechanical means of generating an electric current. Far from being a late development in this field, the magneto represents one of the earliest steps in the evolution of the alternating-current generator, but unlike so many other devices which have lost all semblance to their original in the course of improvement, the magneto is the same to-day fundamentally as it was when first invented. Probably the field in which it has met with the widest acceptance is that of telephony, where it has served faithfully for more than a score of years.

How Magnetos Differ.

There is another point that has proved extremely puzzling to a very great many autoists who are not familiar with electric machinery, and that is the real distinction between the low and high-tension types of magnetos. This arises principally from the fact that to a certain extent the terms are interchangeable. To start with the rudiments—and a clear conception of the matter can be gained in no other way—it will be well to recall what has already been given in the general outline of the magneto in a previous issue of *THE AUTOMOBILE*. That is, the nature of its components—a permanent magnetic field and a Siemen's or H-shaped armature. In what may most aptly be termed the true low-tension type, the wire on the armature consists of but a single winding, and usually with comparatively few turns of rather coarse wire, as the voltage required is low. Its sole remaining essential consists of the current-collecting apparatus. As has already been explained previously, the current generated

FIG. 2.—Simplicity of the wiring of low-tension systems.

not intended to go further with the description of the high-tension system at the moment, as this will be gone into more at length later on and in a separate article. The low-tension magneto was the stepping stone in this field and hence will be taken up first.

Characteristics of the Current.

Just how the magneto generates an electric current has already been explained at some length in a previous article, and need not be recalled here further than to bring to mind the fact that, if provided with the usual collector brushes, it would deliver an alternating current constantly as long as turned, as is the case when the crank of a telephone magneto is turned. As the

FIG. 3.—Wiring diagram, "high-tension-with-coil" system.

four-cycle, four-cylinder engine only requires two sparks per revolution for ignition, it is desired that the peak of the alternating current should coincide with the occurrence of these sparks in the cylinder in order to utilize the maximum value of the current at as low an r. p. m. rate of the magneto as possible. A slight digression is doubtless in order here to render clear exactly what is meant by the *peak* of the current wave and the reason for terming it thus. As its name indicates, an alternating current is one that surges back and forth, alternating in direction constantly. These pulsations are termed cycles, and large machines in power plants are wound to give anywhere from 25 to 100 or more cycles per second, known as the *frequency* of the current; this is so high that in electric lighting no flickering whatever is apparent, but when reproduced by a recording instrument they appear as a series of peaks rising and falling to the same distance above and below a horizontal line, which may be termed an "electric dead center." In Fig. 1 the magneto armature is shown in positions corresponding to the rise of the current during one-quarter of its revolution; in the first position it is on the center referred to, corresponding to the horizontal line or beginning of the peak, and with its revolution the current line rises, increasing in value, except that the number of steps or gradations are infinitely greater than the few indicated.

How Time of Ignition Is Altered.

The quarter revolution of the armature shown only corresponds to the rise or left-hand side of the peak in the sketch; the right-hand side or drop would occur during the next quarter revolution, and when it again met the horizontal line the armature would be centered once more. On the third quarter of its revolution the current would be represented by a line dropping below the horizontal the same distance as the peak shown, and, returning to the neutral point, the completion of the revolution and the beginning of the next, making a repetition of the peak already pictured. As it nears the upward limit of its travel and before reversing its direction, as indicated by the arrow, the current approaches its maximum value, and it is at this point that it must be utilized in order to give the greatest efficiency for ignition. The theoretically ideal point at which to do this is naturally the actual top of the peak, but as it is necessary to provide for both advancing and retarding the time of ignition, this cannot always be done. In consequence, provision is usually made to rotate the armature through part of a revolution by hand and independently of its drive, or the time at which the primary circuit is opened is altered to correspond; in some high-tension systems, such as the Bosch, this is accomplished by altering the relative position of the secondary distributor. The effect of this is to take advantage of the current either when just approaching the point of maximum value or when receding from it, as indicated by the dotted lines drawn across the upper part of the peak. As the intensity of the magneto current increases proportionately with the speed of the engine, there is usually found to be less necessity for advancing the time of ignition to the same extent as with the

battery, but current practice in magneto design allows a liberal amount of leeway in this respect, without impairing in any way the efficiency of the machine when working at either extreme.

The Different Systems Compared.

In order to render as clear as possible the fundamental differences between the low tension and the true high-tension types of magnetos, the accompanying simple sketches have been prepared. As its name indicates, in the low-tension type the current is used without being put through any preliminary process of transformation, in contrast with either of the high-tension systems, the difference between which has already been referred to. In the latter it is either sent through an independent induction coil or the latter is embodied in the magneto itself. The essentials of a low-tension system are illustrated by the sketch, Fig. 2. There is but a single winding of coarse wire on the armature; one end of this winding is grounded in the machine itself, which also grounds it on the motor when the magneto is attached to the latter, as no insulation is interposed. This simplifies matters to such an extent that but a single lead from the magneto constitutes the entire wiring; the latter is usually led to a copper bar, to which are attached switches corresponding to the ignitors of each cylinder, so that any one may be cut out at will. When the switch is closed it makes connection with an insulated plug inserted in the cylinder, as shown in the drawing.

It is the fact that some high-tension systems employ an outside coil and others do not that probably does most to puzzle the amateur autoist who likes to figure out such things for himself. The essential difference between these two is well illustrated by the accompanying sketches, which, however, are not intended to picture any particular make of magneto, but merely the general principles of the two types as manufactured in current practice for ignition purposes. Fig. 3 shows what may most correctly be described as "high tension with a coil." In order to simplify the wiring to as great an extent as possible, one side of practically every circuit is grounded as there shown; the condenser, indicated by the interlocking lines and connected across the primary circuit, being incorporated with the coil. For greater clearness, but a single plug is shown; in actual practice a distributor on the magneto itself and run at half speed by gearing is employed. The working of the primary and secondary is thus synchronized, the segment corresponding to one of the plugs passing under the distributor brush at the same instant that the primary circuit is opened by the contact breaker.

In Fig. 4 is illustrated the principle of the true high-tension system, of which the Bosch is one of the earliest and best known representatives, one in which the magneto itself generates a high-tension current directly and without the interposition of any auxiliary devices. The winding proper of the armature also serves as the primary of the induction coil, the secondary of which is also carried on the same core. The condenser is likewise embodied in the machine itself, thus making it entirely self-contained. Wherever possible, one side of each circuit is grounded, as mentioned in connection with the foregoing type, and the secondary current is distributed in much the same manner.

FIG. 4.—Wiring diagram of true high-tension system.

LIMITS OF THERMAL EFFICIENCY IN MOTORS*

By DUGALD CLERK, C.E.

THE Institution Committee on the Standards of Efficiency of Internal Combustion Engines, among their recommendations as to the standard engine of comparison for internal combustion motors, recommended that for the purpose of the standard, air—assumed to be a perfect gas having a value of $\gamma=1.4$ —should be taken as the working fluid. For the ordinary four-stroke cycle engine the formula giving the efficiency then was

$$\eta = 1 - \left(\frac{1}{r}\right)^{0.4}; \text{ where } \frac{1}{r}$$

was the ratio of the minimum volume to maximum volume. The committee were satisfied that with good engines, giving their best economy, the actual efficiency divided by the ideal efficiency determined by this standard could be expressed by a ratio which varied between 0.5 and 0.7. This was deduced from separate tests made by Professor Meyer and Professor Burstall. Professor Burstall's tests also showed how inefficient design would decrease the ratio, as in some of his tests means involving greatly increased cooling surfaces were employed to increase the compression, and were found to considerably diminish the ratio. These tests showed further how too high flame-temperature also decreased the ratio. The committee required, however, further knowledge as to the effect of the dimensions of the engine on the ratio, and accordingly they made tests on three engines of 5 inches, 9 inches and 14 inches diameter cylinders respectively, giving 6 i.h.p., 24 i.h.p., and 60 i.h.p. In these engines, taking the mechanical efficiency to be 88 per cent, and calculating the indicated horsepower from brake horsepower, they found that the efficiency ratios were 0.61, 0.65, and 0.69 in the three engines.

Difference Between Large and Small Engines Slight.

The tests showed, therefore, that by bearing in mind the slight changes in the ratio due to differences in dimensions, a close approximation to the best indicated efficiency to be expected from a given compression could be obtained by the use of a factor varying between 0.60 and 0.70, according to the dimensions of the engine. The tests also showed very clearly the small increase in economy of large engines in comparison with small ones, there being only 12 per cent. increase between 6 horsepower and 60 horsepower. The possible efficiency with the actual fluid used in the engine was known to be less than that given by the air standard. The committee considered that a definitely known standard from which the actual efficiency could be deduced by using a multiplier found experimentally, allowing for the imperfections of the engine as well as for variations in the properties of the working fluid, should be adopted until the properties of the working fluid were accurately known. Mr. Clark said he had examined the results of the test made by the committee and had made some further experiments on the large engine used in the test, with a view to finding the true heat distribution in the engine. The balance sheet given by the committee was as follows:

	L.	R.	X.
Exhaust waste.....	35.3	40.0	89.5
Jacket waste	23.5	29.3	25.0
Radiation	7.6	10.0	7.3
B.H.P.	26.7	28.3	29.8
	<u>93.1</u>	<u>107.6</u>	<u>101.6</u>

Every Factor Must Be Considered.

In obtaining this balance sheet the exhaust waste was determined by calorimeter, jacket waste measured, and the radiation includes friction of the working parts. The brake horsepower was determined by rope brake. In order to reason as regarded

properties of the working fluid, it was necessary to know the indicated horsepower, the loss of heat during explosion and expansion, and the heat in the gases at the end of expansion. These quantities were not given in the ordinary balance sheet, as determined above. In the ordinary test the jacket loss was always over-estimated, because some heat which ought to go to the exhaust calorimeter flowed to the water-jacket after the opening of the exhaust valve and all through the exhaust stroke of the engine. The piston friction also would appear in the water-jacket. He had, therefore, attempted to adjust the balance-sheet from data given in the committee's report. Taking the mechanical efficiencies for the three engines, L, R and X, as 0.84, 0.85 and 0.86, the friction percentage of total heat was 5.1, 5 and 4.9 respectively. Deducting this from the jacket waste, corrected values for heat to water-jacket, 21 per cent., 26.8 per cent. and 22.6 per cent. were obtained. Using these values, and reducing to percentage, assuming that the error in total heat was not in the indicated horsepower item, a new balance sheet was obtained:

	L.	R.	X.
Exhaust waste	41.1	37.1	39.9
Jacket waste	} 27.1	29.6	25.4
True radiation			
I.H.P.	31.8	33.3	34.7
	<u>100.0</u>	<u>100.0</u>	<u>100.0</u>

Maximum Possible Efficiency Calculated.

The ideal efficiencies in these engines were practically the same, and assuming that one-third of the heat going to the engine was converted to work, and that the heat loss occurred near the beginning of the stroke, the difference between the jacket plus radiation losses in any two engines should be three times the difference between the indicated horsepower. In the L and X engines this was found to be exactly the case. The jacket waste in the L engine was evidently too low, and on the above considerations should be 34.1. This value of jacket waste for the L engine would give an exhaust waste of 34.1, which was practically the same as that determined by calorimeter. It appeared, therefore, that in the L engine some heat which should have appeared in the water-jacket had been lost. This corrected balance sheet was probably more accurate than that obtained in the test; but there was still some heat found in the water-jacket which should be in the exhaust. The experiments gave no means of determining the amount. The balance sheet, however, gave a method of calculating the maximum possible efficiency of the actual fluid. Adding exhaust waste to indicated horsepower, and dividing indicated horsepower by the sum, possible efficiencies for the three engines of 0.482, 0.473 and 0.465 were obtained. In obtaining these efficiency values, however, it had been assumed that the heat was lost at the beginning of the stroke, and therefore the values were not accurate. If the distribution of heat loss were known, the true adiabatic could be constructed and correct results obtained. To check the results, indicator diagrams which gave the correct mean pressure have been studied. From the composition of the exhaust gases and the charge temperature, the weight of the charge was found to be 0.14 lb. From the diagram the temperature drop from the end of expansion to charge temperature was 1,745° F.

The specific heat of the gases by weight, assumed constant, was 0.185. From these values, obtained from the numbers given in the committee's report, it appeared that 43 per cent. of all the heat of the combustible gases was accounted for in the exhaust. This gave a balance sheet for the X engine:

	Per Cent.
Exhaust waste	43.0
Jacket waste and radiation.....	22.3
I.H.P.	34.7

*Paper read before The Institute of Civil Engineers, London.

The exhaust waste here would obviously be greater if specific heat increased with temperature. From this balance sheet, calculated as before, an efficiency of 0.447 was obtained; with air, the efficiency would be 0.49. These considerations showed the difficulty in using the actual fluid as a standard. In spite of the great labor expended on the experiments, only a rough approximation to the true heat distribution could be arrived at. In 1884 he had made experiments on cooling after explosion in a closed vessel. Many other investigators had since done similar work, but cooling of a cylinder having a moving piston had never been investigated. He made further experiments, and determined the cooling in the X engine. The engine was run at normal speed, and when a charge had been drawn in, the rollers actuating the inlet and exhaust valves were slipped, so that the valves remained shut. The explosion then took place, and the gases instead of being discharged were alternately compressed and expanded. An indicator card gave a cooling curve, showing temperature fall during successive revolutions of the engine. From these cards the mean apparent specific heat of the gases in the cylinder had been deduced, the gases being practically the same composition as those in the committee trials.

The value given increased with increase of temperature, and had been called apparent specific heat values, because certain facts discovered were inconsistent with the change being entirely specific heat change. Calculations, assuming these numbers to be the true specific heats, were, however very nearly accurate. From the cooling curves and specific heat values so determined a balance sheet had been obtained for the X engine as follows:

	Per Cent.
Heat flow during explosion and expansion.....	16.1
Heat contained in gases at end of expansion.....	49.3
Indicated work	34.6

Efficiency of 88 Per Cent. Shown.

Comparing this with that found by the committee, it was seen that the indicated work was the same in both. There was, however, less heat flow during expansion, and more heat in the gases at exhaust. This showed that about 21 per cent. of the heat in the gases at the end of expansion went to the water-jacket during the opening of exhaust valve and exhaust stroke. This was considered a more accurate balance-sheet than had yet been obtained. Calculating the ideal efficiency as before, the value 41 per cent. was obtained. From the values of specific heat given, the adiabatic might be calculated, from which the ideal efficiency would be found to be 39.5 per cent., showing that the actual engine had converted 88 per cent. of the heat which it possibly could convert into indicated work. The new method had been checked by a test of a small Stockport engine in his laboratory, which gave similar results to those given by the X engine. Tables had been calculated showing the ideal efficiencies for different compressions using the specific heat values given, and showed that roughly the air standard was 20 per cent. too high, and that if gamma be taken, 1.285 for the explosion line, and 1.37 for the compression line, the change of specific heat between 1,700 degs. C. and 1,000 degs. C. commonly used in practice was too small to produce much error. More investigation was, however, required before even the apparent specific heat values could be accurately known for the various mixtures used in internal-combustion motors. Much had been recently done, including experiments by Professor Hopkinson, Messrs. Baird and Alexander, and Professor Burstall; but until further knowledge was obtained, the air standard, as defined by the committee, gave the best basis for comparing the performances of different engines. Appendices to the paper showed the method of calculating the suction temperature, charge temperature, exhaust temperature and charge weight, and also the method of calculating the adiabatic and efficiency for varying specific heats.

[ED. NOTE.—The data which the author has been able to compile as the result of the numerous experiments and investigations undertaken will doubtless be found of considerable value, particularly as it comes from an authority of such high standing.]

THE "NIGHTINGALE" AUTOMOBILE WHISTLE.

It is said that the sirens of ancient times were possessed of pleasing voices; in fact, one is given to understand that they sang as attractively as the chorus at the opera, says *L'Automobile*. The sirens placed on automobiles are, on the contrary, like their larger brothers, the steam whistles used on large vessels—organs strident and raucous, whose working is absolutely disagreeable to sensitive nerves. So far as automobile whistles are concerned, they also have the serious defect of being a torture to the ears. The development of these warning instruments should accordingly take the form of an attempt to make them more musical. We have seen the evolution of the trumpet to four for horns, on which may be placed, if not music, at least all the cavalry calls.

To remedy this state of affairs a Parisian house has just brought forth a very simple apparatus which has been christened the nightingale. It is a whistle designed to be blown by the exhaust, the note produced being varied at the will of the chauffeur. As will be plain from the accompanying line sketch of the device, it consists of a cylinder and piston of brass tubing, attached to the muffler of the car, while the protruding end of the piston rod at the other is connected to a cable. Attached to the

HOW "LE ROSSIGNOL" IS MOUNTED AND OPERATED FROM THE SEAT

same cable are two helical springs, the function of the first or right-hand one shown being to keep the piston in its normal position, which corresponds to the extreme end of its outward stroke, the hand lever acting against the spring to draw it out. The second spring shown at the left-hand side of the sketch, normally maintains the escape pipe from the muffler open, being attached at one end to a bracket and at the other to a clapper or cover for the pipe. When pushed forward the lever also draws against this spring and closes the lever at the same moment as the whistle comes into action. In the brass cylinder itself, or body of the apparatus, there are a number of holes, through which the exhaust gases pass to produce the sound. Varying the number of these explains the method used of obtaining a modulated sound, which may be sharp or very deep, depending upon the part of the cylinder the piston is drawn to at the time. The principle is that of the wood and cork whistle, which all of us have had more or less experience in making in the happy days of our boyhood, and the device itself is as simple and easily operated as those shrill toys which required nothing more than a penknife and a modicum of skill for their manufacture. Of course, considerable more study has been devoted to the design as well as the size of the parts, not to mention the materials that enter into the composition of this latter-day boy's whistle, for such it will doubtless prove in the hands of many a chauffeur. It is a signalling device that has the merit of novelty and one which permits the operator to vary its warning note at his pleasure by producing sounds that are more or less harmonious, but which at least will be less disagreeable than the voice of the average siren—something that should not be difficult.

THE IMPORTANCE OF FACILITIES IN TOURING

By THOS. J. FAY, E.E.

It is nearly as disconcerting to possess the car and nothing besides as it is to be in the fix so often described, viz., "to have everything but the car." Indeed, it is one thing to go for a ride on occasions, but it is quite another matter to tour at length in cars as they are usually found, affording, as they do, barely room enough for one's feet—if perchance the feet be not to fit the boots of one Dexter Penasus—outside of the seats.

That touring cars are rarely ever suitable for touring is a fact so thoroughly established that no one takes the trouble to wonder at the entire absence of even the conveniences that might possibly go with a 6x9-foot flat in the district of the "great unwashed." That so barren a thing as a car so full of machinery that it will hold nothing besides is a necessity is proven by the demand for such cars; but that a remedy for such a state of affairs may not be arrived at is too ludicrous to think about for even a single moment.

As a matter of fact, body work has been more or less a bungle, left to its own devices or in the hands of body-makers who, for the most part, miss the "dashboard" and say "giddap" through force of habit; all because "automobile engineers" are busy on the chassis and have but little, if any, time to devote to the design of the body. That this state of affairs can go on forever is scarcely to be believed; moreover, autoists are not the class of men to take kindly to continued neglect. Of course, body-makers are drifting away from the old carriage makers' practise, apace at any rate, although it must be said 'tis a slow motion, just as "drifting" always is. In the meantime the most enthusiastic of the autoists are doing for themselves "quite nicely, thank you."

The body-makers as a class find themselves in a passing strange predicament, for while they are condemned for making bodies heavy, they are censured for not affording space for luggage; and again, the question of "art" or appearance, like a hungry coyote, barks incessantly and presses hot-footed on the

trail. Back of all of these questions is the great matter of filling orders that seem to tumble over each other in a mad concourse, as if indeed the world must soon come to an end and everyone wants a body in which to tuck his soul.

Body-makers are therefore in the odd position of being able to market anything that looks like a body at double the true value of a serviceable body, and so, it must be confessed, they (the body-makers) can scarcely be expected to do more than "make hay while the sun shines," which is probably what they are doing.

There are, of course, a few specialists who devote their time and their skill to fine body-work, and it is to them the experienced autoist goes in quest of bodywork such as will serve a useful end. Such body-makers do very little, if any, of what might be termed "stock" work, but the product of their establishments is said to be "special," for what reason none can tell, for in all fairness these so-called "special" bodies are barely good enough for so-called stock cars. This is not to say the special bodies are inferior, but it is to say the inferior bodies should have no standing at all and the special bodies should be classed as regular. Special bodies are

so very costly, primarily because they are special, and the word implies a license to charge a special price; and again, building but one body of a kind is sure to end in a far higher cost than that which should obtain were bodies duplicated a hundred or say a thousand-fold.

The illustrations accompanying this article are offered as affording an inkling of what an ambitious autoist can do by way of providing comforts and keeping things "under cover."

Fig. 1 shows the car, ready for the road, all neat and trim, with the "chauffeur" on the job. Viewing the car as it stands it is easy to note a tool box under the running board, an extra front and hind shoe on the running board, as well as a fairly commodious "packer" just back of the shoes, but free of the side

FIG. 1.—Car completely and comfortably equipped for the tour.

FIG. 2.—Showing the commodious and subdivided tool box.

FIG. 3.—Interior of packer beneath running board exposed.

FIG. 4.—How space under rear seat is utilized to advantage.

entrance. The opposite side of the car has also a tool box under the running board, as well as a "packer," but no shoes, since, on the right side an entrance to the driver's seat must be held untrammelled.

Fig. 2 again illustrates the same side of the car, but with the drawers forming the tool box under the running board opened up to view, thus disclosing a very commodious, sub-divided space for necessities. In this figure it is plain to note that the side entrance door is not interfered with by the "packer" on the running board, and a glance at Fig 3 will disclose the open "packer" and the use to which it is put.

This view also shows the side chain of the car open to view and an extra chain in the drawer pulled out from under the running board. The autoist thus suggests that an extra sprocket chain is an article of merit, if not a necessity.

Fig. 4 shows how the space under the rear seat is utilized, which space is made to hold two very commodious packers, and the hood or cover on the ground is made to fit closely over the space, thus rendering the hiding place for the packers proof against the weather, besides holding the artistic effect of the car intact. This view also discloses a packer half drawn out—to the side—from under the front seat, besides giving an excellent view of the chest of drawers under the running board on the left side of the car. Fig. 5 shows the two packers on the ground—out of the rear pocket—and the packer half out from under the front seat, while Mr. Ellsworth—to whose ingenuity the whole arrangement owes its origin—serenely views the scene.

FIG. 5.—Commodious rear seat packers exposed to view.

It seems simplicity itself to thus arrange a car and so provide a considerable storage space for touring necessities, but there are many details to take into account. First and foremost, there is a limit to the weight to be borne by tires, and, again, the limit is nearly reached ere any provision is made for the storage of anything. It follows, then, that packers and all such means of storage must be very light, yet ever so strong, for they are bounced about incessantly.

It will also be understood that doors to cover holes and pockets are not easily swung so as not to mar the outward appearance of the body, while secure means of locking is almost past one's ingenuity. Bodies as usually constructed would scarcely lend themselves to the project in any case, since internal bracings and projections of one sort or another would most likely be in the way.

WHY THAT NEW TIRE BLEW OUT.

It frequently happens that an automobilist discovers a small hole on the outside of one of his tires and a very serious tear of the inner fabric, altogether out of proportion with the exterior defect. The defective shoe is shipped back to the factory, followed by a letter not very flattering to the manufacturer. Michelin, the tire manufacturer, says they receive many such, the motorist always declaring that it is the maker's fault, for the tire shows its deterioration in the fabric, while the rubber is hardly worn. The reply that they give is that the tire has certainly burst, but that the burst is the result of a cut from the outside. A little experiment will show this. Take a piece of unhemmed calico or linen and try to tear it. The commencement of the tear is difficult, but once begun it can be continued with little effort. Every draper knows this and cuts the calico with a pair of scissors before attempting to tear it. The fabric employed in an automobile tire has the same source of weakness as an ordinary piece of calico. A cut is made in the rubber, a sharp-edge pebble enters in and exerts its maximum effort on the fabric, not on the rubber. The constant contraction and expansion of the tire as it passes over the road soon causes the fabric to cut, and once cut the split will spread with increased facility until it has reached the extreme limits of the shoe. It is not a case of defective construction, as is so often imagined, but an example of the necessity for carefully examining the surface of the tire at frequent intervals and taking precautions to keep out all foreign matter.

AUTOMOBILE PROSPECTS IN SOUTH AMERICA.

South America as a field for the automobile manufacturer only offers mediocre interest at present, but there are indications of a widening field, according to J. B. Bartholomew, of Pretoria, Ill., manufacturer of the Glide car. Buenos Ayres, Argentina, is the city with the largest number of automobiles in use. They number rather more than 200, mostly of French and English make, with just a sprinkling of American cars among them. The import duty is 50 per cent. and the price of gasoline 60 cents a gallon. The people of the Argentine are energetic and up-to-date and there is every reason to believe that a big automobile trade may be done in their country. Pernambuco is a stranger to the automobile, and with its roughly paved streets offers little encouragement to its introduction. Bahia has two or three automobiles, but is hardly more encouraging than Pernambuco.

Rio de Janeiro has better streets than most South American cities, and possesses fifty or sixty automobiles of French and English make. The country back of Santos has a few automobiles, but none are in use in the city, and with streets in their present condition they are not likely to multiply. Montevideo is a field in which manufacturers' agents might profitably labor. The streets are fairly well paved and the mud roads are not at all in bad condition. Taken all in all, it is evident that the Argentine will for a long while constitute practically the only South American market of importance for the automobile.

LETTERS INTERESTING AND INSTRUCTIVE

The Different Styles of Spring Suspension.

Editor THE AUTOMOBILE:

[676.]—I have never been able to find any extensive comparison of the virtues of the different styles of spring systems used on automobiles, and would appreciate having you direct me to some source of such information, or, failing in that, perhaps you would find it worth while to publish something along this line. A comparison, for instance, between the various systems of using full-elliptics, half-elliptics, side springs, etc., would be very interesting. I am sure, to many others of your readers, besides myself.

Peru, Ind.

H. E. AGNEWS.

This subject is one that never has been gone into as exhaustively as might be desired by many who have the interest of the industry at heart, so it is not possible to do more than help you out with a few generalizations. The fact that several radically different constructions—the full-elliptic all-around, the half-elliptic all-around, the half-elliptic at the front and the full-elliptic at the rear, the half-elliptic at the front, and the "platform" spring at the rear, and the inverted half-elliptic crosswise at the front, for example—all are considerably standardized and capable of giving good service is enough to prove that this particular detail of automobile design will have to be submitted to many a refining process before any single standard can be achieved, if one ever is. The most-used system to-day is, of course, that employing four longitudinally-placed half-elliptic springs, one at each of the four corners of the car. A particular merit, not often mentioned, which is possessed by this arrangement is that of supporting the frame at eight different, separated points. These points are, moreover, in the best designs, spaced in two series of four each along the two sides of the car. In this way the tendency of running over uneven roads to produce frame flexions must be materially reduced, while at the same time a lighter construction is permitted, inasmuch as the stresses are reduced in magnitude to a degree proportionate to their multiplication in number. Four half-elliptics have the further merit of being light and inexpensive for a given duty, so their wide popularity is not to be wondered at. In favor of full-elliptics is their extreme elasticity and their freedom from the necessity for shackling—merits well established as worth while by their wide prevalence in the best horse vehicle practise. Other of the constructions enumerated may be said to constitute compromises between the full-elliptic all-around and the half-elliptic all-around. Thus the full-elliptic at the front and the platform arrangement at the rear supports the frame at seven points, as against four and eight, respectively, for its two chief competitors. The transverse inverted elliptic at the front, in combination with full-elliptics at the rear, produces a three-point support of the frame, thus removing all tendency to distortion from road roughness, but the frame must be strengthened to withstand the increased stresses due to carrying the weight on points that are more widely separated. For any further information on this subject, we must refer you to the spring manufacturers or to the makers of cars.

What American Cars Have Variable Inlet Valves?

Editor THE AUTOMOBILE:

[677.]—Will you kindly publish a list of the American cars and foreign cars sold in America that are fitted with a variable lift to the inlet valves? This method of throttling is so obviously superior to the customary method of throttling the inlet pipe or carbureter, that it should be given a wide publicity and demanded by purchasers of high-grade cars. If you would like a short statement of these advantages, the writer will be glad to furnish them.

Los Angeles, Cal.

ANGELOS.

We do not know of any American cars now on the market that are fitted with the variable-lift inlet valve method of throttling, and, so far as our knowledge goes, the only foreign car sold in this country built on this plan is the Brasier. We believe some of the Renault cars were so equipped in 1905, but it was subsequently abandoned. If you wish to submit an outline of the advantages of this method, we will be pleased to consider it.

Cambering the Driving Wheels of a Car.

Editor THE AUTOMOBILE:

[678.]—Is there any objection to cambering the rear wheels with double chain drive, the effect of such cambering being to twist the chains slightly? If this is objectionable, is there not some way of so arranging the differential that the countershaft can form an angle between its two parts equal to the amount of the camber? Finally, just what are the advantages of cambering?

Litchfield, Ill.

JOSEPH A. KIMBER.

A great many cars are built with double-chain drive and cambered wheels, with the chains therefore slightly twisted as you describe. With sufficiently long and flexible chains, there appears to be no serious objection to such twisting. In fact, any chain drive on an automobile necessarily works with the chains twisted much of the time, whether the wheels are cambered or not, for the effect of all road irregularities that temporarily destroy the parallelism of the rear axle and the countershaft is to twist the chains. And inasmuch as few roads are so smooth as not to produce constant sidewise tilting of the rear axle, it follows that chains are proved to operate, and operate well, despite slight twisting. By placing a special differential on the propeller shaft a number of shaft-driven cars are made with cambered wheels. The same plan can be applied to a countershaft. Cambering is very necessary for front wheels, to facilitate steering by placing the point of support on the ground under where a prolongation of the steering-pivot axis would strike. For rear wheels it probably is less necessary than has been believed in the past, when wheels were more markedly dished than is common practice nowadays. Camber originated with horse-vehicle wheels, as a means of keeping the load-supporting spokes vertical despite the dish, which served to oppose the rigidity of a flattened cone—as compared with that of a plain disk—against skidding or slewing forces.

Some Problems of the Differential.

Editor THE AUTOMOBILE:

[679.]—In reading foreign automobile periodicals, I have recently run across a number of articles on experimental automobiles in which the differential gear is eliminated, its place being taken by clutches, ratchets, or the like. All of the discussion on the subject, though, has been so excessively technical (from my standpoint) that I must frankly confess an inability to grasp its points. Will you please tell me what objections there are to the differential? I had always supposed that the purpose of this was to permit one rear wheel to run faster than the other in going around curves, the outer wheel naturally having to traverse a curve of greater length than that taken by the inner wheel. This being the case, why is not a regular differential gear perfectly satisfactory, it being an evident fact that it permits one wheel to make the required gain over the other, while at the same time maintaining the application of power to both wheels?

Dubuque, Ia.

C. N. HENDERSON.

The fundamental fault with the balance gear, which is the type of differential used on practically all modern cars, is that it differentiates for *resistances* instead of for *distances*, whereas an ideal mechanism for its place would differentiate solely for distance. The effort to drive both wheels, however, while at the same time permitting one to rotate faster than the other, inevitably involves the trouble referred to. Consequently, only when the difference in resistance is proportional to the difference in distance can the differentiating be correct. Fortunately, this is the usual case when both driving wheels are on road surface of uniform character, but if one strikes a slippery spot, while the other is on a dry one, the latter may constitute a non-rotating pivotal point from which a doubly-rapid forward rotation of the other may be executed. Or, in a less extreme case, the wheel on the drier surface may continue to rotate, but at a rate much slower than that of the wheel on the slippery surface. In either case, a serious skid may be produced. Moreover, in turning a curve, the action is not to apply the power equally through both wheels under any circumstances. Either one or both of

the wheels must slip on the road surface in a degree sufficient to equalize their speeds, or more power must be applied through the outer wheel, because its rate of rotation becomes greater while the tractive stress imparted through it remains the same. A growing realization of these deficiencies of the balance gear seems to be bringing a number of leading European engineers to the belief that it can be discarded with advantage in favor of ratchet and clutch devices. With a ratchet, for instance, the equalizing for varying distance always is perfect, but the drive is definitely applied through the inner wheel on curves. And that this may not be as bad as it appears is suggested in the fact that ordinary running is straight ahead, while curves, when encountered, are in one direction as often as they are in the other. In making one complete turn, no matter of what size, the circumference of the circle traversed by the outer wheel always is greater than the circle traversed by the inner wheel by an amount equal to double the tread, multiplied by 3.1416. This, in the case of a 56-inch tread, is about thirty feet further for the outer wheel to travel. In the case of a car without differential or any equivalent, this means (if the slip be divided equally) that each rear wheel (if thirty-six inches in diameter) must slip one and one-half revolutions in making a complete circle, three-eighths of a revolution in making the more usual quarter turn, and so on. A further advantage of the ratchet is that it permits use of an undivided rear axle or countershaft. The elimination of all differentiating means gives, of course, a still more substantial rotating construction, which is in a degree retained if a clutch in each hub is used, sufficiently tight to drive ordinarily, yet sufficiently loose to slip before the resistance rises high enough to abrade the tire seriously.

Air Cooling by Flanges and by Jackets.

Editor THE AUTOMOBILE:

[680.]—Which is generally regarded as the most successful system of air cooling—that using flanges on the cylinder to radiate the heat, or the one in which air is blown through a jacket surrounding the cylinder? With a flanged cylinder, is it not best to make the flanges of copper or some other metal of high heat conductivity, and to finish the surfaces a dead black, to promote radiation? If not, why not?

Pasadena, Cal.

KARL HANFORD.

It scarcely is possible to decide arbitrarily between the two systems of cooling you mention, since both have proved very successful in practical use, and each has a large following of enthusiastic advocates. It is quite possible, too, you know, that there may be more than one way of doing a thing as it should be done. Air cooling by means of flanges proves very effective on numbers of excellent American cars, while the other system, involving the air jacket, demonstrated its merit so far back as on Daimler's first liquid-fuel engine. The best results obtained with both systems have been gained apparently not alone by careful consideration of external conditions, but by also having regard to what goes on within the cylinders. Low compression, for instance, seems to help air cooling, as also does the provision of an auxiliary exhaust port or valve, to drop the terminal pressure of the burned charges very low before permitting any part of them to escape through the regular exhaust valve. Your mention of radiation as a factor in the cooling suggests somewhat of a misapprehension of conditions. While it is true that a heated surface radiates heat in proportion to the character of its finish—dull black surfaces radiating the best—it must not be forgotten that by far the most of the heat removed from a gasoline engine cylinder during the process of cooling is not radiated, but is carried away by convection—by actual contact of particles of air with the heated surfaces. Flanges thus aid cooling simply by affording a greater area of surface for the air to work, but since a given volume of air has a given heat capacity, if this volume can be crowded through the comparatively narrow space of an air jacket, it will pick up a given number of heat units, even though from a less surface. The objection to attached flanges is the impossibility of making a joint between

two dissimilar metals so perfect that it possesses a heat conductivity equal to that of a similar area of the unbroken metal. Because of this consideration, the property of the metal to conduct more heat to a greater area is in a degree offset by the inability to transfer the heat with corresponding rapidity from the cylinder metal to the flange metal.

SUGGESTED IN EXPLANATION OF No. 644.

Editor THE AUTOMOBILE:

[681.]—In regard to letter No. 644. It looks as though this man has a lot of trouble with his carbureter. I think he is looking in the wrong place for his trouble. He has a leaky intake pipe. Some of the gaskets or joints must leak, for when he closes his throttle, he says that the engine misses, which shows that the air is going into the engine some other way than through the carbureter. I think if he will look over his intake pipe he will find the trouble.

D. F. MACARTHUR.

East Boston, Mass.

Editor THE AUTOMOBILE:

[682.]—In regard to letter No. 644, describing "A Puzzling Carbureter Ailment," I have a suggestion to make which might possibly be of service. My car once developed similar symptoms; it skipped when the throttle was closed, but ran evenly as soon as the speed of the motor was increased. In my case, however, the skipping was confined to one particular cylinder. I found the trouble to be caused by a leaky gasket when the inlet pipe joined the defective cylinder. At slow speeds enough air was drawn in at this point to seriously weaken the mixture in that cylinder. At higher speeds this small quantity of extra air was not enough to materially affect the mixture. Now, in the case described in letter No. 644 the skipping occurred in all four cylinders at different times. It might be, then, bearing in mind my experience, that there was a leak somewhere in the main inlet pipe, that is, before it separates to go to the different cylinders. If such a condition existed, partially closing the air inlet to the carbureter at slow speeds would give the proper supply of air, as the writer of the letter discovered. Thus the trouble seems to me more likely to be outside of the carbureter, especially since these carbureters (Schebler) are not prone to this particular trouble, I believe.

Cambridge, Mass.

SUGGESTION.

Editor THE AUTOMOBILE:

[683.]—I have had the same trouble that Dick Willes complains of in No. 644, your issue of March 21. I find that giving the engine a good injection of kerosene oil will help. I take out all of the spark plugs and turn over until one of the exhaust valves is at its highest lift, fill my oil gun with kerosene and shoot half of it at the valve stem, the balance on top of the piston, continuing until all the cylinders have been treated. Then turn over the engine for some time to work the oil well into all the crevices. Then start the engine and while running slowly give the inlet valve stems a dose of the same.

Will advise him to make an extension to the throttle lever to the center of the air inlet, making a hole in the extension at the edge of the air inlet. Make a circular plate the size of the opening of the air inlet with a threaded peg at one edge which pass up through the hole in the extension, and lock nut to hold it in position over the air inlet. The plate can be adjusted to entirely close the air inlet when throttle is closed and opening with it will open the inlet as desired.

Decrease the tension of the poppet valve, and increase the gasoline supply to correspond with the increased supply of air.

Lindsborg, Kan.

A. E. AGRELIUS.

"NUTMEGGER" ON NEW YORK-BOSTON "RACES."

Editor THE AUTOMOBILE:

[684.]—It is to be hoped that you, as an exponent of safe and sane automobilism, will lend your aid to the crusade which has been started against the shameless lawbreakers who take part in the races, alas endurance runs, between New York and Boston. If these fellows do not possess any sense of moral decency or regard for the rights of others, it is high time they were made to, even though it might be necessary to use a club in the process. The run, as everyone knows, was made simply to gain a little cheap notoriety and a free advertisement for their cars. The advertisement which resulted, however, is not of the kind which they sought, as, in this section, at least, it has resulted in much bad feeling and in turning the buying public away from these particular cars. A manufacturer who turns out a car that can lay claim to real worth does not find it necessary to resort to such tactics in order to sell his product.

Every automobilist knows that in the past it has been necessary to fight the unfair restrictive measures which are yearly proposed in the legislatures of the different States, and now that he

has succeeded in obtaining some rights that even the country constable is bound to respect, he finds them jeopardized by a few narrow-minded speed cranks. The legislature of the State of Connecticut is in session, and the effect of this race on the minds of the legislators will be anxiously watched by those who look upon automobilism as an elevating recreation. The unfortunate part of it is that these racers do not suffer for their misdeeds. They go by with a rush, and are out of harm's way before the authorities awoken to the fact that the law has been flagrantly violated. Then the next fellow, who, wishing to leave business cares behind, to get a breath of fresh air, to enjoy the scenery and to see the country as God made it, with every intention of obeying the spirit as well as the letter of the law, is stopped, haled into court and made to bear the burden of an excessive fine, which, by every reason of justice and equity, should be paid by the intentional transgressor. It is to be fondly hoped that the opinion of those who are the actual buyers of cars will be so potent a factor against those manufacturers who indulge in this practice, as to make it, in the future, impossible.

B. E. H.
Norwalk, Conn.

A SIMPLE SOLUTION OF THE PROBLEM.

Editor THE AUTOMOBILE:

[685.]—In a recent issue was given a trigonometrical proof that the descending piston of a vertical engine travels a greater distance during the first quarter revolution of the crank than it travels during the second quarter. This proof was all right, but it seemed to me to either contain typographical errors or else to be so high as to be over the head of an average intellect like mine. I therefore take the liberty to submit a proof simple enough for the average school-boy.

PISTON TRAVEL DIAGRAM.

Let A, B, C, D be the crank pin circle, with O the center of the circle representing the crankshaft. Let A A', B B' and C C' equal each other and represent the length of the connecting rod in top, middle and bottom positions respectively. It is self-evident that if the rod B B' is allowed to swing or revolve on the wrist pin B' its crank pin end B will describe an arc BX, and that the line B' will be equal to the line B'B. This shows clearly that the piston must be as much below the center of its stroke as X is below O, and that it therefore travels in the first quarter of a revolution a distance equal to C X, and can only travel the remaining distance X A in the second quarter revolution. It is also evident that the rising piston will travel the distance A X in the third quarter and the distance X C in the fourth quarter revolution of the crankshaft.

If the exact distances traveled are desired one needs only to know that the sum of the squares of the two shorter sides of a right angle triangle is equal to the square of the hypotenuse, and (since the lengths of B.O. and B B' are known) subtract the square of B.O. from the square B B' and extract the root of the remainder. This will give the length of B' O, which subtracted from B B' or its equivalent B'X, will give the distance O.X., which added to C O makes the piston travel. Further, the distance O.X. subtracted from O A gives the piston travel of the second or third quarters M, and it is quite plain that C X is greater than X A 20X.

C. E. DURYEA.
Reading, Pa.

E. R. THOMAS' CHALLENGE ACCEPTED.

Editor THE AUTOMOBILE:

[686.]—With reference to the challenge issued by Mr. Thomas to Mr. Rolls on account of some remarks of the latter re American cars.

I notice that Mr. Rolls has not been able to accept Mr. Thomas' challenge to pit his British-built car against an American Thomas, but I hope that, as it is a question of superiority, or otherwise, of British products, Mr. Thomas will not be averse to match his car against another British car.

If Mr. Thomas is agreeable (or failing Mr. Thomas any other American manufacturer), I would like to match an Arrol-Johnston car against the American, and suggest that the terms of competition be two or more events, half to be contested in Great Britain, and half in America. The first event to be the International Reliability Trial in Scotland, June 25 to 29, over some of the very worst and hilliest roads in the kingdom, or the International Tourist Trophy Race in the Isle of Man, May 28.

In order to assure the American manufacturer that he will have a worthy competitor, I will remind him that in the six reliability trials since 1900 the Arrol-Johnston cars secured ten awards. In 1905 the Arrol-Johnston won the Tourist Trophy Race (Mr. Rolls' car second), and in 1906, in the same race, the Arrol-Johnston car was credited with fastest time after deducting time occupied for stoppages for tires. The stoppages were entirely a matter of luck, and in no way detract from the performance of the Arrol-Johnston production.

As far as the American events are concerned, any competition giving fair field and no favor will be acceptable to me.

Warrington, England.
ERNEST ARNOTT.

MORE LIGHT ON CURRENT CONSUMPTION.

Editor THE AUTOMOBILE:

[687.]—I notice that there is very little said in regard to current consumption, and the matter has about dropped. The letter which Harrold Brown, of Boston, wrote a short time ago was very comprehensive. I think that it demonstrated that with the ordinary form of timers, not accounting for the lags, etc., that takes place, that current consumption is the same at all speeds. Later you made the statement that it was followed up by a correspondent that current consumption depended more upon the surge that takes place upon the breaking of the contact in the timer than upon the actual time the car runs. Now I beg to call your attention to the fact that the surge does not in any way draw upon the source of the current, but is an induced current that takes place in the primary winding, and is in an opposite direction to the flow of the current from the batteries, therefore it does not draw upon the source, but opposes it, and consequently can in no way increase the amount of current consumed.

I might add for the benefit of Mr. Thomas, of Raleigh, and the gentleman who has the six-cylinder Ford, that it is no unusual thing for one cylinder to get more oil than another, and it can be caused from a number of things, such as the bolt that holds the connecting rod bearings together extending down too far, and kicking up more oil than is necessary; also by loose piston rings; by lack of compression; by poor ignition in one or more cylinders; and various other causes. You cannot, therefore, expect to have the cylinders receive the same amount of oil.

Columbia, S. C.
CLARENCE T. JONES.

HOW TO PREVENT CARBONIZATION.

Editor THE AUTOMOBILE:

[681.]—Referring to letter No. 640. According to this letter, Subscriber has a lot of trouble with his motor carbonizing. This is the trouble most people are having with their motors. You will find on most motors that the cylinder is counterbored out at the top (combustion chamber) a little more than the finished bore of the cylinder. When the engine is set up you will find that the piston comes up past this counterbore, that is, past the finished part of the cylinder about 1-8 inch, and on some motors about 1-4 inch. Every time the piston comes up it wipes off a little oil, and when the explosion takes place it will spread this around the piston head and cylinder top. This oil absorbs the soot or carbon of the dead gases and deposits it on the piston and cylinder. You will also find, that when the motor misses fire much, it will carbonize much faster. The only way to overcome this trouble is to raise the cylinders so that piston will not come up past the counterbore. I have done this on several machines with good results. The cylinders can be raised by fitting a piece of brass under them. I would advise Subscriber to look into his cylinders, and I think he will find the trouble to be as I say.

East Boston, Mass.
D. F. MacARTHUR.

HOW TO PREVENT SOOTING THE PLUGS.

Editor THE AUTOMOBILE:

[680.]—I note in your issue of March 14th, letter No. 631, in which Mr. Royster complains of trouble with his six-cylinder car, in that the spark plugs on the first three cylinders are frequently fouled while the rear cylinders are not. I think the trouble is easily explained by the fact that Mr. Royster is either too exclusive or too particular in his choice of passengers, and does not keep the rear end of his machine sufficiently loaded, that his engine may be level when running, or in other words, the front end of his machine is low, causing the oil in the crankcase to run to the forward end, giving an excess of oil in the front end of his engine.

If this trouble cannot be corrected by carrying more passengers, which, of course is not always practical, or desirable, the front end of the machine will have to be furnished with stronger springs, or blocks inserted between the present springs and the front axle, to raise the front end of the machine the required amount. If Mr. Royster will use "Soot Proof Plugs" he may also overcome a great deal of his trouble.

LEWIS SEARING.

PICTURESQUE CENTRAL OHIO SCENERY NEAR NELSONVILLE.

MISS KATE WRIGHT ENJOYING HER QUEEN CAR.

THROUGH THE HOCKING VALLEY.

By N. J. THEISS.

NELSONVILLE, O., April 1.—Little is known to the autoist of what may be seen on a trip through the Hocking Valley. To strangers the people of this valley have been pictured as supernatural beings, with horns, until travelers have been afraid to venture through this section of the country. This, the center of one of the largest coal fields of the United States, should be a place of much interest to people who have never seen large coal mines. It is a great sight to have opportunity of seeing the "black diamonds" hauled from the hills at the rate of 6,000 tons per day from a single mine. Access may be had to almost any mine, and you will not find a set of people more anxious to accommodate auto tourists than the miners of the Hocking Valley.

At Nelsonville, a city of 7,000 people, and at Athens, of 6,000 population, hotel accommodations are good, the cost for same very moderate. Storage for the machine is not usually more than 25 cents a night. The roads are all limestone pike and generally level. The writer was able to drive from Columbus to Nelsonville, a distance of sixty-four miles, without disengaging the clutch to change from the high gear. An idea of the road con-

dition may be had from the picture in the lower left-hand corner of this page, and also a slight idea of the scenery along the road as you near Nelsonville. In the summer the roads are good from Nelsonville to the Ohio river, thence south in whatever direction desired. Mr. Autoist, take a drive through the Hocking Valley for a change.

MANY NEW PRIVATE GARAGES AT NEWPORT.

NEWPORT, R. I., April 1.—What may be regarded as a reasonably clear indication of the trend of events is to be seen in the fact that many Newport residents are arranging to have automobile garages on their estates next summer and dispense with horses entirely. William B. Leeds, who purchased the Frederick Vanderbilt estate, is selling all his horses and arranging to have the Vanderbilt stables transformed into a garage for six big machines. Perry Belmont, Delancy Kane, Pembroke Clark, Elisha Dyer, Jr., Edward J. Berwind, E. Rollins Mors, Pembroke Jones and a dozen other prominent summer residents are having garages built on their estates. Indications point strongly to the end of the famous Newport driving hour, with the handsome turnouts for which the place has been famous for years.

THE ROAD FROM COLUMBUS TO NELSONVILLE, O.

MR. THEISS AND PARTY FORDING A CREEK ON THE ROUTE

ROLLS-ROYCE SIX-CYLINDER MODELS FOR 1907

THE latest British immigrant, the Rolls-Royce automobile, won popular favor in the old country before invading the new. In the Tourist Trophy race of last year the Hon. C. S. Rolls, driving one of his own machines, defeated the best automobiles of his native land and not a few from France. A few months ago Mr. Rolls came over to this country and left behind him in the hands of Walter C. Martin, of Broadway and Sixty-second street, the American agency under the title of Rolls-Royce Import Company. Only two models are now constructed, both of six-cylinder type, the four-cylinder type which was so successful last year being discontinued.

Standard specifications are 30-40-horsepower model, three pairs of cylinders 4x5 inches bore and stroke, automatic carbureter, centrifugal governor, synchronized ignition by high tension jump spark, two independent sets of accumulators being used. Lubrication is of force feed type. Cylinders are water cooled, tubular radiator, gear driven pump and belt driven fan being employed. Large leather faced cone clutch self-contained to assure concentricity. Sliding gears of selective type are employed, with direct drive on third speed. Propeller shaft drive to rear live axle. Brakes are of internal type on drums of rear wheels and external on large pulley on main shaft. The 40-50-horsepower model has six cylinders cast in two pairs of three. A high tension Simms-Bosch magneto is fitted, there being two independent ignition systems, with both sets of sparking plugs carried in the cylinder heads. Other main features are the same as on the smaller body.

Examining more closely the newer model, the 40-50-horsepower machine, we find that frame is of pressed steel, narrowed in front to give a wider steering angle, wheel base 135 inches and track 56 inches. The frame is carried on longitudinal semi-elliptic springs with a transverse spring in rear. The two groups of three cylinders, 4 1-2 by 4 1-2 bore and stroke developing 48-horsepower at 1200 revolutions, are mounted on an aluminum crank case suspended from the frame by brackets at the rear and a special arrangement of levers at the forward end. The lower half of the crank case is easily dismantlable for inspection. Each cylinder is completely surrounded by a water jacket, there being no two adjacent cylinders without water between them. The crankshaft is a solid nickel steel forging, with big bearings at each end and in the center, provided with an anti-friction lining carried in a phosphor-bronze bush. The valve chambers are placed on the left hand side of the engine, one

camshaft serving to operate all valves. The shaft and its cams are machined out of the solid. Inlet and exhaust valves are of nickel steel and are interchangeable. The induction and exhaust valves are operated by means of rocking levers pivoted at one end and fitted at the other with a friction roller lying between the valve spindle and the cam. These levers are mounted in pairs, one inlet and one exhaust mounted on one base and attached to the crank chamber by studs. This friction roller lever is claimed to do away with the side pressure which is exerted on the lifter slides when cam and tappet rod come into actual contact. A rather unique arrangement is adopted in connection with the exhaust pipes, there being a small expansion chamber to each set of cylinders leading away to the main expansion chamber below the frame.

The Carbureter is carried in an accessible position on the right hand side of the engine, with induction pipes leading away between the two sets of cylinders joining up to the distributor pipe at the center. The apparatus is a special Rolls-Royce design consisting of three parts very easily dismantlable, provided with an adjustable needle valve with a special locking fork. It is warmed by both hot air from the cylinder walls and hot water from the circulating water system.

Ignition.—A gear driven Simms-Bosch magneto is employed on the 40-50-horsepower model, but the engine has in addition accumulators and coil with independent plugs in the cylinder heads. Operated by independent gearing on the right hand side of the engine are the ignition distributor and water circulating pump. The coil for the ignition system and the two switches for the double system of ignition are the only parts of the apparatus carried on the dashboard.

Lubrication System.—Lubrication is assured by a positive feed oil pump skew driven off the camshaft and delivering oil under pressure to the main bearings, and thence through the hollow crankshaft to the crank pins and gudgeon pins. By means of an easily adjustable valve under the pump cover a constant pressure of oil is maintained in the oil leads independently of the oil in the reservoir under the crank chamber to which the oil runs through a filter after dropping from the bearings.

Clutch and Gears.—A leather-faced cone clutch is employed of very large diameter and wide face, and self contained to insure concentricity. The gear box is mounted on a sub frame. Direct drive is on the third speed, a gear drive being the high

ROLLS-ROYCE SIX-CYLINDER, 40-50 HORSEPOWER CHASSIS, WHICH HAS JUST MADE ITS DEBUT IN AMERICA.

INTAKE SIDE SIX-CYLINDER, 30-40 H.P. ROLLS-ROYCE.

speed. The change speed gear is of the selective type, giving four speeds forward and reverse.

Drive is through propeller shaft and bevel gear to rear live axle. The differential casing is a neat piece of work, comparing very favorably in size with any of the best machines of this type. Hess-Bright roller bearings are used in the rear road wheels.

Brakes.—Internal contracting band brakes operated by the side lever are fitted on drums on the rear wheels. On the driving shaft, immediately behind the gear box, is a 14-inch metal drum fitted with a powerful contracting band brake operated by a pedal. One of the features of this is an arrangement by which the brake can be adjusted by hand entirely without the use of tools. A screwed adjustment rod is provided with a thumb nut, and in order that this nut may not slack back after it has once been set, a spring bolt is fitted to a toggle lever by which the brake is operated.

Control is by spark and throttle lever on the steering wheel. Pedals operate clutch and brake, and there is in addition an accelerator pedal. The steering gear is of reversible type with connecting bar behind front axle on the 40-50 horsepower model.

Thirty-four Horsepower Model.—As will be seen from the illustrations, the smaller size Rolls-Royce differs in several respects from the 40-50 model. Differences are to be found in the engine only, the transmission, drive and other parts being the same in both models. It will be noted that the inlet valves are in the head, operated by rocker arms, all valves being operated by a single camshaft. The exhaust is led into an expansion chamber running the full length of the engine and led to the large expansion chamber at the rear of the frame. There is naturally a different arrangement of the inlet pipes, the cylinders being in three pairs. The induction pipes lead up from the carbureter on the center of the engine in the form of a three arm, one pipe going to each pair of cylinders. There is only one ignition system on this model; the sparking plugs are placed in the sides of the cylinders.

EXHAUST SIDE SIX-CYLINDER, 30-40 H.P. ROLLS-ROYCE.

HOW ONE PIONEER BUILDER BLAZED THE WAY.

PORTLAND, ME., April 1.—S. A. Nickerson, a pioneer in the automobile industry in America, is a native of Belfast, Me., and a mechanical engineering expert of national reputation. Last fall Mr. Nickerson decided that he wanted to get back to his native State, and, refusing several alluring offers, took the agency here for the George N. Pierce Company, a firm with which he has been for several years. He went into the employ of the company in 1900 and is an expert in the building of steam cars.

Mr. Nickerson drove the first wagon ever propelled by steam. That was in 1869. It was a crude affair built by the House Bros., who were connected with the old Wheeler & Wilson sewing machine business. Mr. Nickerson was called to their factory as an expert to complete this steam carriage. There was a very strong prejudice against its use in the public streets, and to operate it a special permit had to be taken out. The car complete weighed 5,000 pounds. It had wooden wheels with iron tires, and carried three men, a stoker, engineer and helmsman. In 1871 the old contrivance was torn to pieces. Henry House took the wagon apart, turned it into a farm wagon, and used it on his farm in Connecticut. His brother, James A. House, took the boiler, and some time afterwards heated his house and greenhouse with it. Mr. Nickerson took the engine and installed it in his 45-foot open launch.

Mr. Nickerson's next venture in the motor carriage line was in 1886, in another section of the country. He was invited to Massachusetts to assist in building a steam road wagon, which weighed 500 pounds. It would carry one operator, who controlled the entire machine, and one passenger. The power was generated from burning kerosene oil under high pressure by vaporization. The wheels were 48-inch bicycle wheels with seven-eighths inch solid tires. It would make very satisfactory speed on the road, Mr. Nickerson said, but the roads were not at their best then. The public was not then ready to accept a steam road carriage, and the pneumatic tire hadn't come in to make possible a practicable automobile.

In 1895 Mr. Nickerson was again called in as an expert in the building of a steam wagon, and in 1899 went to Chicopee Falls, Mass., to complete for the Overman Co. the first Victor road steam wagon. Then in 1900 he went to Buffalo with the George N. Pierce Co. He built five steam cars in competition with David Ferguson, the present designer of the Pierce Great Arrow, and in a test of one year the gasoline car won out against steam and Mr. Nickerson immediately turned his attention to gasoline carriages and has been following up that line ever since.

DETROIT RATES ITSELF HIGH AUTOICALLY.

DETROIT, MICH., April 1.—Detroit is far from being a cheap town when anything in the automobile line is at stake. She may not warm up to general sport as do some of the other large American cities, but when it comes to anything in the auto line Detroit enthusiasts are always there. This was evidenced by the large crowds which turned out during show week, in spite of the fact that the ante had been raised from two bits to half a cart wheel. While afternoon attendances were scarcely as large as those of last year, the evening throngs made up for the deficiency. If further proof is needed to show that Detroit is there on the automobile stuff, a little reflection on the vast number that flocked east to the Vanderbilt cup race, and again to the New York and Chicago shows, should convince.

A NATIONAL FEDERATION OF CHAUFFEURS.

LOUISVILLE, KY., April 1.—Through a special delegation from the Chauffeurs' League of Louisville to the Chauffeurs' League of Chicago arrangements were made for the organization of a National Federation of Chauffeurs' Leagues, with Louisville as the headquarters of the movement. The Executive Committee has decided to hold the national convention of chauffeurs in New York City during show week next winter.

SIMPLICITY OF ATLAS TWO-CYCLE RUNABOUT

A PART from the very prominent part that the automobile played during the course of the San Francisco fire and directly after it, the latter disaster was one that in turn was responsible for a development in the automobile industry. For four years preceding the combination of earthquake and con-

ward and reverse, and the bevel drive and differential on the rear axle being the only mechanism visible on the entire chassis. With but five moving parts, the motor is extremely quiet and smooth-running. Particular attention has been paid in the design of the motor to making every moving part as free from the necessity of adjustment as is possible, so that the motor seldom has to be dismantled, though this is a very simple operation. The crankshaft journals are case-hardened, ground and polished, bronze bearings being employed—a combination that will run for a long while with no perceptible wear. The construction of the crankcase permits of making it air-tight, without the use of stuffing boxes, which is an important advantage in this type of engine. The motor's speed range is from 100 to 2,000 r. p. m. and the transfer of the charge to the combustion chamber is so perfectly

COMPONENT PARTS OF THE ATLAS MOTOR.

flagration that all but wiped the Pacific Coast city off the map temporarily, the Sunset Automobile Company of San Francisco were building a successful little car with a two-cylinder, two-cycle engine under the same title as that of the company—the Sunset. But the fire wiped out the company's plant and its misfortune led to the acquirement of the right to manufacture the car, besides obtaining the services of its designer, Dorville Libby, Jr., by the Atlas Motor Truck Company, of Springfield, Mass. Prior to this, however, the latter concern had put the Atlas motor to the test during a period of eighteen months and accordingly knew exactly what its capabilities were.

The little car was shown publicly in the East for the first time at the show in the Grand Central Palace in December last, where it attracted considerable favorable comment, as did also the huge commercial trucks shown together with it and using the same type of motor. The extreme simplicity of the latter, which means primarily the small number of its components, and particularly small ones that are conspicuous by their absence, may be taken in at a glance upon reference to the accompanying illustration of the complete power plant dismantled, showing its make-up. The latter consists of the one-piece crankcase, the crankshaft, cylinder castings, pistons, piston rings, connecting rods and wristpins, this practically completing the inventory. It may readily be imagined that, starting with a motor as simple as this, the designer would make every effort to carry out the same idea in the remainder of the car, and such has been the case. To realize the extent to which he has succeeded in doing this it is only necessary to glance at the plan view of the chassis as presented in connection with that of the motor. It would be difficult to conceive of anything simpler than this. The motor—disproportionately small by comparison with others of its power—the flywheel, change-speed gear of the planetary type, giving two speeds for-

ATLAS CHASSIS AS SEEN FROM ABOVE.

accomplished that a remarkable increase of speed may be obtained merely by advancing the time of ignition. This makes the motor very flexible and gives a wide range of speed to the car without the necessity of dropping to the low, the use of which is mainly confined to getting under way.

A STURDY REPRESENTATIVE OF THE POPULAR AUTO.

DETAILS OF THE HATFIELD BUGGYABOUT.

On reviewing the specifications of the Hatfield Buggyabout there can be no doubt that its designer has reduced the automobile to its very lowest terms where fewness of parts and liability to accident is concerned. It could not possibly have less, and still constitute an efficient self-propelled vehicle. The details of the entire power plant may be taken in at a glance as pictured in the accompanying illustration. A double-opposed horizontal, four-cycle, air-cooled motor rated at 12 horsepower is placed transversely across the body under the seat, but is so located as to be very accessible in every part. The flywheel is at the rear and its smooth face is designed as one of the members of the friction type of transmission employed. The friction member of the latter is carried on a substantial countershaft supported by liberally proportioned bearings and is arranged to slide back and forth on this shaft on large keyways. In fact, all the parts are designed to withstand the hardest kind of usage and are constructed of materials insuring long service.

No clutch or other disconnecting device is employed, the transmission being further simplified by its elimination. A differentially acting reverse sprocket on which the builders hold patents is placed at each end of the countershaft. This is a simple and positive ratchet device driving in either direction according to the direction of rotation of the friction member. The motor control is sensitive and permits of a considerable range of speed without resorting to a change in the position of the drive. In connection with both the suspension of the body and the chains, there is fitted the Hatfield shock absorber, which performs the offices of dampening the jolts and automatically keeping the chains taut as well as in the correct alignment at all times. Wheel steer, mounted on a vertical steering column, is employed. At its lower end the column carries a pinion engaging a semi-circular rack, to the ends of which the front axle is attached—a type of steering gear made familiar by years of use on fire apparatus.

SIMPLICITY OF THE "WORKS" OF THE HATFIELD.

HANDY AND EFFICIENT 1,000-POUND DELIVERY WAGON.

THE CARTERCAR COMMERCIAL VEHICLE.

Upon the same chassis which serves as the foundation of the runabout, folding tonneau and regulation touring types of the Cartercar, the builders of the latter have, for some time past, been specializing a medium capacity delivery vehicle. That the former lends itself admirably to the requirements of such service is evident from the size of the body that may be used as well as the convenient placing of the power-plant, which in no way interferes with the disposition of the load carried and permits of reaching every part of the mechanism without trouble when the body is full.

This wagon has an effective carrying capacity of 1,000 pounds, and is equipped with the 20-24-horsepower, two-cylinder, horizontal-opposed motor placed transversely on the forward end of the frame under the bonnet, the same as the regulation pleasure cars of this make. All the small parts of the motor mechanism are placed on top of the latter, making them easily accessible. The well-known type of friction disk drive specialized on cars of this make is employed, the shaft carrying the friction disk being attached directly to the motor flywheel, thus eliminating the usual clutch, while the drive itself does away with a change-speed gear box and its troubles. As will be evident from the illustration at the foot of the column which pictures the power plant and transmission complete, the countershaft carries a spoke wheel the periphery of which is shod with the friction surface to engage the large revolving disk against which it is pressed. The relative positions of the two by means of which a wide range of speed is obtained in either direction, are changed with the hand lever shown. This single lever gives all the gradations from zero to the highest speed as well as the reverse, which is also utilized when occasion requires as a brake, in which rôle it is said to be extremely effective and sensitive. On the whole, the car is very simple and efficient, which means reliability and freedom from accident in inexperienced hands.

COMPLETE POWER PLANT AND TRANSMISSION OF CARTERCAR.

FOR AND ABOUT THE GRAND PRIX

PARIS, March 26.—There is bustling activity both at the Automobile Club of France and in the reserved quarters of the different factories where racers are being built for the Grand Prix. The Sporting Commission, which is supreme authority in all that concerns the French club's speed contests, has definitely decided not to construct a banked turn at the Dieppe corner of the circuit. At this point the road is V-shaped, the angle of the V pointing towards Dieppe. A building stands on the edge of the turn, on the inner side of the circuit, and to avoid this difficult corner altogether it was proposed to make a special wood track, joining up the two arms about fifty yards from the fork. The cost would have been about \$3,000. After much consideration, the Sporting Commission has decided that it would not be advisable to turn the circuit into an artificial racing track. Banked up, the turn could have been negotiated at sixty miles an hour; in its natural condition it will have to be tackled at a very slow speed.

The main grand stand and the press stand will be built between the main road and the side track on which will be established the tire and gasoline stations, and from which the Sporting Commission Cup racers will be started. They will thus be on a kind of island, for the loop track will be as rigorously closed to the public as the main course. A tunnel will give communication with the outside of the circuit. Opposite the stands will be very large scoring boards, placed obliquely so as to be visible from all the stands. A new feature will be the placing of Venetian masts at regular intervals along the road in view of the grandstand, to allow the public to calculate the speed of the competitors as they rush by on the fastest stretch.

Darracq Engages Caillois as Race Driver.

Gustave Caillois, who is well known in America on account of his connection with the Thomas firm in the last Vanderbilt Cup race, has signed an engagement with the Darracq Company to drive in all the principal events of the year, and will doubtless represent that firm, together with Wagner and Hanriot, in the Grand Prix. Caillois has long been recognized as one of the most skillful drivers that France possesses, but it is in connec-

tion with the famous Brasier team of the last two Gordon Bennett races that he is best known to the public. Only a few weeks ago he severed his connection with the Thomas company.

Training on the circuit is a daily affair, Albert Clement and Garcedt on Bayard-Clement racers being particularly active. Stricker, who will have charge of the Porthos racer, has set out for a run to Rome and back as a preliminary training. Two of the three Renault racers intended for the Grand Prix are now ready and will make their first run on the Dieppe circuit before the end of the week. As last year, Szisz will be the head of the racing team. The machines will be given a preliminary tryout of about three days.

Two of the three motors which will drive the Panhard-Levassor racers will be tried out on the *Panhard-Tellier* and the *Rapière*, two of the motor boats taking part in the Monaco meeting to open on April 1. As soon as the motor boat races are over, the engines will be put on the chassis now being built and prepared for the 30-liter road race.

Lorraine-Dietrich is building three distinct classes of racers this season. Two are for the Targa Florio, two for the German Emperor's Cup race and three for the Grand Prix. The lack of uniformity in European races makes this multiplicity necessary.

ARDENNES RACE UNDER NEW CONDITIONS.

BRUSSELS, March 27.—The Automobile Club of Belgium has abolished the old weight limit for the Ardennes race to be run on July 22 on a 53.2 miles circuit, starting from Bastogne, to be covered seven times, giving a total of about 372 miles. New conditions are: Cylinder capacity, 8 liters; minimum weight, 2,585 pounds, including racing body and tires, but without tools and spare parts. Gasoline of 690 degrees will be furnished by the racing board. Dismountable rims can be used. There will be no controls; each firm may establish its own tire and spare parts stations. Three machines may be entered from any factory at a cost of \$500 each up to May 15 and \$800 until July 1. Starts will be given at intervals of one minute from 6 A. M. No European race is now run under the old 1,000 kilos weight limit.

THE 1907 SALON DE L'AUTOMOBILE

THE first auto show ever held in France, or, more correctly, the first exhibition at which automobiles were exposed, was opened by the President of the Republic at the Palais de l'Industrie, Paris, in December, 1895. The first automobile Salon to be organized by the Automobile Club of France was housed under tents in the Tuileries Garden, in June, 1898. The one to be held this year is thus the tenth in an uninterrupted line of succession. Each year the Paris Salon has become more and more brilliant, and during the last two years has been, without a doubt, the largest, most artistic and most luxuriously decorated of any trade show in the world. The next show, to be held during November and December, will be a decennial worthy of the national industry. Although yet far in the future, Gustave Rives is at work on the great event and has already published the detail regulations. The show will last twenty days instead of fifteen as in recent years.

The 1907 Salon will be held as usual in the Grand Palais, with a temporary building, probably on the Esplanade des Invalides, for the commercial vehicles, machine tools and motor boats. The Avenue des Champs-Élysées, the Place de la Concorde, including the Automobile Club of France, the Alexandre III bridge, the Esplanade des Invalides and the Place de l'Étoile will all be brilliantly illuminated. These avenues and squares comprise the

finest that Paris possesses and will be illuminated in a manner that has not been equaled since the visit of the Russian Emperor to Paris on the occasion of the inauguration of the Alexandre III bridge across the Seine. The exhibition, in fact, will be a huge national automobile demonstration.

Request for exhibiton space in the Paris Salon must be made not later than August 15. Positions will be granted by the drawing of lots on September 1. Requests for show space received after August 15 will only be considered if any space is available after satisfying early entrants. Following a now established custom, a central portion of the hall will be reserved to a limited number of the oldest and most important French houses. The central stands will have a maximum area of 80 meters, at a rental of \$2,000. Other stands on the ground floor vary in price from \$20 to \$5 per meter, according to position. Space in the galleries will cost four or five dollars a meter, according to position. These prices are for bare floor space, and include neither flooring nor carpets. Each stand must be decorated at the cost of the exhibitor to harmonize with the general decorative scheme of the hall and subject to the approval of the committee. Many of the stands will be marvelous examples of illuminated wrought-iron work, costing amounts frequently double the price of the high rental.

OBLONG FILLER OPENING ON THE B-L-M TANK.

LITTLE THINGS THAT SOMETIMES LOOK BIG.

Little things have the power of making life either a burden or a pleasure, and this is true in automobiling as well as in other pursuits. Many automobile manufacturers show a keen appreciation of the fact in the minor improvements made about their machines. An example is seen in the B-L-M starting crank and the radiator filling cap, both of which are here illustrated.

The crank is so arranged that though it is a fixture in so far as it cannot be taken from the car, it is held flat against the radiator when not in use, instead of projecting threateningly forward like the ordinary fixed crank. The crank turns in a sleeve which is so pivoted that it can swing vertically, carrying the crank with it. The crank has a longitudinal sliding movement in the sleeve, so that when the latter is brought to a horizontal position, in line with the crankshaft of the motor, the crank can be pushed toward and into engagement with the motor shaft. A pin holds it in this position, as if it were a fixed crank, though the usual pin-and-notch arrangement is provided to prevent the crank being carried around by the shaft after the motor has started. When the motor has picked up and the crank is no longer required, it is first slid out of engagement by drawing it away from the crankshaft, when it can be swung up flat against the radiator, the swiveled sleeve holding it and preventing its removal from the car. A pair of brackets with deep notches into which pins on the crank are allowed to drop, holds the crank in the position shown in cut.

B-L-M 24-HORSEPOWER TOURING CAR.
Showing folding crank turned up against the radiator when not in use.

It is no joke to try to pour a bucket of water into a small round hole at the top of a radiator, not only is the process slow and bothersome, but water is often slopped over the ignition apparatus, causing short-circuits. The B-L-M filler is a generous oblong opening that will easily swallow the wide, thin stream of water poured from a bucket without slopping or loss of time. A heavy brass cover, fitted with a gasket to prevent leakage, is held down when closed by a single lever which turns down over the cover, pressing down a cam on a lug on the edge of the cover and firmly closing the opening. It is the work of but an instant to open and close this filler, and there are no threads to stick or refuse to catch and no loose top to get lost—or to drop suddenly when found to be unexpectedly hot.

LOCOMOBILE PROMINENT AS NEWS DELIVERER.

It seems fitting that the Locomobile should be one of the first gasoline cars to be identified with the rôle of newspaper delivery wagons in this city, as it was in a former incarnation—the little "teakettles" of several years ago that the steam cars of the same name first usurped the place of the madly tearing horses and equally wild drivers intent upon delivering extras and early

BROOKLYN "EAGLE'S" NEW LOCOMOBILE DELIVERY CAR.

editions who have so long been a feature of metropolitan life, and one that is dreaded by the pedestrian. The accompanying photograph shows the modern successor of the little steam wagons. It is a 22-horsepower Locomobile chassis of the model of 1907 fitted with a special body by the I. S. Remsen Manufacturing Company, of Brooklyn, and is employed in the service of the Brooklyn *Eagle*. The car is said to do splendid work in its new field, as well it may, and will doubtless prove to be the forerunner of many others for similar work.

USED A CIDER KEG AS A COOLING SYSTEM.

That there are many things which may happen to a car without putting it out of commission if a little ingenuity be exercised, was well proven by a rural autoist in Michigan during one of the cold snaps of the past winter. He was located eight miles from the nearest repair shop and one night the radiator of his car froze solid. He wished to use it the next morning, but did not care to run the risk of increasing the damage, so he rigged up a home-made cooling system. A cider keg full of water was placed on one of the front seats and a piece of garden hose led from it to the cold water intake of the cylinder jackets. The drain cocks of the latter were opened sufficiently to let the water drip out of them fast enough to keep the engine cool, so that the trip was made successfully, and another "useful hint" added to the breviary of the automobilist.

PROSPECTS FOR TRADE IN RUSSIA.

Commercial vehicles are likely to meet with much success and motor boats might be extensively employed on Russia's vast river system. All the difficulties incidental to the establishment of a new industry will be felt by pioneer automobilists in Russia; in addition, the customs authorities do not facilitate matters, and free circulation either within the country or about the frontiers is not always possible.

Notwithstanding, European manufacturers are resolved to do business in Russia. French firms already having agencies in that country are Darracq, Renault Freres, Bayard-Clément, and Chenard & Walcker. Oldsmobile is, we believe, the only American firm which has attempted to trade with Russia. In view of the low temperature prevailing for the greater part of the year, air-cooled cars are likely to meet with special favor, and it is here that American manufacturers might steal a march on European builders. In addition to the firms already having agencies, the following important houses have decided to exhibit at the St. Petersburg show: French, Lorraine-Dietrich, C. G. V., Mendelssohn, Panhard-Levassor, Delaunay-Belleville, Berliet, Mors, Sizaire & Naudin, Cotton-Desgouttes, Labourdette; Belgian, Minerva and Franeau; Italian, Fiat, Bianchi, Standard and Turckheimer; German, Mercedes and Adler.

SERVITOR RUNABOUT, 20-H.P. AND AIR COOLED

ATTRACTIVE NEWCOMER FROM SANDUSKY, O.

Under the title of the "Servitor," the Barnes Manufacturing Company, 1400 Columbus avenue, Sandusky, O., are placing on the market an attractive runabout of the speedy type which combines a number of novel and commendable features. Taking as its motto "A car for service," its designers have striven to eliminate every feature that could possibly tend to reduce the factor of reliability in service and have succeeded in producing a car which should ably substantiate its apt title. For instance, its 20-horsepower engine is air-cooled, thus relieving it of considerable of the usual burden, while the gearless transmission is employed, thus making the car extremely simple to operate and with no risk of damaging it on the part of an inexperienced driver. The foundation of the chassis consists of a pressed steel frame of standard channel section, mounted on well-proportioned semi-elliptical springs front and rear. Drive is by means of propeller shaft and bevel gearing to the live rear axle. A round bonnet shelters the motor and its lines blend well with those of the two-seated body finished in red upholstery, the shape of the mud guards also being made to harmonize.

PETROLEUM ENGINES FOR THE FRENCH NAVY.

For some time a Commission appointed by the French Government have been inquiring into the question of the possible use of petroleum engines in the French Navy, says *Engineering*. After completion of their tests, the Commission have recommended the adoption of the Cazès and the Mietz and Weiss systems and the sets of engines on which the tests were made have been purchased by the Government.

MORS 17-HORSEPOWER CARRIAGE FOR TOWN USE.

AN AUTO FOR TOWN SERVICE.

King Edward of England has added to his automobile "stable" one of the new 17-horsepower Mors town carriages, with motor under the seat. Automobiles specially designed for town service were a special feature of the last Paris salon, and among the many excellent chassis exposed the Mors occupied a high position. King Edward was so pleased with this little machine that he purchased it on the spot, declaring that the fittings and upholstery were all that he could desire. One of the distinctive features of this machine is the ease with which it can be turned in the narrowest of streets and in the most crowded thoroughfares. Cryder & Company, American agents for the Mors, Broadway and 63d street, New York City, state that society leaders here are placing numerous orders for this type of the Mors for town use.

A MICHIGAN AUTO CITY THAT THRIVES.

PONTIAC, MICH., April 1.—In three short years our automobile industry of Pontiac has sprung from nothing to a point where 400 men are now employed, and with the completion of additions to the two auto plants here the number of workmen will be increased at least fifty per cent. The two plants here are those of the Rapid Motor Vehicle Company and the Welch Motor Car Company. The Rapid Motor Vehicle Company, which a year ago moved into its new building, now has plans for an addition, 60x150 feet in size and two stories high.

FRANKLIN TYPE J TRUCK AND ITS BIG LOAD.

This is the car on which the H. H. Franklin Mfg. Co. has been giving the worm-gear drive a most severe test. The tire chains prove very efficacious on the slippery street.

BUSY AUTO CLUBS AND THEIR DOINGS

Quaker City Motor Club Climb Will Be Held on May 30.

PHILADELPHIA, April 1.—The active season of the Quaker City Motor Club will be inaugurated a fortnight earlier than intended in response to the demands of charity. The Ladies' Aid Committee of the Pennsylvania Epileptic Hospital and Colony Farm asked the club to assist at a motor carnival at the Belmont track on Saturday, May 18, and the board of governors decided to accept. The contest committee is already at work on the details of a program including many novelties in addition to the regular speed events. The exact course over which the hill climb will be run has not yet been decided upon, but the contest committee has decided to adhere to its original intention of running off the event on Memorial Day. This action definitely bars City Line Hill from the list of probabilities, the combined opposition of the G. A. R. Veterans, the cemeteries and the horsemen having been too bitter to overcome.

COVER OF MENU CARD USED AT BANQUET OF THE ROCHESTER AUTOMOBILE CLUB, MARCH 25.

How Drought, of Milwaukee Club, Increased Speed Limit.

MADISON, Wis., April 1.—Giving legislators free rides in automobiles has resulted in the killing of a bill in the Legislature regulating the speed in cities to six miles an hour and in the country to eight miles.

James Drought was sent to Madison by the Milwaukee Automobile Club to induce the legislators to take rides and then demonstrate different speeds. They were taken for rides about the city and out in the country. As a result all stringent laws regulating the speed in the country to less than ten miles will be killed. Assemblymen believe fifteen miles would be about right.

Washington Club on Maryland Law Violations.

WASHINGTON, D. C., April 1.—A special meeting of the Automobile Club of Washington was held March 28 for the purpose of taking some action with reference to the constant violation of the speed laws of Glen Echo, Md., located on the Conduit road.

The meeting was largely attended, and while the sentiment was unanimously in favor of upholding the Glen Echo authorities in curbing the speed mania now so much in evidence on the Conduit road, it was equally unanimous against Charles Collins, Glen Echo's Town Marshal, who makes life a burden for the automobilists, whether they violate the law or not.

Chairman Miles Makes Earnest Appeal for the Orphans.

NEW YORK, April 1.—June 12, the National Orphans' Day instituted by the A. A. A., has been fixed by the New York Motor Club as the day when the children of the orphan asylums of the city will be given their annual outing. For the past two years the club has successfully carried out this excellent work and has brought an immeasurable amount of happiness to the little ones. The third event, it is hoped, will be larger and more successful than any of its predecessors. No expense or trouble will be spared by the club to make it so, and if owners of automobiles accord the support which the object deserves it will certainly be a huge success. S. A. Miles, chairman of the Orphans' Day committee, has received offers of a number of cars, but still more are required. Two hundred and fifty automobiles could easily be filled, and Mr. Miles has made an earnest appeal to owners to lend their machines and drivers on June 12. The claims of the orphans only need to be mentioned for true-hearted men to respond willingly and generously.

South Bend Enthuses Over Indiana State Body.

SOUTH BEND, IND., April 2.—The South Bend Automobile Club will take an active part in the formation of the Indiana State Association through its president, John J. McErlain. Since the A. A. A. renewed talking of organizing State bodies throughout the country and Secretary Elliott of the national organization wrote E. C. Briggs of South Bend, telling him of the intention to form a State association in Indiana, there has been an increase in local interest in autoing, and the South Bend club has taken the initiative in bringing about a State association.

The local club will hold a big meeting about April 15, and will at that time outline plans for an extensive campaign. Owing to the many new automobile owners there will be an enlarged membership this season. The matter of local interest in the A. A. A. tour has been turned over by the club to the Tincer Motor Car Company of this city. A canvass of the members of the local organization will be made to get their wishes in the matter, after which a report will be made to the A. A. A.

Rules Adopted for the New Jersey Endurance Run.

NEWARK, N. J., April 1.—Practically all arrangements for the three-day endurance run of the New Jersey Automobile and Motor Club have been completed. The contest will be held May 30 to June 1, is primarily for the purpose of demonstrating the powers of endurance of automobiles, and is open only to members of the New Jersey Automobile and Motor Club. As will be seen by the accompanying maps, the route will be entirely over New Jersey roads and will closely approximate conditions that are met with in touring. Two classes of cars will be scheduled, touring and runabout, and to the winner of the first class will be awarded the Shanley trophy—to the winner of the last mentioned class the Sinclair trophy.

One of the most stringent rules relates to official observers, and states that every vehicle shall carry an official observer, for whom a front seat shall be reserved, and cars shall be under observation continuously, from the time of the start until the close of the contest, either by the observers on the car or the person or persons in charge of the garages. Entrants must nominate one observer in respect to each car entered by them. The name of such observer must be submitted at the time the entry is made. No observer shall act as such upon the car of his nominator, and the committee reserves the right to reject any nominee without giving reasons therefor. Each observer will, so far as practicable, be placed on a different vehicle each day. He must not in any way assist drivers or cars; for instance, he must not turn on

lubricators or perform any functions, however small, in connection with the car. He must not even assist drivers with suggestions as to what to do in case of trouble.

Competing cars must carry a full complement of passengers of an average weight of 125 pounds each, and competitors must

FIRST DAY'S ROUTE OF THE NEW JERSEY ENDURANCE RUN.

conform strictly to traffic regulations and speed laws as provided by the statutes of the State of New Jersey. No stop of a car for repairs or other cause can be made without penalization, save in the event of tire trouble, and competitors on entering assume entire responsibility for their respective cars and the damage which may be done to them during the run.

In the matter of penalization cars must adhere to schedule within five minutes either way to avoid it. The penalizations are points per minute or fractions thereof for the following:

Points per Minute.

- To arrive at any control more than five minutes before or after schedule time 2
To stop car or motor between controls without making repairs or adjustments 3
To stop car or motor to make repairs, adjustments or replacements 2
To make repairs or replacements without stopping motor 1

To have one or more persons render assistance in any way, the time of such person or persons will be charged at double the rate as, and in addition to, that charged against the driver. No penalty will be noted against puncture of tires, but if a puncture occur and the car does not arrive at the control within the prescribed time, points will be scored against the car, as above, for each minute late.

No record will be kept of the amount of oil or gasoline used, but neither must be put into the tanks unless under the supervision of the observer, and then only while a car is in a control.

Entries must be filed with fees on or before the hour of 6 P.M., Wednesday, May 22, with Secretary H. A. Bonnell, 1034 Broad street, Newark, N. J. W. C. Shanley, donor of the trophy for touring cars, will officiate as referee.

SECOND AND THIRD DAYS' ROUTE.

THE AUTOMOBILE CALENDAR.

AMERICAN.

Shows.

- April 6-13.....—Montreal, Canada, Second International Automobile and Sportsman's Exhibition. R. M. Jaffray, manager, 309 W. Notre Dame street.
April 8-13.....—Pittsburg, Pa., First Annual Show of the Pittsburg Automobile Dealers' Association, Duquesne Garden.
April 11-13.....—Denver, Col., Automobile Show, Coliseum Hall, G. A. Wahlgreen, manager.
Oct. 31-Nov. 7..—New York City, Madison Square Garden, Eighth Annual Automobile Show, Association of Licensed Automobile Manufacturers.
Nov. 30-Dec. 7..—Chicago, Coliseum and First Regt. Armory, Eighth Annual National Automobile Show, National Association of Automobile Manufacturers.

Races, Hill-Climbs, etc.

- May 6-7.....—Harrisburg, Pa., Two-day Endurance Run, Motor Club of Harrisburg.
May 30.....—Philadelphia, Hill Climb, Quaker City Motor Club.
May 30.....—Chicago, Memorial Day Race Meet of the Chicago Motor Club.
May 30-June 1..—Newark, N. J., Three-day Endurance Run of the New Jersey Automobile and Motor Club.
June 12.....—National Orphans' Day, instituted by the American Automobile Association.
July 10.....—Cleveland, O., Start of Fourth Annual Tour of the American Automobile Association, for the Golden Trophy. Finishes in New York City on or about July 23.
Oct. 19.....—St. Louis, Mo., International Aerial Race of the Gordon Bennett Prize. Aero Club of America.

FOREIGN.

Shows.

- April 6-13.....—London, Agricultural Hall Motor Show.
May 4-15.....—Madrid, Spain, Automobile Exhibition, Palace of Fine Arts, Royal Automobile Club of Madrid.
May 16-26.....—Zurich, Third Annual Swiss Automobile Show.
June 25-30.....—St. Petersburg, Russia, Automobile Show.

Races, Hill-Climbs, etc.

- April 1-16.....—Spring Wheel Competition, A. C. of France.
April 18.....—Paris, La Coupe des Voiturettes, A. C. of France.
April 21.....—Targa Florio Tour (Sicily), Auto Club of Milan.
April 25-28.....—Touring Contest, Automobile Club of Touraine.
April 28.....—Chateau Thierry Hill Climb.
May 16-31.....—Belgium, Industrial Vehicle Trials, Automobile Club du Nord.
May 18-21.....—Milan, Italy, Touring Club Trials.
May 22-25.....—Irish Automobile Club Reliability Trials.
May 24-27.....—Voiturette Contest, Automobile Club of Austria.
May 28.....—Isle of Man, Tourist Trophy Race, Automobile Club of Great Britain and Ireland.
May 30.....—Isle of Man, Heavy Touring Car Race, Automobile Club of Great Britain and Ireland.
June 3-12.....—Paris, Electric Vehicle Competition, Automobile Club of France.
June 3-12.....—Herkomer Cup, Automobile Club of Bavaria.
June 14.....—German Emperor's Cup, Taunus Circuit, Imperial Automobile Club.
June 20-22.....—American Gold Cup, Start from New York of European Tour for American Cars, Georges Dupuy, secretary, 1402 Broadway, New York City.
June 14-29.....—Scottish Reliability Trial, Scottish Automobile Club.
July 2.....—Grand Prix, Automobile Club of France.
July 14, 1908....—Paris to London, Aerial Race.
July 15-18.....—Ostend Week, Record Trials, Automobile Club of Belgium.
July 21.....—Ardenne Circuit (Belgium).
July 31.....—Liedekerke Cup for Touring Cars, Ardenne Circuit, Belgium.
July 31-Aug. 8..—Belgium Regularity Contest for Touring Cars. A. C. of Belgium.
August 1-7.....—Criterium of France, 1,750 Miles Touring Competition and 250-mile race for the Press Cup. A. C. of France.
August 11-29....—France, Coupe de Auvergne.
Sept. 1.....—Italy, Brescia Circuit, Florio Cup. A. C. of Italy.

Concerning Letters Inter-esting and Instructive. Some of the letters we have received recently for publication under the caption of "Letters Interesting and Instructive" make this a fitting opportunity to comment on the widespread interest this department of THE AUTOMOBILE has been instrumental in arousing on the part of autoists all over the country. Every enthusiastic owner who has the time and opportunity is desirous of mastering his car, but there are many, many things that are only to be learned by traveling the hard road of experience, and help in solving the problems as they come along is naturally much sought after. But there are so many different makes of cars, each with its own peculiarities, that it would be next to impossible to have a knowledge of all of them, and while we endeavor to aid in the solution of every problem that arises, there are naturally frequent occasions when only the man who has an intimate acquaintance with the particular car in question can come to the rescue. Here then is the subscriber's opportunity to benefit himself, and doubtless others in the same predicament, and it is certainly encouraging to note how frequently this is the case through the medium of our correspondence clearing house. Occasionally a reader will take us to task under the impression that we are attempting to pose as infallible oracles in all things automobile. We are not only willing but anxious to be shown so that we can help the next fellow, so that this calls for no comment on our part. Whenever you are in need of information or help in solving a knotty one, write to the editor, and, if in our power, we will try to make things clear; if not, numbers of our subscribers will come to the rescue.

To Be No Dearth of Interesting Competitions. Judging from present indications, few years have opened with better prospects of the holding of a number of interesting contests than the present. Realizing the shortcomings of the 1906 A. A. A. Tour rules, the conditions have been revised in a manner that should be productive of an event far more interesting and instructive than either of its predecessors. Instead of the wild cross-country dash under conditions that savored more of the transfer of an army from one part of the country to another in time of war, rather than a peaceful cavalcade bent mainly on pleasure, there will doubtless be a "touring" contest as near to the realization of the meaning of that term as it is possible to approach under the circumstances.

Where the racing end is concerned, there is little doubt but that what has come to be more generally known as the American automobile derby—the Vanderbilt Cup race—will, under the new conditions imposed, or rather granted, by the use of a restricted road upon which to run it, be an event of far greater interest than was possible under the restrictions necessarily adhered to as closely as possible in former years. Every assurance is forthcoming that, shortly after this, there will be run off, on the same course, a contest for American supremacy that will be of even more vital interest to the American builder than the international event that precedes it. These three, supplemented by numerous club events of a similar nature, should leave little to be desired in the shape of touring and racing competition during the coming season.

Duplicating the Ignition System Finds Favor. Time was when not alone the average autoist, but also the supposedly well-informed designer and manufacturer looked askance at any suggestion of the magneto, and that was not long ago either. Considered from one point of view, there has been little if any change in ignition systems generally during the interim, though in another sense there has been somewhat of a revolution. In other words, there has been no radical change in the appliances and apparatus employed to generate or utilize the electric current for ignition, but there has been an almost complete reversal in the status of the different systems. Taking into consideration current practice as represented by American makers alone, there were but few advocates of the low-tension system of ignition in this country a few years ago; there were even fewer who were disposed to look favorably upon the magneto of either type.

To those who are familiar with this essential as represented on the up-to-date American car, it is hardly necessary to comment at length on the change that has come about since then. During the interval both the accumulator and the magneto have been developed to an unthought-of extent, and the fact has been recognized that regardless of the perfection to which a system may be brought, the best factor of safety is duplication. If any one had had the temerity in 1903 or 1904 to venture the assertion that within a year or two, cars employing both the low and high-tension systems of ignition would be built, he would have immediately been classed as a "revolutionary," meaning one of that type of inventors the product of whose genius is bound to sweep away all existing efforts—in his own opinion.

Regarding the matter of providing an adequate factor of safety, the former "reserve" set of dry cells has undergone a process of evolution which has not stopped short of duplicating the entire system, the most striking examples of this being the use of two totally different systems as just referred to. Two sets of dry cells, an accumulator and dry cells, two sets of accumulators, magneto and accumulator and low tension magneto system and high-tension accumulator system would appear to aptly represent the steps that this essential has undergone in the past few years. In that time, reliability has been made an equally prominent characteristic of this as of other parts of the car, but experience has demonstrated that duplication is excellent insurance.

A. C. A.-A. M. C. M. A. SHOW TO BE EARLY.

As might be expected, the question of the New York show and the plans for the proposed Society of American Motor Car Engineers with the laboratory idea included, occupied most of the time at the Committee of Management meeting of the American Motor Car Manufacturers' Association, held at the New York City headquarters on Friday of last week.

It was announced that definite arrangements had been made with the Automobile Club of America, and the two organizations will work together on the show this fall, to be held as usual in Grand Central Palace. It was agreed that an earlier date than the December one of last year would be best, but no definite time has been decided upon. There are some good reasons for a show following the one at the Garden, coming between it and the Chicago affair, and there are some who think an affair at the same time as the Garden show would have many advantages. The matter will be taken up with all the members of the Association.

Proposals for the testing laboratory planned by the Association were received, but until further investigation nothing will be decided upon in that direction. The officials of the Association wish to investigate thoroughly the requirements of such a laboratory before coming to a decision.

A number of applications for membership were announced by the Membership Committee and will be subjected to the vote of the members.

There was a general discussion over the benefits of the proposed central bureau of good roads which the Association has voted to support both morally and financially.

The remainder of the day was taken up with routine matters. The new Show Committee which is to work with the Automobile Club of America on the show in the fall, consists of H. O. Smith, chairman; William Mitchell Lewis, and J. B. Bartholomew.

In attendance at the meeting were: Benjamin Briscoe, chairman, Maxwell-Briscoe Motor Company; Charles Lewis, Jackson Automobile Company; H. C. Smith, Premier Motor Manufacturing Company; E. F. Peer, Reo Motor Car Company; C. C. Hanch, Nordyke & Marmon Company; William Mitchell Lewis, Mitchell Motor Car Company; Roger J. Sullivan, Wayne Automobile Company, and Alfred Reeves, general manager.

PENNSYLVANIA TO GRANT RECIPROCITY.

PHILADELPHIA, April 1.—Local automobilists are delighted over the fact that after a long fight the House at Harrisburg, on Tuesday last, passed finally the measure providing for the recognition in this State of automobile licenses issued by any other State placing similar legislation on its statute books. They look forward to the time when it will be possible to pass all State boundaries without being compelled to change their tag outfits and select the proper license from the bunch in order to be ready in the event of hold-up by the "inspectors."

What with a universal license of \$1,000,000 appropriated specifically for the improvement of the Philadelphia-Pittsburg trunk-line road, Pennsylvania promises ere long to become the promised land of the automobilist.

DRIVER NOT RESPONSIBLE FOR BURSTING TIRE.

According to a decision of the Court of Appeal, of Lyons, France, an accident caused by the bursting of an automobile tire cannot be held to be imputable to the driver of the machine. Recently, on the road between Gex and Geneva, an automobile driven by a chauffeur in the employ of the Vanderbilt family, overturned, killing a man in its fall. The driver was condemned to six days imprisonment for having caused the death of the man by imprudence. In the higher court the decision was repealed on the ground that the bursting of a tire, which caused the car to overtrun, was independent of the will of the driver.

BAY STATERS FAVOR ANNUAL FEE.

BOSTON, March 30.—Rather a curious spectacle was presented this week at the State House when the automobilists appeared before the committee on taxation and were registered in favor of a bill to increase the registration fee for automobiles in Massachusetts by establishing a sliding scale based on horsepower with a minimum fee of \$5 and a maximum of \$15 for pleasure vehicles. Representatives of the Massachusetts State Automobile Association, Massachusetts Automobile Club, Bay State Automobile Association, Worcester Automobile Club, Springfield Automobile Club, and Automobile Owners' Association all told the committee that they were in favor of the bill, "with some changes." The changes which were suggested amounted practically to opposition to every phase of the bill. The speakers, nevertheless, were recorded as favoring the measure.

The Highway Commissioners say that because of the additional wear on the State roads occasioned by the increased automobile traffic they will need \$50,000 extra appropriation this year for repairs. To obtain this money it is proposed to increase the registration fee, and the bill under discussion this week was the means to that end, it having been figured out that with a graduated fee from \$5 to \$15 the income would be sufficient to pay for the extra repairs required.

In their arguments in favor of the bill the automobilists pointed out first that the measure is impossible as it comes dangerously near being in the nature of a double tax on property, automobiles being taxed primarily in the communities where their owners reside; secondly, that the measure is unworkable, because it is impossible to determine exactly the horsepower of a gasoline motor, and to determine it with any degree of exactness would require much expense and detailed study of every one of the 13,000 or 14,000 machines in the State; thirdly, that the bill is inequitable, because it singles out one class of users of the highways only and makes them pay the bills, while all other users pay nothing; fourthly, that it is discourteous, because under it machines from other States could be driven in Massachusetts only two days without being registered here; and lastly, that it is unnecessary, as the automobilists are already contributing a large sum of money each year to the State treasury.

In place of the graduated fee provision of the bill the automobilists presented to the committee a sort of compromise. They admitted that automobilists use the State highways to a considerable extent, and that undoubtedly the additional traffic shortens the life of these as well as of other macadam roads in the State. Acknowledging this, they suggested that it would be fairer to all parties concerned if the law was changed so as to make the registration fee for an automobile annual instead of perpetual. At present the purchaser of an automobile pays a registration fee of \$2 and this holds good until the machine is sold or worn out. It is estimated that with an annual fee of \$2 for registration and the fees for operators' licenses, the State would receive an additional revenue of from \$25,000 to \$30,000, which, taken together with the usual income, would provide plenty of money for highway repairs.

The Highway Commissioners are in favor of the bill because it saves them from going before the Legislature and asking for a much larger appropriation, something which State boards do not like to do if they can help it. Under the bill all the fees paid in would go to constitute a State highway maintenance fund, from which appropriations would be made for highway repairs. The question was brought up at the hearing of how the park boulevards would be taken care of and the only answer was that if the automobilists were to be made to pay for them, the fees would have to be increased still more than proposed in the bill under consideration.

The hearing this week winds up the automobile legislation for this season as far as parties outside the legislative bodies themselves are concerned. The session has been fairly prolific in proposed measures, and the State Automobile Association's committee has been quite busy.

BRIDGE OVER SUSQUEHANNA THAT WILL BE DOUBLE-DECKED.

DOUBLE-DECKING LONGEST PENN. BRIDGE.

YORK, PA., April 1.—A big improvement for the autoist will be the double-decking of the big railroad bridge which spans the Susquehanna river at Wrightsville. The bridge connects with Columbia on the Lancaster county side of the beautiful but un-navigable stream. For years the hundreds of auto tourists who use this bridge have been obliged to wait on the Columbia side for long periods while trains are passing on the low-grade freight line. The double-decking of the bridge will do away with all that delay and the autoist will be able to cross the bridge at any time and proceed on his way. The upper deck of the bridge will be used by the trolley, vehicles and autos. This leaves nothing but steam cars for the lower deck. The pedestrians will also use the upper deck. During the summer auto season it is not an uncommon sight to see scores of big touring cars cross this bridge in a day. This is the only direct route between New York and Philadelphia to the famous Gettysburg battlefield, just forty miles inland from the river.

The length of the bridge is 1.1 miles and while the majority of the tourists do not make any try at speed when crossing it, several drivers have covered the distance in less than two minutes. Nevin Hench, of this city, one of the youngest, as well as most daring autoists in the Keystone State, recently timed his run over the bridge, and made it in 1.36 minutes. The run was made in a Pope-Toledo, with three other occupants in the car.

Work is to be started on the double-decking of the big bridge at once. The woodwork arrived recently and the iron structural parts have been finished and shipped by a Connecticut firm. The recent announcement that the bridge was to be thus improved, by the Pennsylvania Railroad Company, was received with great interest by the autoists from this part of the State and others who have occasion to cross the Susquehanna at this point will also join in the general praise.

THE AUTOMOBILE IN MUNICIPAL SERVICE.

London authorities are hardly less interested in the use of the automobile for various duties previously performed entirely by horse vehicles than are private firms. The opposite illustration shows an electric police ambulance as used by the police authorities in the city of London. The transformation of vehicular conditions is proceeding at a more rapid rate in the British metropolis than probably any city in the world, owing to the advent of motor buses, motor cabs and special types of automobile vehicles. In Paris the automobile is now used by the municipality for collecting the contents of the household garbage cans, for watering the streets, for sweeping the streets, by the police and fire brigade, and as a hearse. Public transportation service in both London and Paris is now largely assured by gasoline vehicles, London being noted for 'buses and Paris for its motor cabs.

GERMANY'S VARIOUS CUP RACES.

BERLIN, March 25.—The Commission for the Imperial Cup race in June over a course in the Taunus has seen itself obliged to make decisive alterations in the route first chosen, as the long list of entries proved it too short for equal chances to be given to all starters, and as the idea of weeding out a whole row of cars did not find much favor a longer route has been settled on. This is from Kloster Thron to Homburg, Oberursel, Königstein, Glastmetten, Esch, Niederrems, Reichenbach, Riedelbach, Rod a. d. Weil, Emmershausen, Winden, Audenschmiede, Weilmenster, Luetzendorf, Ernesthausen, Essershausen, Weilburg, Eulhaus, Gravenwiesbach, Usingen, Wehrheim, Kloster Thron. Each circuit—there are four in all—is about 125 kilometers in length.

The following alterations have been made in the Herkomer propositions: The Kesselberg and Forstenried rides will be timed in minutes, seconds and fifths of seconds. The Forstenried and Kesselberg rides will be valued by means of a table to be issued later in such a manner that should the car not attain or exceed the speed fixed for it as normal, it will be debited or credited 1-100 point in the flat and 1-200 point on the hill for every commenced 1-10 per cent. By equal points on the hill the result of the flat trials will decide and vice versa, or secondarily, the ballot.

The German Emperor has presented the German Motor Volunteer Corps with a cup for a long-distance race. His Majesty is more than ever interested in military automobilism, and the question of founding a standing motor car division in the regular army is being seriously discussed and is but a matter of time and red tape now.

FORMULAE ADOPTED FOR HERKOMER TOUR.

As a means of placing all the cars to enter the Herkomer Tour during the season on an even basis, the following formulae have been adopted for the rating of the cars which take part in the deciding events of the tour, the speed trials in Forstenrieder Park and the Kesselberg hill climb:

$$X=10 \quad H+43.5 \quad \text{Km/St}$$

The foregoing is for the speed trials. For the hill climb the formula will be as follows:

$$X=6.3 \quad H+21 \quad \text{Km/St}$$

In both of which X= speed in kilometers per hour and H=the total cylinder volume in liters.

TEUTON ENTRANT FOR TOURIST TROPHY RACE.

For the first time in the history of the Tourist Trophy race a German car has been entered to compete. The seeker after honors is a German Mercedes and will have the distinction of being the first of its kind to start in the event.

ELECTRIC POLICE AMBULANCE USED IN LONDON.

WHY THE ROADS OF THE COUNTRY ARE SO POOR

WASHINGTON, D. C., April 1.—Logan W. Page, director of the Office of Public Roads, Department of Agriculture, recently submitted to a Congressional committee a very interesting summary of the work done and some reasons for the work done by that office. Among other things it is shown that the aggregate mileage of the public roads in the United States is approximately 2,300,000, not including Alaska and the island possessions. The total expenditures on these in 1904 approximated \$75,000,000, of which about \$15,000,000, or 20 per cent., was applied to permanent road work. In spite of this great outlay only 5.5 per cent. of the roads are surfaced with stone, gravel, or other hard material. It is evident, therefore, that enormous sums of money are annually wasted in the administration, construction and maintenance of roads, whereas the present outlay should, if properly applied, go far toward providing adequate transportation facilities in the form of improved roads, which are so necessary to our comfort and prosperity.

The United States is far behind Europe in this character of internal improvement, while excelling in most others. The causes may be generally stated as follows: Imperfect State laws; inefficient and improper administration and management of roads; ignorance on the part of local road builders of the principles and methods of road construction; ignorance of the qualities essential in road-building materials and lack of facilities for ascertaining such qualities; lack of sufficient research and experimental work to devise changes or improvements in road materials or existing methods of construction sufficient to meet peculiar conditions, reduce cost, or increase efficiency.

The remedies which should logically come from the National Government may be briefly stated as follows:

1. A general investigation, comparison, and explanation of existing road laws in order to provide legislators with all possible data upon which to consider improvements in existing legislation.

2. Investigation of systems of road administration and management and dissemination of the knowledge thus acquired with a view to the elimination of the worst features and the adoption of the best features in all parts of the country.

3. The introduction of proper methods of construction by familiarizing local road builders with the principles and practice essential to proper road construction and maintenance.

4. Investigation of quantity, location, accessibility, and relative value of road-making materials throughout the country and comparative tests to determine whether or not such materials possess the essential qualities.

5. Experimental and research work on a sufficiently large scale to cope with existing conditions and keep pace with the needs of the country in this direction.

All the remedies above suggested are of such character as would be capable of being realized to the fullest extent only through the National Government. For the States to carry on such work would involve a personnel, equipment, and operating expenses by each State almost as great as would be required of the National Government, with a great amount of duplication in methods and results, and much confusion owing to conflicting conclusions and recommendations. Furthermore, there is ample precedent for investigative and experimental work by the Government and much contemporary example of such governmental activity.

That the work already done by the National Government along the lines indicated in the above-suggested remedies has not produced greater results is due to the fact that the appropriations have been small and the facilities necessarily limited. For several years after the establishment of the office the appropriation remained in the neighborhood of \$10,000 annually. The results achieved by the Office of Public Roads are much more than commensurate with the facilities provided by the appropriations of Congress, and have followed in general the procedure indicated in the remedies above stated.

HOW THE AUTO HELPS SELL LAND IN TEXAS

FORT WORTH, TEXAS, April 1.—Texas lands are in great demand at this time, and it has just been lately that the automobile has entered into the process of selling the lands to such an extent that many people have been buying lands farther out than anticipated, because the automobile has covered the distance from the railroad station to the property in less time than the buyer has been accustomed to riding.

A syndicate of New England men are reported to have bought a large tract of land in the Panhandle, and are selling it off to settlers for farms. The New Englanders, so the story goes, are wealthy men and have not only come down to their lands, but have brought their families and a lot of speedy automobiles. The ground is perfectly level in that section of the State and is ideal for automobiling. When a train load of land seekers arrives, these thrifty New Englanders have their autos at the station, and, with their nicely dressed people, it gives the place a gay and attractive appearance to the tired travelers after their long and wearisome ride through Kansas and Oklahoma. One of these visitors gives the following experience:

"We arrived at the station in the morning, and a gentleman stepped up and asked me if I was looking for a farm. I told him I was. So he invited my wife and myself to get in his auto and he would show us a few of the tracts in that vicinity. We started off smoothly and rapidly, and as we rode along our host pointed out various nice farms they had sold and talked about the various soils, keeping us well interested. Finally we reached a tract of splendid farm land, which just suited us, and

we bargained for it right there. We sailed back to town, reaching there in time for an early dinner, having had a most pleasant morning ride. I bought the land and was well pleased.

"I thought my land was fifteen or sixteen miles out, as it had taken so little time to get there. The day before we had planned to leave I hired a team to ride out and see the place again, taking my wife with me. We started in the morning and never reached my farm until the third day, and it required three days more to return to the railroad station. The automobile had gone so smoothly and rapidly at a fifty-mile an hour gait that I had bought a place seventy miles from town, thinking that it was only sixteen miles out. If that is not a Yankee trick I never heard of one."

Texas is a State of magnificent distances and seventy miles in the Panhandle country is looked upon as a very immaterial proposition. The roads are so good that teams can travel long distances in a day's time, and it is not an uncommon thing for a buggy to cover 100 to 125 miles in a day and automobiles very many miles more.

These thrifty New Englanders have, however, hit upon a brand new scheme and one that is calculated to work the unwary. The automobile ride is so exhilarating in the pure ozone of that section that all sense of distance is completely lost. The victim thinks nothing of the short ride necessary to carry him to his new possessions until he changes gasoline power for horse. Probably in no direction has the automobile made its worth more manifest than in connection with the increase of real estate values.

GEARLESS 'GREAT SIX' SIX-CYLINDER, 75-HORSEPOWER.

SUBSTANTIAL GAIN IN FEBRUARY EXPORTS.

During the month of February past, the value of the automobiles and parts exported increased to the extent of \$110,000 over the same month in the year previous, the figures being \$332,713 and \$443,703. The latter sum represents 213 complete automobiles, making the average value approximately \$1,725, and \$75,394 worth of automobile parts. This substantial jump in the totals for the shortest month of the twelve in 1906 and 1907, amounting as it does to a 33 1-3 per cent. increase, is mainly to be accounted for by the showing of the United Kingdom, which increased from \$49,035 to \$100,065; France, which rose from \$9,495 to \$33,942; Mexico, from \$21,331 to \$96,262, and British North America, from \$34,507 to \$75,206. For the period of eight months ending February in the past three years, the figures are as follows: 1905, \$1,402,775; 1906, \$1,771,313, and 1907, 1,582 automobiles valued at \$2,471,859, and parts, \$401,387. The detailed report is presented herewith:

MEDAL OF HONOR FOR AMERICAN INVENTORS.

At a recent meeting of the Executive Committee of the American Institute of Social Service, it was announced that the *Scientific American* had offered a gold medal to be presented annually by the Institute to the inventor of the best device for safeguarding life and limb. An Advisory Committee of the editors of the chief technical papers was organized to co-operate with the Institute in the work of protecting life and limb. As at present constituted, the Advisory Committee consists of fourteen representatives from the *Scientific American*, *Iron Age*, *American Machinist*, *Railway and Locomotive Engineering*, *Automobile*, *Electrical World*, *Street Railway Journal*, *Dry Goods Economist*, *Electrical Age*, *Railway Gazette* and *Engineering and Mining Journal*.

NO CHANGE OF A. L. A. M. POLICY.

E. H. Cutler, who as chairman of the Executive Committee has been given the active management of the Licensed Association, recently gave out a statement relative to the policy of the association. In part he said:

"There will be no radical changes made under the new regime; the same general policy carried out so ably by Mr. Day will be followed. The purpose of the association to co-operate in every way for the mutual advantage of its members and users of automobiles will be adhered to. To promote confidence in the industry and conserve the interests of those connected with it, through the efforts of its various departments, will be an objective point. The Mechanical Branch, which has done so much for the welfare of the industry, as the cars produced under its standards and specifications attest, will be given every possible assistance by the management of the association; so with the other departments, the traffic, agency, and advertising. The Selden patent, the basic patent which, as everyone knows, covers broadly the manufacture, sale or use of the gas engine for road locomotion, must not be lost sight of in the magnitude of the work being done by the association, and the prosecution of the case which has commanded not only the attention of the entire automobile world, but that of many other industries, will be carried on as rigidly as heretofore. The conduct of a case so voluminous must necessarily be one that would seem slow to those not in close relation to it, whereas its procedure has been steady and persistent. Last summer testimony was taken right through the months of July and August, with no let-up for vacations. It was even taken up to Christmas eve and resumed the day after Christmas, something most unusual in patent litigation."

Mr. Cutler seemed enthusiastic over the early show situation, saying: "From every indication forthcoming shows will prove very interesting; the time seems opportune for the manufacturers to exhibit their products early enough to guarantee early spring deliveries. The licensed dealers have confidence in their factories output and can get their orders in early for special specifications, thus affording the manufacturers an opportunity to produce without working their factories to the limit of their capacity."

ENGINEERING BUILDING TO BE DEDICATED.

Quite an elaborate program extending over two days, Tuesday and Wednesday, April 16 and 17, has been outlined for the dedication of the Engineering Societies Building, which has been erected in New York City by Andrew Carnegie and presented as a gift to the associated engineering societies of New York. The exercises will include a number of addresses.

PEERLESS AND POLAR BEAR RUB NOSES IN DETROIT'S PARK.

GERMAN ALCOHOL EXHIBIT AT JAMESTOWN.

WASHINGTON, D. C., April 2.—Germany will send a large and comprehensive collection of apparatus employed in the production and consumption of denatured alcohol to the Jamestown Exposition, which opens April 26. This fact was conveyed to Dr. Charles E. Monroe, professor of chemistry of George Washington University in this city, who was recently appointed superintendent of the free alcohol exhibit at the coming exposition, in a cablegram from Charles Lesimple, honorary commissioner of the exposition for Germany.

The German exhibit was secured through the co-operation of a number of leading German manufacturers. As is well known, Germany adopted the policy of tax-free denatured alcohol for industrial purposes several years ago, and has led all European countries in its utilization for light, heat and power purposes.

Professor Monroe is advised that the collection of German apparatus will include the small stills, of which seven or eight thousand are now in use among the farmers of Germany; internal combustion engines, which are employed largely throughout Germany, and other classes of machinery employing denatured alcohol. Supplementing the German collection will be numerous American devices for the consumption of alcohol, including automobiles and motor boats. The alcohol exhibit at Jamestown should prove very interesting and instructive.

MORRELL ON A. C. A. ENDURANCE RUN.

Referring to the proposed endurance run to be conducted by the A. C. A. during the coming summer, Chairman Robert Lee Morrell, of the Contest Committee, comments in this vein:

"I cannot speak for the committee, but my idea would be to require the cars to make a hard day's run, perhaps from New York to Albany, half a dozen times. One day they would go to Albany and the next day return to this city and then repeat the operation. That would mean a trip of nearly 150 miles a day. Perhaps it would be advisable to have a control established at Poughkeepsie, but I would suggest that before starting the bonnets and gear boxes of the cars should be sealed, and if a car broke down between the controls it would be out of the contest. A run of this sort would show the real endurance qualities of the motors and it would be a test that would demonstrate the reliability of the car for continuous daily runs beyond question."

Recently Chairman Morrell, following the lead of W. E. D. Stokes, tendered the use of his car to Magistrate Crane for one day each week. Not long ago, when the chauffeur of Mr. Stokes was being tried before the magistrate, the owner of the car offered to supply it weekly for convalescent hospital patients, the assignment to be made by Magistrate Crane.

PITTSBURG SHOW WILL OPEN APRIL 8.

PITTSBURG, April 2.—Great hustling is being done to get the Duquesne Garden ready for the automobile show which opens next Monday night, April 8, and continues until Saturday night, April 13. Never before was the Garden so elaborately decorated for an exhibition of any sort. The setting will be green and white, and the whole hall will blaze with electric lights set in a great variety of figures. From the main entrance one will obtain first a view of long lines of cars from the stripped, polished chassis to the most elaborate limousine car, all the colors known to the coachmaker being observed. On three sides of the regular skating surface of the Garden will be ranged small stands for the display of accessories, leaving the boxes open for the public.

GLIDE MACHINE FOR VANDERBILT RACE.

Announcement has been made by the George J. Scott Motor Company, New York agents for the Glide car, that a special Vanderbilt Cup racer is being built at the factory to represent the firm in the great October race. The machine will be four-cylinder, have shaft drive, and develop about sixty horsepower.

AUTO CABS PROMISED FOR NEW YORK.

The automobile taximeter cab is coming nearer. A few months ago the New York Transportation Company purchased one of the Renault cabs fitted with distance-recording and fare-indicating device used so generally in Europe, and placed it in service at the Café Martin. According to Richard W. Meade, the president of the company, more gasoline machines will be put into commission shortly, all equipped with the taximeter. It is not stated whether the machines will be similar to the one now in service or not, but it is certain that they will have the taximeter, and this after all is the only thing the public is concerned about.

C. W. Kelsey, general manager of the American Cab and Express Company, states that he expects to have gasoline taximeter cabs in use in New York within six months. Walter Christie is also interesting himself in the cab business, and is now busy designing a 20-horsepower, four-cylinder, front-drive chassis for this class of work. All parts will be made at outside factories, only the assembling being done at the Christie works. The first batch will consist of two hundred machines. The taximeter system will, of course, be adopted.

CONDITIONS OF THE 1907 EUROPEAN RACES.

GRAND PRIX: 500 miles in one day. Fuel consumption limited to 6.6 gallons per 62.1 miles. Competitors provide their own fuel of whatever nature they desire. No weight limit or other restrictions. Teams of three from any factory. All work on racers to be done by driver and mechanic.

SPORTING COMMISSION CUP: 800 miles in one day. Fuel consumption, 3.3 gallons per 62.1 miles. All other conditions same as Grand Prix. Will be run at same time as Grand Prix.

ARDENNES CIRCUIT: 375 miles on short circuit, to be finished within eight hours. Cylinder capacity limited to 8 liters. Minimum weight, 2,555 pounds, including racing body and tires, but without tools and spare parts. Gasoline of .69 degrees will be supplied by racing board, no limit on amount.

GERMAN EMPEROR'S CUP: 800 miles. Maximum cylinder capacity, 8 liters. Minimum weight, 2,585 pounds, including racing body and tires, but without gasoline, oil, water, or spare parts. Teams of three from any factory.

TARGA FLORIO: 282 miles over hilly, 94-mile circuit. Four-cylinder engines; bore between 120 and 130 millimeters; weight limit, 2,200 pounds for the minimum bore. Six-cylinder engines; weight allowance, 2,200 pounds for 85 mm. bore; increase of 88 pounds for every additional millimeter bore. Teams of four from any factory.

TWO DAY RUN OF HARRISBURG CLUB.

HARRISBURG, PA., April 1.—Preparations for the two days' run of the Motor Club of Harrisburg are progressing finely, the Exhibition and Runs Committee having drawn the rules for the affair and selected the route. The run will leave Harrisburg on Monday morning, May 6, between the hours of 7 and 7:30 o'clock, and will proceed to Lebanon, Lancaster, Columbia, and thence to York, where the night control will be established. The following morning the cars will leave York and proceed to Hanover, Gettysburg, Chambersburg, Shippensburg, Carlisle and back to Harrisburg. Each day's run will cover about 100 miles. R. H. Johnston, of the New York Motor Club, will bring his car to this city and act as pilot on both days of the run. E. G. Johnson, of the Quaker City Motor Club, will act as referee.

SCOPE OF SOCIETY OF AUTO ENGINEERS.

Though nominally it appears to be affiliated with but one school of engineering, due to the wording of its title, the Society of Automobile Engineers is, on the contrary, one of the broadest in scope and one of the most independent, as it has no connection with any other association. Article 1A of its constitution defines the word automobile as used in the title of the society. This is as follows: "Definition:—The term 'automobile' as used by this society is intended to cover any self-propelled vehicle operating on or under the surface of the earth or water, or in the air."

RALPH OWEN AND THE OLDSMOBILE WINNER OF SAN FRANCISCO-LOS ANGELES RACE.

OLDSMOBILE TRIUMPHS IN \$6,000 RACE.

LOS ANGELES, March 30.—Owing to the execrable state of the roads the much-talked-of contest between the Oldsmobile and Pope-Hartford cars that was to have taken place on the 14th was postponed to the 28th; and although the roads were not in much better condition than previously, the contestants decided to start. The race is the result of rivalry of long standing between E. P. Brinegar, of the Pioneer Auto Company, San Francisco, and H. D. Ryus, of the Pope-Hartford agency in Los Angeles. Mr. Ryus piloted the Pope-Hartford and Ralph Owen, of "Mudlark" fame, the Oldsmobile. The latter won the toss and chose the later start, so that the Pope-Hartford left at 5 A. M. and the Oldsmobile half an hour later.

H. D. RYUS AND POPE-HARTFORD FORDING A STREAM EN ROUTE.

Owen was heard from first at Bakersfield, announcing that he had passed Ryus about fifty miles out. The latter was not heard from again, and it turned out subsequently that the car had hurdled an embankment and broken its rear axle. For the first half of the distance of 500 miles, the roads were in an almost impassable state, and on two different occasions it was necessary to extricate the Oldsmobile from the mud with the aid of teams, the rear wheels having almost disappeared.

A MATCH RUN BETWEEN TWO FLORIDA CITIES.

By WANDERER.

JACKSONVILLE, FLA., April 1.—Ralph Owen's New York-Ormond tour has aroused in Florida drivers an ambition to make the run between Jacksonville and St. Augustine quite frequently, although the highway is of the common sandy variety and about as hard a piece of road to tackle as one can find.

Mr. Hutto, the Cadillac agent in Jacksonville, recently drove his single-cylinder the forty miles between the two cities in 2 hours and 40 minutes. The time was not generally credited, but that Mr. Hutto made it was proven beyond a doubt by his performance in a match run of the other day. While the Ford made the distance in 2 hours 17 minutes, Mr. Hutto was only 13 minutes behind him.

L. C. Oliver, the Ford agent, recently came out with an advertisement stating that he would match the six-cylinder Ford against any car in Jacksonville for any kind of test. Mr. Hutto took up the challenge. He is a native product, and the majority of the people believed that the Florida "cracker," through his knowledge of the country, would defeat the Ford. The betting, of which there was considerable, placed the little Cadillac in favor, all conditions of the match giving the Cadillac the best of it; for, if he won, it would mean a great deal to the agent, and if he lost there would be no disgrace attached to it, as it was a 6 to 1 proposition in favor of the Ford. Many believed that the Ford would get in trouble through its speed, and that the driver would either break some part of the machine through striking a tree or hitting the uneven places.

The writer, with Manager Morris of the Windsor Hotel, went out in a Maxwell runabout to South Jacksonville and was stationed at the end of the hard road which terminates about two miles south of where the sand road begins. The rivals started at 9 o'clock sharp and we soon heard the roar of the Ford, which was coming along at about fifty miles an hour. The machine had been stripped of its big tonneau, and an extra tank of water had been placed in the rear, feeding to the water cooler. This was a wise precaution, as it is doubtful if any water could have been found on the road in case the original supply should boil out. The Ford driver slowed down to about forty miles when he struck the deep sand, but that was too fast, as the machine bounded from side to side, and barely escaped hitting a two-foot water oak. The "Commodore" and driver were ready to jump, and the spectators ran back into the woods, expecting a disaster. On regaining his steering control, by which time he had slowed his engine down, the driver straightened out the machine, struck the center of the road, and the last seen of him he was making good progress, with the sand falling from the chain wheels.

About two minutes later Hutto, with his steady-going Cadillac, hove in sight. He did not follow the Ford, but took a road to the left, which he had tried the day before.

At half distance the Ford passed 1½ minutes ahead of the Cadillac. The spectators there stated that the Cadillac was cutting off the corners and not keeping to the road where it was bad. Later on the Ford broke a spring, and Hutto passed his rival, who, however, soon made his repair, caught, and passed the little machine, reaching St. Augustine 13 minutes ahead.

The race aroused considerable enthusiasm, and now the cry is for hard surface roads, which I believe will come in the very near future. The Cadillac agent desires another trial, but wants the Ford to be equipped just as it is sold from the shop, without extra water tank, and with the tonneau on.

HENRY FORD ON VANADIUM'S WORTH.

"Vibration—fatigue—crystallization; how many persons glibly use these terms and how few really appreciate their tragic import," said Henry Ford, in discussing the reasons for the application of the rare element, Vanadium, in the making of special steels for motor car construction. "Yes, tragic is the word. Few people realize how many accidents, otherwise unaccountable for, are due to the ravages of vibration and the consequent fatigue of the metal—a popular term for which is crystallization. An axle, a spring, crankshaft, frame, or any other part that has gone through months, possibly years, of rigorous work and withstood many a shock without showing any weakness, snaps like glass some fine day when there is no apparent cause for it. To the average engineer versed in the problems of other branches of mechanics this is a mystery, but the automobile engineer has long since learned the reason, and his chief concern has been to find a metal that would resist the ravages of this insidious enemy of the motor car. The quality of resisting repeated shocks, alternating stresses and vibratory action is termed 'dynamic.' And a steel which possessed the necessary dynamic properties to withstand fatigue to almost its ultimate breaking point and yet finally yield under the severest shock or stress without fracturing was the goal of our metallurgists. To obtain this result we must increase the dynamic properties without sacrificing the static qualities—must double the elastic limit and yet maintain, or increase also, the tensile strength of the metal.

"There was but one element known to metallurgy that would accomplish this end. That was Vanadium, a mineral so rare, its interest to steel specialists up to this time has been academic only. Happy circumstance has now placed it within our reach. A large deposit of the hitherto commercially unobtainable mineral has been opened up in South America, and Vanadium steel can now be made—in fact, we are making it—at about the same cost as the best grades of nickel-steel, to which latter it is incomparably superior in the properties above indicated."

AUTO TRADE AT THE HUB.

BOSTON, April 1.—Since the close of the automobile show there has been much activity among local dealers, taking care of the business that was worked up during show week. The Dodge Motor Vehicle Company, representatives of the Pope cars, the exhibit of which was the largest made by a single firm at the show, has this week delivered all the nineteen cars that were shown to their owners.

Since the show a number of local firms have moved into new quarters. Among these is the A. E. Morrison Company, agents for the Stearns and Oldsmobile, which has taken possession of its new show and sales rooms on Massachusetts avenue, near Commonwealth avenue, and now has one of the finest show rooms in New England. The quarters which the A. E. Morrison Company left on Massachusetts avenue have been occupied by the Matheson Company of Boston, of which Roy A. Faye is manager. The show rooms of the Henshaw Motor Car Company, agents for the Haynes and Columbus electrics, which are in the same building as those of the A. E. Morrison Company, are not quite completed, but will be ready for occupancy in a few days.

In the past few days, also, a new automobile district has been opened up on Huntington avenue. In the garage of the Back Bay Automobile Company, just above Mechanics' Building, the Buck & Price Company, agents for the Rainier, and the H. C. Stratton Company, agents for the American Mercedes, Car De Luxe and Kissel Car, are now located. The new agency of the Darracq is also on Huntington avenue, and with the opening of the Copley Square garage on Irvington street, near Huntington avenue, it is expected that several other firms will move into this section. There is a marked tendency to get away from the older automobile section on Columbus avenue, and as fast as buildings can be erected in the Boylston street and Massachusetts avenue section they are being snapped up for automobile stores.

THE GLOBE-GIRDLER PUNCTURED A BOOST.

This story is by Robert W. Spangler, a Chicago auto scribe: Charles J. Glidden, the globe-girdling autoist, was last week in Chicago, and one day was a guest of C. A. Coey at the Auditorium Annex for luncheon. Mr. Coey resides at the Annex, and consequently is well known to the employees. One of these is Prince Smile Arajh, of India, whose white suit and dark complexion distinguish him from the other head waiters. Seeing Mr. Coey dining with a stranger, and thinking he was perhaps a prospective customer for a Thomas Flyer, the Prince approached the table, apologized for intruding, but said he wanted to tell Mr. Coey that the half-dozen Thomas cars which he had shipped to India were giving perfect satisfaction in the royal household. To strengthen his statement he produced a post-card photograph showing, so he said, a number of the royal family in one of the Thomas cars. This card he exhibited very impressively to Mr. Glidden, who smiled faintly as he looked at it, but said nothing. The Prince then made a few more remarks in praise of the Thomas cars, and left the vicinity of the table. Turning to Mr. Coey, Mr. Glidden said:

"Your Indian friend is certainly a good advertising medium for you, but he overreached himself that time. The picture he showed us was one I took of my car in India last year."

TRADE IS LIVELY IN PHILADELPHIA.

PHILADELPHIA, April 1.—At an informal dinner at the Hotel Majestic last week, at which President Thomas, of the E. R. Thomas Motor Car Company, of Buffalo, was the host, the announcement was made that the Thomas Flyer and the Thomas Forty would be handled in Philadelphia hereafter by the United Motor Car Company, of which H. A. Dawson is president and A. H. Dorsey vice-president and general manager. The Thomas cars were formerly represented here by Martin & Hart at 215-217 North Broad street, where the new concern will continue the Thomas headquarters.

The largest automobile accessories establishment in this city—the Auto Equipment Company—opened up at 144-146 North Broad street last week. Morris Penrose, former manager of the local branch of the Fisk Rubber Company, is at the head of the new concern.

The new garage of the Foss-Hughes Company, now rapidly approaching completion at 221-223 North Watts street, will be run on the club plan, all its facilities being placed at the disposal of Pierce-Arrow, Cadillac, and Baker electric owners for limited periods free of charge.

To-day marked the opening of the first public auto express company in this city. Its official title is "The Auto Express and Trucking Company," and two vehicles were started this morning. The two vehicles put to work to-day were three-ton and two-ton trucks, built by the Reliance Motor Car Company. It is announced that the service charges will be from 25 to 50 per cent. lower than those at present in force, and that the business is bound to increase.

IMPORTERS NAME COMMITTEE TO CONFER.

At the meeting of the Importers' Automobile Salon, which was held during the latter part of last week, the consensus of opinion was general that with the Licensed Show occurring in the early part of November a showing of imported cars at a later date would be imperative. A committee consisting of E. R. Hollander and C. R. Mabley was appointed to take up the matter with the Association of Licensed Automobile Manufacturers, whose contract with the Garden precludes the holding of automobile shows in the latter not sanctioned by that body. Officers for the ensuing year were elected as follows: President, J. S. Josephs (Rochet-Schneider); vice-president, E. R. Hollander (Fiat); treasurer, C. F. Wyckoff (C. G. V.); secretary, S. B. Bowman (Clement-Bayard); directors, the officers named and C. R. Mabley (Isotta-Fraschini). An aggressive policy for the year was decided upon.

ACTIVITIES AMONG THE GARAGES.

Large Garage Under Construction at Auburn, N. Y.

Work of construction has been begun on the new garage at Auburn, N. Y., which will be occupied and operated by the Auburn Automobile Company, and which, when completed, it is said, will be the largest garage between Albany and Rochester, and one of the largest in the State outside of New York City. The building, which is to be of brick and concrete, will be entirely fireproof. It will have a frontage of 180 feet and a depth of 60 feet. It will be one story in height, and will occupy the plot of ground extending from the corner of Green and Water streets west, nearly to Hulbert street. The machine shop will be at the west end of the building, 30 x 60 feet. At the east end will be the offices, and a waiting room for ladies, also a reading room for chauffeurs off duty. The store room, or garage proper, will occupy the remaining space, and will be 130 x 60 feet. Here fifty cars can be accommodated at once, and there will be a row of stalls wherein cars may be locked by their owners to insure privacy. An important feature of the proposed building is that the roof will be supported by arched girders, so that there will be no posts in the building to interfere with the movements of the cars. The building will be ready for occupancy about the middle of May.

Centrally Located Garage for Minneapolis.

An edition de luxe of the modern automobile garage is to be built one block from the Plaza Hotel, Minneapolis, Minn., which is headquarters of the Minneapolis Automobile Club, by Joseph J. Barclay, of the Barclay Auto Company. It will stand at the junction of Huron street and Hennepin avenue, on land belonging to L. S. Gillette. The garage will be built at once, and will be of fireproof construction, with an exterior of white sand lime brick. Steel will be used to support the roof and leave the interior clear. The basement will be full size, with two stories above. The building will cost \$30,000. The ground dimensions are 90 feet on Hennepin avenue and 115 on Huron street. The first floor of the new Barclay garage will be divided into two sections. The upper 35 feet will be used for cars and the 51 feet lying on Huron street for the main garage. The entrance will be from Hennepin avenue.

Modern Garage Under Construction at Geneva, N. Y.

The work of demolition of the old Maynard house at 143 and 145 Castle street, Geneva, N. Y., has been commenced to make room for the Geneva Automobile Company's garage. The building will be two story brick, connected with the present building in the rear, making the new home of the company 132 feet long and 40 feet wide. The estimated cost of the improvements will be about \$7,000. A double track will make it possible for a car to enter the building from either Castle or Main streets and pass out again without turning round. Near the main entrance will be a fifteen-foot turntable. The second floor of the building will be fitted as a clubroom with toilet and wash room adjoining.

A \$200,000 Garage for the City of Pittsburg.

The Standard Automobile Company, of Pittsburg, Pa., will soon break ground in Aiken avenue for a six-story fireproof garage, 100 x 150 feet. The structure will probably be of the new reinforced concrete type, and will cost with the fixtures and machinery \$200,000. President W. N. Murray expects that the big garage will be ready for use in the fall. Mr. Murray was one of the pioneer automobile dealers in Pittsburg, having entered the field in 1900 as a partner in the firm of Seeley & Murray. The Standard now occupies a series of buildings at Baum and Beatty streets, and for two years its business has been far in excess of its convenient capacity for handling it.

Washington's New Garage Will Accommodate 40 Cars.

The new automobile garage of the Capitol Hill Garage Company, at 615 B street, southeast, Washington, D. C., is now near-

ing completion. The new building, which will accommodate forty vehicles and be modern in every respect, is the only one within a mile of the Capitol. J. J. Flynn has purchased the interest of H. T. Acre and is now sole proprietor of the company.

GARAGE DOES THE COUNTRY OVER.

Philadelphia.—Charles G. Henderson is building a one-story garage, 474 by 130 feet, at Philadelphia, on Fifty-first street, north of Westmoreland street. The cost will be \$8,000.

Zanesville, O.—F. A. Clark, proprietor of the Buckeye garage, has arranged for the erection of a handsome one-story brick and concrete garage on Eighth street, Zanesville, O.

San Diego, Cal.—Work has been begun on a new automobile garage for Horace B. Day at 1144 First street, San Diego, Cal. The total cost of the new structure will be about \$6,000.

Buffalo, N. Y. Volney P. Kinne has filed plans in the Bureau of Building which provide for the construction of a two-story brick garage at Nos. 1114 to 1118 Main street. The garage will cost \$14,000.

Thomasville, Ga.—A good-sized garage is to be established in this place by William Miller, which will be in readiness within a month. Thomasville is getting the auto fever in a pronounced manner, and a modern garage will be welcomed.

Detroit, Mich.—Robert L. Fee will build a garage to be devoted exclusively to the use of electric automobiles on the south side of Jefferson avenue, just east of St. Antoine street. The garage will be operated under the name of the Fee-Vincent Company.

Evansville, Ind.—After remodeling, the Dyer block at 320-322 Upper Fourth street, Evansville, Ind., has been occupied by the three Fellwock Brothers as an automobile salesroom and garage. The title of the new business will be the Fellwock Automobile and Manufacturing Company.

Columbus, O.—A new garage will shortly be opened in this city by John Field, manager of the Columbus clearing house, and A. C. Kyle, of the Broad-Oak Company. The garage, which will have all modern appliances, including an electric charging plant, will be on the ground floor of the Broad-Oak skating rink.

Waterloo, Ia.—The Summit Carriage Mobile Company has just opened a garage and factory at 512 Lafayette street, Waterloo, Ia. E. D. Cadwell is in charge of the plant. W. W. Eggers has also opened an up-to-date garage in this city, and contracted with the Bartholomew Company, of Peoria, Ill., for twenty of its large Glide touring cars.

Minneapolis, Minn.—Evans Motor Car Company, now located at 719 First avenue, South Minneapolis, Minn., is building a new garage, 50 by 125 feet, on Hennepin avenue, between Fifteenth and Sixteenth streets, which they will occupy when completed. Agencies for Mitchell, Wayne and Jewell cars have been secured for 1907.

Avon, N. J.—Located about midway between the two popular summer resorts, Belmar and Asbury Park, N. J., the garage just completed and to be managed by John Thompson, at Avon-by-the-Sea, should be a convenience to summer tourists. The new building is located at the corner of Main street and Sylvania avenue, is 50 by 100 feet, and will be fitted with a charging plant for electrics.

Pittsburg, Pa.—H. H. Marks, of New York, has purchased from H. M. Aronson the five-story brick building in Henry street, Oakland, formerly occupied by the Oakland Livery Company, for \$90,000. The building has over 40,000 square feet of floor space. The purchase was made with a view to fitting up the big structure for the largest automobile garage in this State. It is reported that it will be the headquarters for the Rainier car, and that a big storage plant will be arranged also. A. L. Richmond, Jr., owner of the Hotel Lincoln, is said to be interested in the venture.

I, BUILDER OF MANY RACING CARS.

ostentatiously away at the plant of the E. R. Company, at Buffalo, is a man who has superintended the construction of more prize and cup winning motor cars in the world to-day. The man is Michael Amide, although the greater part of his work lies with the regular production of stock cars for the Thomas company, he is at present engaged in superintending the work of remodeling and tuning up the three 115-horsepower racing cars that will be entered in the Vanderbilt Cup race this fall.

DE LONGERON.

His racing car experience commenced in 1895, when he constructed the cars that won the great Paris-Berlin, Paris-Bordeaux, and Paris-Toulouse races, and the Tour de France. In addition to these he has since constructed the cars which in 1904 and 1905 won the French elimination trial for the Ardennes cup, the French elimination trial for the Auvergne cup, the French cup itself, and in both those years the French trials for the Gordon-Bennett cup race and the Gordon-Bennett proper. That list is in addition to a number held in Europe.

Last year he constructed the three Thomas cars, one of which led the American team in the Vanderbilt Cup race and now has the work of fitting those machines, "green" at that time, for the two events in which they will participate on Long Island, the American elimination trial and the cup race proper.

NEWS FROM THE CITY OF THE MAUMEE.

TOLEDO, O., April 1.—Toledo automobile dealers consider their first attempt at holding an automobile show to have been so much of a success that they have already announced that another show will be held next year on greatly enlarged and much more elaborate plans. In addition to the display of cars, marine engines, oils and accessories, airship *Toledo No. 1*, was on exhibition, while Roy Knabenshue, Toledo's noted aeronaut, made explanations. A band of thirty pieces was present throughout the show and an opening address was made by Mayor Brand Whitlock. Noteworthy was the interest taken in the show by country people, who in many instances traveled miles to see the show, and whose interest marks an advance for the industry.

Monroe, Mich., a small town some twenty miles north of Toledo, is agog over the visit of a number of strangers, who spent some time there during the past week looking for available sites for the announced purpose of erecting an automobile factory. While mention was not made as to what concern was represented, enough was stated to lead to the belief that they represented some operating plant which is looking for a site away from the larger cities, where labor unions are likely to cause trouble.

The Toledo Storage Battery Company is placing a new battery for automobile owners on the market. Its first public appearance was at the Toledo automobile show last week.

The new city ordinance requiring automobile owners to display numbers in a conspicuous place on their machines goes into effect April 1, and there is now a grand rush on the part of owners to comply with the new law, which is the final outgrowth of a fight covering several years.

GROWTH OF A MODERN AUTOMOBILE PLANT.

Starting originally with an ordinary factory building of small dimensions in the east end of Cleveland, the Winton Motor Carriage Company has, in the course of a comparatively small number of years, even as such things go in the automobile industry, developed one of the largest and most complete plants for the manufacture of automobiles to be found in this country, or even in the world. It was not long before the original facilities mentioned, consisting of the former plant occupied by the Brush Electric Company, were outgrown, so that as far back as 1902 the beginnings of the present plant on the Berea Road in the outskirts of the Forest City were undertaken. With an eye to the future development that followed so quickly, a large tract of land was purchased on the line of the Lake Shore and Michigan Southern Railway. The first buildings erected were the powerhouse, foundry, machine and paint departments and the shipping room. Though the latter were occupied for the first time in the fall of 1902, the following year saw the erection of new buildings to house the assembling and repair departments and the woodworking shop. At that time the buildings did not occupy the land to the exclusion of everything else, and a half or three-quarter mile board track was made around them for the testing of cars. The Winton restaurant constitutes a department that was added and housed in 1905. Last year the machine and paint shops were enlarged by a 25-foot addition on the side fronting the Berea road, as well as by a second story on both and a third story over the east end of the machine shop to accommodate the draughting department. Some idea of the extent of the plant as it stands to-day may be had from the illustration of the factory and its surroundings printed below.

BIRD'S EYE VIEW OF THE PRESENT EXTENSIVE PLANT OF THE WINTON MOTOR CARRIAGE COMPANY, CLEVELAND, O.

BRIEF ITEMS OF NEWS AND TRADE MISCELLANY

Plans are under way for a new building on Michigan avenue for the Chicago store of the Pierce Engine Company, of Racine, Wis. It will be located south of Fourteenth street.

Announcement is made by the Larchmont Automobile Company, of Larchmont, N. Y., of the opening of a first-class garage on the Post road between Larchmont and Beach avenues.

The York Motor Car Company, of York, Pa., is experiencing a very busy season. The company is now turning out Pullman cars at the rate of eight per week, and one-half of the season's output will be delivered by April 1.

The Maxwell alcohol economy run to be held from Trenton to Atlantic City has been postponed until April 5, as it was found impossible to put the car selected for the test in the best condition for the run before that time.

The Carter Motor Car Corporation announces that a selection is about to be made of a tract of land near Washington, D. C., as a site for their new factory. The location is an ideal one, having excellent shipping facilities and being easily accessible by electric cars.

Arrangements have been perfected between the directors of the Geneva, N. Y., Chamber of Commerce and David Reid, president of the Motor and Manufacturing Works Company, of Ithaca, to remove the industry to Geneva. The new company will have a capital of \$40,000.

"The automobile buying public will soon learn," says Charles B. Shanks of the Winton company, "that no quantity of special steels in an automobile can offset ignorance of the 'know how.' It is always safest to buy cars made by men of the broadest experience, for they are the only ones who know how, when, why and where to use and not to use special steel mixtures."

In New York State the registration of automobiles has reached the great figure of 37,850. Allowing for registered cars not in use and the sales of cars a second time, it is estimated that more than 30,000 automobiles are employed in this State. Of this number it is figured that 15,000 are owned in New York City. In registrations New Jersey stands second to New York, with a total of 26,650 to the end of March. Massachusetts has a total of 18,170 and Pennsylvania 3,775.

"Procrastination," says a well-known Columbia dealer, "is one of the worst features of the average autoist. He thinks that a car should perform consistently day after day without so much as a casual looking over. A little oil here and there, taking up the chain slack, maintaining a constant oil level, care in engaging the clutch and shifting gears, keeping contacts bright and clean—in fact, any of these numerous little operations which could be performed in periodical inspections would easily keep the car up to the highest standard of efficiency."

Asked in relation to the annual Orphans' Day outing, inaugurated by the New York Motor Club, R. M. Owen of the Owen company, distributors for the Reo and Premier, says that he is in

hearty accord with the plan of taking a great number of parentless children to Coney Island for a day's pleasure trip. Mr. Owen further says: "We will be pleased to furnish Reo and Premier touring cars. Movements of this nature should receive the hearty support of dealers, for they tend to cultivate a friendly public attitude towards motorists as a whole, the benefits of which to the trade cannot be overestimated."

One of the most popular shock absorbers and jolt eliminators now in use is that made by the Hotchkiss Manufacturing Company of Chicago. The Hotchkiss device sets on the springs and the principle of operation is a piston working in a circular cylinder, alternately forcing glycerine through a large check valve and a small needle valve. On the downward compression motion the glycerine passes through the check valve without resistance, and returns to the cylinder, allowing free play to the springs. The slightest pressure on the recoil closes the check valve, the piston reverses, and forces the glycerine through the needle valve, which is regulated from the outside to the exact pressure required to check the recoil and bring the car back to its normal position, slowly, without jar or jolt, a feature upon which the manufacturer of the Hotchkiss lays much stress.

NEW AGENCIES ESTABLISHED.

George L. Lyon, State agent for the Reo automobile, has made a contract with Messrs. Ham & Ross to handle the Reo in Charlotte, N. C.

The Orlando-Kessler Auto Company is a new concern located at 36 West Capital street, Columbus, O. Lozier and Autocar are represented.

A recent addition to the Boston auto trade is the Atlas runabout, made in Springfield and sold in Boston by J. W. Crowell at 92 Massachusetts avenue.

The Franco-American Auto and Supply Co., of Chicago, announces the appointment of the following agents as distributors of Michelin tires and the territory covered by each: Curtin & Williams Co., Columbus, O.; Coughlin & Davis, Cincinnati, O.; H. B. Groves Company, Sioux City, Ia.; Norris Automobile Company, Saginaw, Mich.; Kirk Bros.' Motor Car Company, Toledo, O.; Fawkes Automobile Company, St. Paul and Minneapolis, Minn.; W. C. Anderson, Cleveland, O., and radius of fifty miles; Western Auto Supply Company, Cedar Rapids, and Eastern Iowa.

PERSONAL TRADE MENTION.

W. R. Walton has been appointed Northwestern representative of the Firestone Tire and Rubber Company, traveling out of Chicago. Mr. Walton was formerly Wisconsin representative of the Fisk Rubber Company.

A. W. Church, secretary of Wyckoff, Church & Partridge, is expected to arrive in New York shortly, having recovered from the accident that he met with some time ago while returning in his carriage from the theater.

RECENT TRADE PUBLICATIONS.

The Victor hand-forged automobile is a simple, low priced machine for which many claims are made in the booklet just published by its manufacturers, the Victor Automobile Manufacturing Company, 171 Carroll street, St. Louis, Mo.

The feature of the smart little catalogue on Albany grease, made by Adam Cook's Sons, 313 West street, New York, is that it gives general directions on how and how often to lubricate such important parts as axle bearings, gear case, steering gear, chains, etc.

Catalogue twenty-two, from the Manhattan Electrical Supply Company, Park place and Murray street, New York, contains something electrical for everybody. The entire field of electrical appliances is covered and of course the automobilist's requirements are not overlooked. Each article is described, illustrated and priced.

A special circular has been issued by the Motor and Manufacturing Works Company, Ithaca, N. Y., on their well-known types of ejector mufflers. The booklet contains a complete price list, a description of the features of this type of muffler, and full particulars of the various types manufactured for automobiles, marine and stationary engines.

Cold drawn seamless steel work as produced by the Nortmann-Duffke Foundry Company, Twenty-sixth and Layton avenues, Milwaukee, Wis., is described in the company's new catalogue. The work includes seamless steel reservoirs, carbonate shells, cylinder tanks, crucible steel castings, gray iron castings, etc. They are all fully dealt with in the booklet.

The Great Smith catalogue is an elegant production, dealing worthily with the Great Smith, built by the Smith Auto Company, of Topeka, Kan. The description is complete, the illustrations are excellent, and altogether the catalogue is one which presents the Smith in a very interesting manner. The catalogue can be obtained from headquarters or from the New York agency, 1855 Broadway.

"Betty" has come to town. Her arrival is not likely to pass unnoticed, for "Betty" is the Goodrich girl—the Goodrich girl divine. She is a handsome girl, too. She has no designs, but simply asks a place. If she has not called upon you, a word to the B. F. Goodrich Company at Akron, O., will bring her. To the small number out of the pale of Goodrich acquaintanceship she will cost 75 cents, postpaid, to applicants by mail.

AN EFFECTIVE SIGNAL GONG.

A signal which sends an alarm far ahead of the automobile is always a necessary fitting. The Watres auto gong, which has been marketed by the Watres Manufacturing Company of 1139 Broadway, is a powerful three-tone chime gong operated by the exhaust stored in a separate tank. By this system the signal can be sounded at all times, when the car is running down hill with the engine dead, or when the auto is at a standstill. The device is simple to attach, requires no special machine work and sells at a moderate price.

INFORMATION FOR AUTO USERS.

A Novelty in Tool Boxes.—Some time since, a Rambler dealer, on a visit to the factory at Kenosha, was shown the drafting room. He was interested in the cases of drawing instruments, with each article in a compartment adapted thereto, and finally expressed himself thus: "Say, why can't we have cases like

RAMBLER TOOL BOX.

that so that our tool boxes won't sound like a junk shop in a cyclone and a man may be able to get what he wants when he wants it without digging for it." The outgrowth of the suggestion is a double-top tool box as shown in the accompanying illustration. The entire cover is aluminum with the lower section designed to hold four wrenches, two spark plugs and a socket wrench. A rubber lining in the cover prevents rattling and displacement of the tools. The latch is so constructed that the entire cover may be raised, giving access to the body of the box without releasing the latch holding the two portions of the cover together. It is now a part of the regular equipment of all Rambler cars.

The "Pater-Noster" Shock Absorber.—Experience and patient investigation extending over a number of years has demonstrated that the solution of the suspension problem appears to point in the di-

PATER-NOSTER SHOCK ABSORBER.

rection of auxiliary shock dampening devices rather than more or different kinds or sizes of springs, as despite the great improvements in the latter during the period in question, there is no doubt in the mind of any designer at the present day of the necessity of a shock absorber

on the car. In view of this, a description of the Pater-Noster, which is the result of three years' study on the part of the European house of Herz & Company, and is manufactured by the same concern at their works at 203-205 Lafayette street, New York City, will be found of interest. Patents have been taken out in a number of different countries, and the Pater-Noster has been widely adopted on the Continent before its advent on this side of the Atlantic. In its design, both the upward and the downward movement of the car are taken into consideration, so that each movement may be checked separately.

It consists of two brake bands side by side, working on two separate drums. One of these drums is cast integral with a sleeve sliding over a central bronze arbor extending out of the bronze casing which encloses the whole mechanism. The other brake drum is connected with the central arbor only through the medium of a roller clutch. The entire mechanism is encased in a bronze housing which is filled with glycerine. The roller clutch allows the free downward movement of the spring and holds in but one direction, that of the recoil. The downward jar is taken care of by the second brake band, this being a particular feature of the Pater-Noster already made mention of. In the lever connecting the device with axle is inserted a device termed the "auxiliator," permitting short movements of the spring.

Brown Separable Lock Spark Plug.—Simplicity and ease of cleaning are two prime requisites of a good spark plug, and the inventor of the Brown separable lock plug has combined them in the design of his device, which is now being made and marketed by the Progressive Manufacturing Company, Torrington, Conn. As will be plain from the illustration of this

BROWN SEPARABLE LOCK PLUG.

plug showing it apart, the porcelain can be removed with half a turn without disturbing any other part of the plug, and without the aid of a wrench. Nor need the terminals be disconnected, as the porcelain does not turn in releasing. In addition to these advantages, the construction of the plug is designed to prevent carbon reaching the insulation. These plugs have been given a thorough

trial in actual use extending over a lengthy period and have been found to give excellent service. Beside this plug on which patents have been applied for, the same concern also manufactures the Brown regular or standard spark plug, shown in the second illustration.

Kane Self Starting Device.—The fact that the gasoline motor has to be cranked to get it under way has always been considered one of the greatest drawbacks of the automobile. Devices innumerable have been invented to overcome this fault, and more and more attention is being paid to the question of evolving a device that will be at once simple, practical and inexpensive, not to mention that chief requirement of all, re-

KANE SELF-STARTER FOR MOTORS.

liable. The Kane Starting Device Company, 762 Junction avenue, Detroit, Mich., have just brought out the mechanism shown in the accompanying illustration, which is small and is attached where the starting crank connects with the motor shaft. It is placed under cover and is operated from the driver's seat. It consists of two roller ratchets and a wedge chair so arranged that the slightest backward movement of the motor releases the grip on the shaft entirely. The main or working ratchet is released by wedges which act only on the reverse action of the motor. On the secondary ratchet there are 45-degree grooves, engaging with internally cut grooves of the same pitch in the outer member surrounding the secondary ratchet.

The outer member cannot revolve, being held in position by pins, but reverse action of the motor and the working of the secondary ratchet makes a positive movement of the outer member toward the main ratchet thereby forcing the wedges behind the rollers and causing a positive release of the shaft. When the reverse action of the motor ceases, the wedge chair is returned to its normal position by springs operating between the main ratchet and wedge chair which also force the outer member of the secondary ratchet to its place.

Lubricating Oils for Special Purposes.—The Underhay Oil Company, Boston, Mass., are sending out an attractive folder in colors showing on the outside a Continental soldier aiming his old flint-lock intently at something in the dis-

tance. It is captioned "Our Aim," and the makers go on to state that this is to produce a line of lubricating oils of superior and uniform quality, especially adapted for the purpose to which they are to be applied, and on that account the most economical in service. Some of their brands are "Premium Valve Cylinder," "216 D. Cylinder," "Monarch Cylinder," "Electric Cutting" and a number of others.

The Auto Folding Lunch Box.—Nothing is quite so conducive to good appetite as a spin over country roads in fine weather, and when it is a question of

A HANDY LUNCH BOX FOR AUTOISTS.

catering to the internal wants of the passengers of a touring car no little space is required to accommodate a sufficient quantity of edibles. To provide a handy means of carrying them, the Atlas Manufacturing Company, Hampton, N. H., has brought out a line of auto folding lunch boxes. They are made in various sizes, operating on the same general principle as is usually employed in collapsible boxes. A high grade of leather board is employed and well braced, the sections being bound together with leather hinges, making them light and strong.

Convenient Acetylene System.—Up to the present, acetylene gas has always been generated as used, or carried in special tanks under pressure on the automobile, but the Eco Manufacturing Company, 53 State street, Boston, Mass., manufactures a device that automatically makes and stores the gas in a tank ready for use—a method that possesses many advantages. The flow of water is con-

AUTOMATIC ACETYLENE GAS SYSTEM.

trolled by a diaphragm regulator operated by the pressure of the gas, but as a further precaution the generator is provided with bronze safety valve set to blow off at a low pressure. The generator proper consists of an upper and lower tube, the latter divided to form two carbide chambers; threaded caps close the ends of these chambers, making them gas tight. Each chamber accommodates

a basket for the carbide. The upper tube is also divided into two parts, consisting of a water tank and a storage tank. The former is provided with a gas-tight filling vent and an outlet level with the bottom of the tank, to which is attached the automatic water valve. From the latter, two pipes lead to the carbide chambers, with shut-off needle valves independent of the automatic valve, to stop the flow of water when the generator is not to be used for some time or when recharging.

The storage tank has a safety valve, gas outlet, pressure gauge connection and reducing valve in piping leading to the lamps. The generator is so designed that no water can possibly reach the carbide except through the automatic regulating valve, so that the vibration of a car or the rolling of a boat does not affect it. The best of Tobin and phosphor bronze is used throughout in its construction, making the generator an ideal device for touring or yachting, as several weeks' supply of gas may be carried in the form of carbide in a small space.

Compression and Valve Tester.—Under the title of the "Compressometer," Henry W. Brown, Syracuse, N. Y., is placing on the market a device that will be found very convenient when the location of a fault in the compression of a cylinder, whether through defective piston rings, or from poorly seated valves, is in ques-

THE BROWN COMPRESSOMETER.

tion. It consists of a frictionless 100-pound gauge, the indicating point of which remains at the highest point reached until returned to zero by hand. A unique ground swivel joint connects the cylinder under test with the instrument. This joint, which permits of placing the gauge face at any angle, is independent of the instrument itself and screws into the cylinder like an ordinary spark plug.

A Radically Novel Speedometer.—The Casgrain speedometer has the decided advantage that the dial movement is practically one-half inch for each mile instead of six miles in every half inch of dial, as is sometimes the case. In other words, the progressive miles on the dial, from 0 to 65, extend over a distance of twenty-eight inches. This not only gives figures of good size and for every mile, but it means that if the figures are out of adjustment 1-4 inch the instrument would not be more than 1-2 mile away from the accurate reading, while on a 5-inch indicator reading the same 1-4 inch out of adjustment would mean nearly six times that inaccuracy, or about three miles. This ought to give thought to those looking for accuracy and a dial easily read because of its slow movement.

To give this long reading, the figures run around a barrel in a helical line of a fraction more than four turns. On the inside of this barrel are inwardly projecting vanes and the barrel itself moves back and forth on a center worm corresponding in pitch to the helix of mile figures. Outside this barrel is the enclosing case with an opening through

FRONT VIEW OF CASGRAIN SPEEDOMETER.

which the reading becomes visible. The usual flexible shaft is used to operate the instrument, but this shaft only moves a second shaft in the instrument itself, there being no mechanical connection between the indicator and this mechanism. This second shaft is at a right angle with the entrance of the flexible shaft, and carries a simple two-bladed paddle wheel. The two blades project inwardly from their driving shaft, moving around the concentric well between the vanes of the barrel and the central worm on which the barrel moves. In this well is carried a liquid which as it is revolved by the paddles, acts as a drag on the vanes of the barrel. From this the barrel moves back and forth on its central worm in proportion to the drag on its vanes, the latter proportioning itself to the speed of the paddle wheel. The instrument also carries a trip and a total reading odometer. The Casgrain Speedometer is made by W. J. Connell, 36 Columbus avenue, Boston Mass

A Handy Tool.—Nothing facilitates repairs and adjustments so much as a tool that "is always on the job." Whether the work in hand be one thing or another, it is apt to consist for the most part of dismantling and reassembling and it is in these operations that a handy tool saves time and temper. One that

IRLAND PIPE WRENCH.

comes in this category is the Ireland pipe wrench, made by the Ireland Pipe Wrench Company, 15 Court Square, Boston, Mass. It has no slow screw adjustment, but is instantaneous in action and firmly grips anything that comes within its range without binding—features that are appreciated when adjustments are being made beneath the car. It is made in sizes designed to grip anything from a 1-8-inch wire up to a 1 1-2-inch pipe, with handles of lengths to correspond.

THE AUTOMOBILE

Grand
Prix
By
W. F. Bradley

tubular radiator passes from one side of the frame to the other in the form of an inverted U, the two seats are to the rear of this and the gasoline tank is carried astern. By looking under the radiator the driver obtains a good view of the engine; altogether the racer is compact and accessible and has the advantage of a perfectly clean underbody, for the entire chassis from crankcase rearwards is floored in by thin sheets of aluminum.

The Power Plant.

IT is never safe to prophesy about an automobile race, even if you know. One thing, however, that may be predicted with certainty about the Grand Prix is that the American representative will be watched with more than ordinary interest by constructors and automobilists on both sides of the Atlantic. In designing his car, Walter Christie has remained true to his first love and is more convinced than ever that a front drive and front steering machine is capable of holding its own against European chain or shaft-driven flyers.

No front-drive racer has ever been built in Europe, and, indeed, only one firm in the whole of France has attempted to produce pleasure or commercial automobiles of this type. The French racers in the Grand Prix are conspicuously alike and bear a close resemblance to the machines of last year, despite the radical change in racing rules. It remains for the foreigners engaged in the French race, and for the American entrant in particular to add a little interesting variety.

Grand Prix Racer Entirely New Production.

No part of the Christie machine which ran in the last Vanderbilt race has been used in the new automobile. Construction is on similar lines, but greater care has been taken in the selection of the material and a number of improvements suggested by past experience have been carried out. Specially imported Bischoff steel is used very largely in its construction, and many parts which last year were of bronze are now of this metal. The frame is of channel-section pressed steel, with rounded rear, wheel base being 100 inches and track 56 inches. The machine has not yet been weighed in its completed condition, but it is estimated that it will not scale more than 1,700 pounds. In proportion to its horsepower, it will be the smallest and lightest machine in the race.

Being both front-driving and front-steering, the entire motive power of the car is carried forward, the rear portion being absolutely free. The engine is mounted on a circular nickel steel crankcase, carried across the forward end of the chassis, the

circular steel crankcase across the frame fulfilling most of the functions of that organ. The four separate steel cylinders, 7 1-4 inches bore by 7 1-4 inches stroke, are bolted on the crankcase, staggered, with a distinct leaning rearwards. A copper water jacket surrounds each cylinder and a circulation of water is assured around the valves, all of which are in the cylinder head. The steel pistons carry three segments placed close to the head, and on the lower portion of the pistons are two bronze bearing-metal rings each about one and one-half inches in depth. Thus, though the piston and cylinder walls are of the

same metal, steel does not come in contact with steel. The piston heads are concave and carry on their

"CRADLED" GASOLINE TANK AND TIRE PLATFORM.

lower surface a number of radiating fins. All valves are in the head, the exhaust valves being mechanically operated by a rocker arm from a single camshaft mounted outside the crankcase and driven by an intermediate gear from the right-hand side of crankshaft. There are eight small automatic inlet valves for each cylinder arranged circularly in the cylinder head around the single exhaust valve. Over each cylinder head is bolted a manganese bronze inlet valve chamber, to which are connected the intake pipes from the carbureter.

Christie Machine Can Do Two Miles a Minute.

The engine speed is normally 1,000 revolutions per minute, accelerating up to 1,200 revolutions. As one revolution of the crankshaft corresponds to one revolution of the road wheels, the machine will, with the size of wheels now employed, be capable of doing two miles a minute. The Dieppe course being exceedingly fast, this ratio will doubtless be maintained if the practical fuel tests about to be begun accord with theory.

The engine is fitted with a Breeze carbureter modified somewhat to suit the racer. Lubrication is assured by a Pedersen pressure feed oiler. Ignition is by battery and Heinz five-unit coil. The commutator is also of Heinz manufacture. An ignition cut-out is provided on the steering wheel and spark and throttle levers are placed under the wheel.

One of the most interesting features of the car, and the one in which it differs entirely from its competitors, is the method of transmission and drive. Normally the drive is direct from the two-throw camshaft to the front wheels, one revolution of the shaft giving one revolution of the road wheels.

The machine being front steering as well as front driven, a universal joint is provided between each road wheel and the crankshaft. There are two manganese bronze flywheels, grooved and fitted with layers of woven camel's hair, which will give a perfect binding surface and which experiments have proved cannot be burned by slipping of the clutch. Chrome steel is used for the clutch, and this metal is also employed for the keyways, which on last year's machines were of bronze.

Change Speed Gear Shows Individuality.

One low speed and a reverse are provided by sliding gear mounted on the front of the crankcase parallel with the mainshaft. A gear is cut around the face of the flywheels, and for low and reverse drive the transmission is by gears from the crankshaft, through intermediate gears within the crankcase, to the sliding gear and pinion, meshing with gear on the face of the flywheel. All these gears are, of course, enclosed and are remarkably small. Front suspension is necessarily modified by the peculiar front drive, coil springs and a large rubber buffer being used.

There is no driving mechanism whatever rear of the dashboard, the rear axle, made of hollow steel, having only to support the weight of the car. Semi-elliptic springs are consequently employed, attached solid forward and shackled at the rear. Ex-

panding internal and contracting external band brakes, both woven camel's hair against steel, are mounted on drums on the rear axle. Breaking strain, however, comes on the distance rods and not on the rear axle itself. The rear brakes are operated by foot pedals, so placed that the two can be covered with one foot.

Water Cooling System is Distinctive.

The whole of the space between the engine and the dashboard is occupied by a Kell's tubular fin radiator in the shape of an inverted U passing from one side frame to the other. The rear-most radiator tube touches the dashboard, but to reduce the danger of breakage by vibration wood is interposed between the two. Between the lower tubes of the radiator and the side frame on which they rest a strip of leather is inserted with the same object, the radiator being wired to the frame by soft copper wire. A little improvement is noticeable here as the result of past experience. Instead of a single wire being wound through, which, if it should break, would leave the entire side of the radiator free, a separate wire passes between each tube to its hole pierced in the frame. The breaking of a few wires would not interfere with the stability of the radiator. Water circulation is assured by a bucket pump driven by bevel gears from the camshaft. The commutator is driven from the same shaft.

As everyone knows, the Grand Prix is run on a limited fuel allowance. No attention will be paid by the racing board to the weight of the machines or their mechanical features, but the tanks will be examined conscientiously. Walter Christie has placed the gasoline tank behind the seats within a rear cradle lined with

CHRISTIE RACER, SHOWING COMPACTNESS OF POWER PLANT.

wood to prevent friction between the two metals, and completely covered over by a metal shield screwed down for easy removal. The tank filler is the only portion which is exposed. For examination it is only necessary to take out the screws, disconnect the pipes and lift the tank out of its cradle. When all is closed up the metal box protects the tank and the fuel, the loss of even a small quantity of which in the race might decide between victory and defeat. The top of the tank cradle will also serve as a platform for spare tires. Twenty-five gallons of gasoline can be carried in the tank; as the total allowance for the race is about forty gallons, it will only be necessary to stop once to replenish the supply.

Christie Designs His Own Dismountable Rims.

Patent rims of Walter Christie's own design are employed, the feature of which is that there is no felloe, the hollow steel spokes, ten in number, bolting to lugs on the movable rim on which the tire has been previously mounted and inflated.

Engine control is obtained by spark and throttle levers under the steering wheel, the two brakes are operated by left-hand pedals and the clutch by a foot pedal to the right; this reversion of the usual method of placing pedals has been necessary to get a more convenient connection. Change-speed gear is operated by a side lever and the clutch can also be withdrawn by a side lever provided with a rack and notch for keeping the clutch out.

THE GRAND PRIX.

PARIS, March 28.—Ex- cepting the front-drive machine being built by Walter Christie, the Grand Prix racers are constructed on such uniform lines that a tabular comparison of their features is a simple matter. Of the 34 competitors, representing 15 firms and 7 nations, 17 have final drive by side chains and 16 have propeller shaft and rear live axle. The proportion remains about the same from year to year. Brasier, who last year constructed shaft and chain-driven racers, is still experimenting with the two types. Panhard, on the other hand, though building all ordinary touring machines with side chains, has decided to use propeller shaft drive again. In last year's Grand Prix 20 shaft machines started and three finished, the percentage of arrivals being 15. Fourteen chain - driven machines started and 8 of them, or 57 per cent., finished the race.

Makers seem to be equally divided on the qualities of high and low tension ignition. It will be noted that all machines, with the exception of Christie's, are equipped with magnetos.

Leather - faced cone clutches maintain their position, notwithstanding the attacks of different types of metal disc clutches. With such firms as Darracq, Brasier and Renault as its advocates, it cannot be said that the cone clutch has ceased to exist. Mercedes adheres to its particular type of spiral spring clutch.

Shock absorbers are used on nearly all the machines. Darracq and Renault, as last year, have built racers with no differential.

Carbureters are in each case the standard type used by the firms in their stock machines. Doubtless many minor improvements have been made here, for the Grand Prix is a fuel consumption race. There is nothing, however, that can be tabulated, and makers are not very communicative.

CHARACTERISTICS OF RACERS ENGAGED IN THE FRENCH GRAND PRIX.

MAKE	Driver	Type of Motor	Bore inches	Stroke inches	Horse Power	Ignition	Radiator	Cooling	Carburetor	Clutch	Change Speed	Drive	Weights Pounds	Wheelbase inches	Track inches	Rims	Particular Features
Bayard-Clement	A. Clement	4 separate steel jackets, copper cylinders, in pairs	6.2	6.2	125	Simms-Bosch h.t. Hisa	Mottard	4 cylinders, in pairs	4.1	4.7	30	Simms-Bosch h.t. magneto	Winged tube	Cent'f'l pump	Parallel currents	Hele Shaw metallic	4 speeds, sliding gear	Shaft	1700	106	53	V-sh'p'd h'd r'a- diator tubes on h.

The Grand Prix and the Sporting Commission Cup will be run together on July 2. All machines have pressed steel frames. Distances, 500 and 300 miles. Machines in the former event are allowed 6.6 gallons of gasoline per 62.1 miles; those in the latter race have 3.3 gallons per 62.1 miles.

AMERICANS IN BRITISH TEST.

LONDON, April 2.—Everybody was not satisfied with the flexibility competition organized by the Crystal Palace Automobile Club. The idea was good, but the rules had been too hurriedly drawn up and, as events proved, favored too much high-power machines. The program provided for a run from London to Bexhill-on-Sea, 60 1-2 miles distant, and return, to be performed on top gear. In addition all cars had to cover a kilometer flying start at highest speed, and travel over a distance of 110 yards on high gear at the lowest possible speed, it being of course forbidden to slip the clutch.

Of the fourteen entrants ten came to the starting line and there were three six-cylinder cars, six with four cylinders, and one with two cylinders. America was represented by the six-cylinder Ford and the two-cylinder Reo.

Three hours were allowed for the run to Bexhill, all cars arriving safely except the Porthos, the mechanic of which slipped while adjusting the pressure valve on the petrol tank, the car running at high speed, and had his foot crushed by the rear wheel. The mechanic got on board again, despite his injury, but the machine did not officially make the return journey. On a private motor track at the top of Galley hill the machines underwent the speed tests, covering a kilometer course. This accomplished, all attempted the slow test on the high gear without withdrawing the clutch. The event caused much interest and not a little speculation among the spectators as to the reason for a machine, which a few minutes before had been rushing by at fifty miles an hour, reducing to a crawl of four miles.

On the return journey River hill had to be tackled, which, owing to two bends about half way up, made it very difficult to climb without dropping into a lower gear. The Napier, indeed, was the only one to successfully negotiate according to regulations. The six-cylinder Ford, which up to this point had been equal to the British six, considering its lower horsepower, had to change gears and thus lost its position. The Reo, the only two-cylinder machine in the contest, did remarkably well, its fast and slow speeds being better than some of the fours, and even better than one British six, while it only had to change gears three times. The following table shows the bare results for each car; the number of points gained, which determined the official position of the competitors, is given in the last column.

Car	Fast	Slow	Engine	Gear	Marks
	Speed	Speed			
	M.P.H.	M.P.H.	Stops	Changes	
60-h.p. 6-cyl. Napier	57.69	3.48	nil	nil

24-h.p. 4-cyl. Porthos	34.28	7.70	withdrew.		

THE BOAT RACES AT MONACO.

MONTE CARLO, March 28.—The roar of exhausts now mingles with the murmur of the waves in the cliff-bound bay of Monaco. The first trainload of racers and cruisers arrived on a special train from Paris yesterday, are now being unloaded and tomorrow will have joined their voices to those already heard in the bay. Among them are the *New Trefle*, the Brasier production; *La Rapiere*, in which Panhard and Tellier have fond hopes; the *Pcnhard-Tellier*; *Pilot No. 1*, the steel kerosene-driven pilot boat; two from the Lorraine-Dietrich factory and a few cruisers.

Daimler II. and *Daimler III.*, the two formidable British racers, arrived a few days ago and are now undergoing trials in the bay. They are looked upon as the most serious rivals to the French craft, and will certainly be difficult to beat in rough water. The two boats are forty feet in length and are both owned by Lord Howard de Walden. *Daimler II.* has three Daimler six-cylinder motors of 90 horsepower; its companion, *Daimler III.*, has a couple of 90-horsepower six-cylinder Daimler engines. *Antoinette V.*, with its light twenty-four cylinder 360-horsepower engine, built by Levavasseur, of aeronautical engine fame, has been at work in the open and has given the impression of being able to lower all world's records. Italy's hope is placed in the *Itala* to be piloted by Henry Fournier and driven to victory by a 135-horsepower *Itala* motor. The boat is now in the water, but has not yet given an exhibition of her fastest work. In addition, Fournier will have his own boat, *Itala II.*

On April 2 the boats will be brought ashore and will remain on exhibition in the open-air show one week, racing to begin on April 7. Cruisers are classified according to length and cylinder displacement; racers are in classes according to length.

According to *Herald* cable reports from Monte Carlo, the racing programme opened on Sunday with a contest for 20-foot cruisers with a maximum cylinder capacity of two liters and a half, in which twenty-one boats entered. Barely one-fifth of these succeeded in reaching home under the required conditions. *Capoulou III.*, steered by Despoujols, was the winner; second and third positions were taken by *Nautilus-Mutel I.* and *Gamine*, respectively. The winner covered the 31 miles in 26 minutes less than the winner in a similar race last year.

A 31-mile race for 26-foot racers without any engine limitation united *La Rapiere II.*, steered by Tellier; *Itala*, steered by Henry Fournier; *Fiat IV.*, steered by Gallinari; *Seasick*, with Baron de Caters at the wheel, and *La Mowvette*, with Gallice as pilot. *La Rapiere II.* finished first, covering the 50 kilometers in 50:50, or at the pace of 54 kilometers an hour. *Fiat XV.* was second in 57:36, and *Seasick* third in 1:00:50.

The general impression is that the mark boats dragged slightly, for it is hardly thought possible that the *Rapiere*, swift as she is, could have traveled at 33.53 miles an hour. A stiff land breeze caused a postponement on the second day.

CECIL EDGE IN 6-CYLINDER NAPIER.

E. A. ANTHONY AND 6-CYLINDER FORD.

H. GORDON SHARP, 2-CYLINDER REO.

TRYING out a car, as it is termed by the men in the shops, is a decidedly strenuous form of automobiling, about which the average autoist knows little and can form but faint conception. It is the next to the last step in the long process of evolution, and regardless of the painstaking care attending every advance in the constructional processes and the numerous inspections to which every component must be subjected before being approved, the manufacturer is not willing to stake his reputation on the chance of something having been overlooked—or worse, the ever-present possibility of the unseen and unknown flaw. Every part of a motor is thoroughly inspected before assembling and the motor itself is given a thorough test before it ever reaches the car, but after the latter has received all its mechanism it must be tested as a whole. It is at this point that the tester steps in; his instructions are merely to try the car out. The post is one that is sought by every man at the bench and at the machine tools, for the tester is selected for his ability as an all-around man; he is under less restraint and is better paid than the rest of the men.

Trying Out is a Gruelling Process.

As soon as the chassis is no longer the subject of attention on the part of the assemblers and adjusters, a rough, unpainted seat is bolted on it and it is turned over to the tester to be put through its paces. Rain or shine, he takes it out shortly after 7 A.M., turns up at the noon hour for lunch, and, that over, again resumes the task, which may be likened somewhat to the breaking in of a fractious colt. Though there is usually a "fleet" of these testers at every factory of importance, and they hang together more or less, the job is more or less lonesome and the tester is always glad of company—but the guest is not always anxious to repeat the experience.

One morning last week the writer turned up at the Lozier works at Plattsburg, New York, and having made his mission known to Superintendent William Perrin, was assigned to "Test Car No. 1," this being the sole mark of identification it carried.

Well into the first week in April, one might reasonably have anticipated clear skies and a balmy atmosphere, but winter lingers on the shores of Lake Champlain, much of which was still covered with sheets of ice, and the weather as well as the temperature was more fitting for December than April. Sleet and snow alternated, and, borne on a driving northwest wind, did its best to detract from the small measure of comfort afforded by the perch beside the driver. The testing car carries as its sole ornament this pair of bucket seats, with occasionally a rough box bolted on the rear to accommodate tools—of either steps, footboard or running boards it is totally guiltless. You climb up and stay there as best you may. The driver has the clutch and brake pedals to brace himself against, the guest puts his feet where he can and braces himself like grim death against the suspicion of a footboard that extends below the dash—a bare two or three inches; the rest is yawning pit in which the flywheel and clutch may be seen whirring round—so smoothly as to convey but little hint of the actual speed at which they are turning.

With a quick shift into low, third, and then high, we are off in about the space of time it takes to tell it, and the motor is picking up rapidly over the rutty and frozen road. Before we had covered half a mile I had fully made up my mind that something essential had been omitted from the make-up of that car, and that something was the suspension. Lickety, bang, bang we bumped our way over ruts and thank-you-marms, at the sight of which the average driver would immediately declutch and slacken speed, the tools rattling and banging their way around the box on the rear and the guest doing his level best to maintain an average elevation between heaven and earth which would be bounded by the upper limits of the bucket seat.

Where, Oh, Where, Are the Mudguards?

Another half mile and we are beyond the town limits of Plattsburg; the low hum of the motor takes on a more business-like buzz and the wind and sleet cut keener. Then of a sudden two

CROSSING ONE OF LAKE CHAMPLAIN'S FEEDERS.

well-placed thumps on the back cause me to whirl around in anger, despite the precariousness of my position, to see what yokel has been hurling clods at us with such good aim. Just in the nick of time to make a deft duck and let an even more generous sized one go flying over my head. The driving wheels are the guilty parties; it had been thawing for a day or two previous and now a slight freeze has just congealed the mud enough to make excellent ammunition of it. Going at but the moderate pace of fifteen or twenty miles an hour, a five-inch tire can pick up half pound and pound chunks of the unsavory mixture and hurl it with a force and accuracy of aim that are truly astonishing—to the man who happens to be in their path. I glanced slyly at the driver to see if he were enjoying my discomfort, but his eyes were all for the car and the road, while his ears were strained to catch the faintest out-of-the-way sound on the part of the motor or transmission. I noticed, too, that his coat bore the marks of many a previous plastering of the same order, and said nothing. Then in quick succession two well-directed missiles about the size of three-pound shells landed with vicious plunks on different parts of the camera and I made haste to protect the lens.

"Too much mud for you?" laconically inquired the driver.

Between holding himself and the camera within the limits bounded by the semi-circle of the seat and attempting to protect my face from the cutting wind and the flying chunks of half-frozen "goo" that were landing about me with an unholy swat every now and again, I was too occupied to indulge in needless conversation. An unusually vicious bump sent me skyward just

at that time and in coming down my head piece wagged loosely, which must have been interpreted as a negation by the driver, as he resumed the business of seeing how hard he could make the car bump over that miserable apology for a road—at least, so I judged, for it was impossible to penetrate the all-enveloping hood and goggles. Anyone who thinks such trimmings savor unduly of affectation on the part of a driver needs but to put himself in the same position to appreciate their worth. On the finished car the mudguards blend with its lines and are part and parcel of the vehicle—their true value appears when they are not there.

Scant Time to Heed the Scenery.

We were flying along the edge of historic Lake Champlain with its numerous cedar-covered islands, now on top of a ridge which commanded a sweeping view and the next moment dipping into a ravine which shut the lake from sight, or rolling smoothly across a bridge spanning one of the many streams that empty into Champlain. On the other hand, a few miles back one gets an occasional glimpse of the foothills of the Adirondacks between the rifts in the scudding gray and the swirling snow. But it is a poor time to attempt to appreciate the beauties of scenery; if it be true that the average tourist sees little or nothing of the beauties of nature as he scorches along, it is doubly so of the tester. He has an eye for nothing but the road, and those who

"HOWDY DO!" AND "GOOD-BYE!"

accept an invitation to ride with him must perforce pay attention to other things more intimately connected with their momentary welfare. Thus it is that the scenery comes in for scant attention at best; bad ruts with their twisting turns are frequently interspersed with those transverse gullies that have been so aptly dubbed "thank-you-marms," and an occasional sharp turn adds interest and variety by calling for a bit of side strain that relieves the monotony of everlastingly pushing forward with one's toes on the narrow strip of board to maintain a hold.

A swish out of the beaten rut and we have shot around one of those right-angled turns into a country cross-road. Not expecting it, I sailed skyward when we crossed the ridges of the deep rut and centrifugal force kept me heading the same way when I came down, so that my feet missed the board but fortunately landed on the frame. There is always the alternative of dropping outboard under such circumstances, or sliding into the pit formed by the pan to protect the flywheel, clutch and transmission, but whether there is much to choose between the chance of hitting the grit over hard or being assorted by the rapidly whirling machinery is a question. Neither looked particularly inviting, so I concluded that one hand was enough for the camera and supplemented my strenuous and tiring foot brace by grabbing the back of the bucket seat. Bumpety, bump we flew over the rough and little-traveled surface, heading back from the lake and straight for the mountains. Just enough snow to make things

THREE OF A KIND: TWO "FORTIES" AND A "SIXTY."

slippery and a four-foot ditch on either side of the narrow, high-cambered road added an extra spice of danger. An untimely skid bringing up in the stagnant pool at the bottom of one of those ditches would have meant the end of that test run, for little short of a derrick would suffice to get the car back on the road again. But another mile or two of it and then we began to climb a bit, soon coming out on the road to Peru, N. Y.—a little town about twelve miles from the Lozier factory. This is an almost straightaway stretch of fine, hard macadam that formed part of the route of last year's Glidden Tour. It is here that the Lozier testers make their speed trials.

The Tester Knows No Speed Limit.

I thought we had been covering the ground at a very respectable pace before, all things considered, but once on the smooth way the driver opened the throttle, notch by notch, and the car fairly jumped ahead. There was still two-thirds of the sector for the throttle to travel, but we were flying along with the wind screaming by and the fine, hard grit from the road cutting my face like a whiplash. If the car ate up distance in that fashion

another of the swiftly traveling spots; it was a third tester and his car, this time coming our way. He had a "sixty" and we but a "forty," so that there was small use in trying to run away. With a rush he swept by us and we trailed in to the finish at Peru. A quarter of an hour later a third tester dropped in and they fell to comparing cars and swapping experiences.

Several Days Required for Thorough Tryout.

From the moment that the car is turned over to the tester until having received his final stamp of approval which precedes its wash-up, preparatory to shipment, its history is closely followed. Every drop of gasoline, oil and water that it requires are recorded—every hour that it is on the road and the mileage it covers during its novitiate are all carefully noted and the finished record is of considerable interest. Several days are required to complete the process, on each of which it averages about 100 miles or more over all kinds of roads and at the highest speeds of which it is capable. It is carrying but a relatively small portion of the load for which it is designed in the shape of body and passengers and its springs are stiff.

ON PICTURESQUE CHAMPLAIN'S SHORES—THE STAMPING GROUND OF THE LOZIER TESTERS.

with the throttle but a third of the way open, it seemed like tempting fate to make it possible to open it any more, and I instinctively hoped the muffled and immovable figure beside me, gazing straight ahead, would at least not attempt to fracture any world's records in the same informal way that legal speed restrictions had been strewn by the wayside.

But still another notch and a further spurt on the part of the motor until we seemed no longer to be traveling on terra firma. Anyone who wishes to realize the feelings of the driver of one of the cars in the Vanderbilt Cup race can do so with slight effort—the average tester will take him along, stretch after stretch, at better than a mile per and above a certain limit the sensations become dulled; there is no further appreciation of the rate of travel, regardless of how it be increased.

We were scudding along at this rate when a spot appeared around a bend down the road and came toward us at a similar pace; it was another of the Lozier testers. The slightest nod on the part of the drivers as the sole sign of recognition and we had passed with a swirl and a rush. With confidence born of familiarity, I half turned in my seat and "rubbered" back down the road we had just come over to see how fast the other fellow would disappear. He had hardly gotten a half mile away when he met

If there are any defective leaves or poorly fastened shackles it does not seem possible that they can fail to yield to the unmerciful grueling they are put through day after day on their test; that anything loose or defective can survive this treatment seems beyond belief, for it is putting it mildly to say that in each of its seances in the hands of the tester it receives far more and far harder service condensed into a few hours than it is apt to get in the same number of days at the hands of the average owner. If the latter be sensible, he takes advantage of every opportunity to save his car and his tires, but it is the tester's business to bring out the defects if they exist, and tires mean nothing to him. Not that it is any pleasanter a task for him to jack the unwieldy shoes off and on to replace a tube than for anyone else, particularly in the nasty weather that forms a large part of his lot—it is simply all in the day's work, and unfortunately punctures are many, far too many to please either the driver or the builder of the car, but there is no way to avoid them, and in view of the test that they are put to the wonder is not that they puncture as frequently as they do, but that they manage to stand up at all.

Testing is a strenuous occupation for both car and driver, and after a car has been through such a mill it may well be said that accidents due to defective parts are unavoidable.

HOW DROUGHT TAUGHT THE LAWMAKERS.

MILWAUKEE, Wis., April 8.—Educating legislators in autoing is quite a new proposition, but it was done with some remarkably good results a few days ago. Through the efforts of the Milwaukee Automobile Club and James T. Drought, a practical demonstration was given to the legislators of what the various speeds from six to forty miles an hour really are, and the ease by which an automobile can be stopped and controlled was quite a revelation to the majority of the members. The latter courteously consented to be taken for thirty to forty-five minute spins for practical demonstrations about the city of Madison.

Mr. Drought, who planned and executed this unique campaign, earned for himself the title "Star Lobbyist" of the 1907 season. He assisted greatly in getting and keeping the legislative body in good humor, so that they managed to look pleasant when a photograph was taken. In speaking of the idea recently, Mr. Drought mentioned that much of the credit for the effective work belongs to August Jonas and his Peerless, and Frank Roesler, a seventeen-year-old driver. These two skillfully and convincingly demonstrated the claims made in behalf of the auto, and many of the legislators saw a great light.

CONNECTICUT SUGGESTS LAWS CONFERENCE.

HARTFORD, Conn., April 8.—As a result of the two recent hearings before the Committee on Roads, Bridges and Rivers of the Connecticut Legislature there may be a conference of legislators from New England and adjoining States. It was Senator H. P. Buell, chairman of the committee, who suggested the advisability of such a conference, and he has written to the Secretaries of State of Massachusetts, Rhode Island, New Hampshire and New York, looking forward to a conference in the future.

Judging from the recent hearings at Hartford, it would appear that the Connecticut State Association of the A. A. A. will be successful in securing equitable legislation, there being no outburst of hostility and the committee showing by its attitude a desire to be eminently fair from the standpoint both of the automobilist and the public. Walter S. Schutz, the attorney for the Connecticut association, is at work upon a substitute bill, and,

being particularly fitted for the task, a measure is anticipated which should be satisfactory to the legislators.

At the first hearing the speakers included Mayor George M. Landers of New Britain, who advocates a State tax upon automobiles, providing the money is to be applied to the maintenance of the State roads; J. Howard Morse, president of the Hartford Automobile Club; Frank Miller, president of the Bridgeport Automobile Club; Colonel George Pope, Pope Manufacturing Company; H. P. Maxim, Electric Vehicle Company, and A. L. Riker, Locomobile Company of America. Charles T. Terry, chairman of the A. A. A. Legislative Board, made a splendid address, which included many convincing arguments.

Connecticut automobilists are discovering that a decided sentiment seems to tend toward leaving out entirely the rates per mile per hour, and make the speed provision dependent entirely upon the width, traffic and use of the highway.

HOOSIERS MAY HAVE TO REGISTER AGAIN.

INDIANAPOLIS, Ind., April 8.—The publication of the laws passed by the recent Legislature of this State has disclosed some facts in connection with the new automobile law not generally known. The law was hurried through the closing days of the session and very little attention was paid to it.

Probably the most startling feature that has developed is the one that will require all owners to obtain new registration numbers and in all probability to pay a second fee for registration. The new law changes the system of registration and, as the Secretary of State will be required to issue a new number, it is his opinion that a new fee will also have to be forthcoming.

PREDICTS UNCHANGED NEW JERSEY LAW.

NEWARK, N. J., April 8.—This is from the *Sunday Call*: "With the exception that there are not enough inspectors to properly care for the business arising from the enforcement of its provisions, the New Jersey automobile law which was passed last year has been found to work not so unsatisfactorily as was at first anticipated. Considerable tinkering with the law, through legislative enactments this year, was proposed, but it is not likely that any will be done."

CHAIN DRIVES AND THEIR CARE AND REPAIR

By VICTOR LOUGHEED.

PROBABLY no detail of automobile construction is more strenuously defended or more decidedly denounced than the chain drive, anomalous though such a condition may seem. And concerning nothing else in motordom has there been waged so long and vigorous a drawn battle as that between the chain and the propeller shaft, which never yet has failed to furnish occupation to the statisticians of the industry.

The real crux of the matter, when all comparisons are made and inconsistencies reconciled, seems to be that a chain drive is exceedingly good or astonishingly bad, according to how it is designed and taken care of.

Types of Chain Drives.

FIG. 1.

There are two common types of chain drives, the single-chain drive and the double-chain drive. The first is applied exclusively to rotating, or "live," rear axles; the second to non-rotating axles. Also, the single chain is now used only on small, light cars, while the double chain finds its chief place on the heaviest and most powerful machines.

The Single-Chain Drive generally conforms to the plan sketched in Fig. 1, in which *a* is the chain driving the rear wheels *bb*, through the sprocket at *c* on the rear axle *dd*. The motor is sketched at *e*, and it will be noticed that this type of drive requires the engine be placed crosswise of the car, so that its mainshaft is parallel to the rear axle. The drive is not necessarily to the center of the axle, as in the case pictured, some few cars having the axle sprocket located very close to one of the wheels.

The Double-Chain Drive, in its most characteristic form, is sketched in Fig. 2, in which *aa* are the chains, driving the rear wheels *bb*, directly through the sprockets *cc*, the rear axle *d* being non-rotating. The engine, *e*, is placed longitudinally in the car, so the power is communicated from it to the chains by the bevel gears at *f*, and thence by way of the countershaft *gg*, and the countershaft sprockets *hh*, which are just outside frame.

FIG. 2.

Much of the efficiency of the chain transmission is due undoubtedly to its flexibility and to the fact that it transmits power by a perfectly direct pull. A bevel gear, which has to transmit power "around a corner" cannot even in its best condition be quite as efficient as a chain likewise working in its best condition. As for the spur gear, which like the chain acts direct, its failure to show up as well in some tests may be due to the difficulty of maintaining the gears in the absolutely perfect alignment that is essential to the best results with this sort of machinery. A chain, on the other hand, will work just about as well with its sprockets material out of line as it will when every adjustment is perfect.

A great advantage of the double-chain drive is that it permits the use of a very light rear axle, which is relieved of the weight of the bevel and differential gears and therefore is little subject to the danger of bending from hammering over rough roads.

The Disadvantages of Chain Drives practically all result from the one difficulty of keeping the chains clean, though it is sometimes urged as an argument that the many parts and many

bearings of a chain constitute a not-inconsiderable complication. Also, it must be remembered that, whatever the efficiency of the actual chain drive itself, it is usually used in addition to all the gears and bearings that are present with the propeller shaft drive. The single-chain drive, of course, avoids this criticism.

The Different Kinds of Driving Chains.

There are two principal kinds of chains used in automobiles—the block chain and the roller chain. A third type—generally styled the "silent" chain—is used to some extent for a first drive from the engine, or under other conditions that permit of its thorough protection from mud and dirt.

The Block Chain is illustrated in Fig. 3, its characteristic feature being the alternation of the blocks *aa* with the pairs of links *bb*, *cc* and *dd*. Block chains are now little used for vehicle propulsion, except on bicycles and the very lightest automobiles, because when they are dirty the blocks wear very rapidly, besides wearing the sprockets in a similarly serious degree. This objection can be avoided by the use of chain boots.

FIG. 3. FIG. 4.

Roller Chains are of the sort shown in Fig. 4, being constituted entirely of links *aa*, *zz*, *cc*, *dd*, and *ee*, with small rollers *fff*, to work against the sprocket teeth.

Theoretically, any good chain, block or roller, will engage with and disengage from the teeth of correctly-cut sprockets without any sliding contact whatever. Practically, it is found impossible to cut sprockets to such perfection, besides which, if they were so cut, the least wear would spoil them. And films of dirt between chain and teeth would cause rubbing and wear. These various difficulties roller chains overcome by providing a smooth-working interior bearing, protected and lubricated, to hold off what otherwise would become destructive abrading forces. Theoretically, the conditions should be such that the rollers would not roll, but practically they do, which proves the necessity for providing the chain with them.

Silent Chains are of the general description sketched in Fig. 5, the teeth being on the chain links and the rollers, if rollers are used, being on the sprockets. Many silent chains work on toothed sprockets. Silent chains can be worked successfully in very much shorter lengths than prove practical with other chains, and can be built to run very fast and to transmit great power. Some of them are literally belt-like in width, being composed of multitudes of adjacent links.

The Material of Chains, while always steel, varies somewhat in quality. Since the highest possible quality is to be desired, most prominent manufacturers are now making chains of the better alloy steels.

Care of Chains.

Proper care, as has been suggested, is vital to success in the use of chains. It is not enough to have correct chains and correct sprockets—proper maintenance is as important as a proper start.

Commencing with a new car, the initial tension on the chain must be maintained, despite "stretching," by occasional readjustment of the radius rods. There is no such a thing as a chain really stretching, in ordinary use, in the sense of an elongation of the metal of which it is composed, but what does occur produces practically the same effect—a hundredth of an inch

FIG. 6. FIG. 7. FIG. 8.

wear at one hundred rivets making the chain an inch longer. In time, as the chain lengthens, it will have to be replaced, because the space from the bearing point in one link to the bearing point in the next will be so much longer than what should be a corresponding space between the sprocket teeth, that smooth operation will be impossible.

Replacement, in fact, is a very good and sensible policy with chain drives, to apply every so many miles, charging the comparatively small expense against the mileage, just as in the case of tires, fuel, etc. The best modern cars now are made with readily-removable sprocket rims, so replacement of the whole driving aggregation is as simple as it is inexpensive. And certainly nothing could be more expensive than to continue worn parts in use when new ones cost very little.

Protection of some sort, as by the use of chain boots, is much to be commended from every sound standpoint, though it is to be admitted that the generality of chain boots so far produced are somewhat unsightly. A simple expedient for partially protecting chains, which has been to some extent used with motorcycles, requires only a light, soft leather belt, stretched over the chain and allowed to run with it. A belt used in this manner will form itself over the chain until it protects all but the inner surface.

The Adjustment of Chains is very important, for, though a chain will run remarkably well when out of adjustment, it will run much better when in. A very loose chain is particularly bad, because when running it whips up and down in such a way as to flex and wear the joints very considerably. It is also likely to "climb" the sprockets, through a roller or block striking on the top of a sprocket tooth, and this occurrence will certainly result in a broken chain, if in nothing worse.

A chain too tight will wear itself and sprockets rapidly through the heavy stresses it maintains on all rotating parts, and it also is likely to respond so sharply in starting or accelerating as to break through the sheer suddenness with which it takes on loads.

To adjust a chain, a safe general rule to go by is to have it as loose as it may be without its being possible with a stick or rod to pry it free from the first tooth with which it is meshed on either front or rear sprocket.

To Clean a Chain, remove it from the car and, after wiping all surplus grease and dirt that can be removed with some waste or old rags, immerse it in a pan containing gasoline or kerosene—preferably the former, if quick results are desired. After letting the chain soak long enough to loosen the dirt on it, shake it in the fluid, or, if necessary, brush it with a coarse brush, until it is perfectly clean and every link works freely. If very dirty, a final rinsing with gasoline—whether this fluid or kerosene is used for the first bath—will expedite matters. When the chain is dry, it must be lubricated, preferably by working it around in a molten mixture of tallow and graphite—a compound that is to be had of any dealer in automobile supplies. In this way a sort of a bushing of graphite is worked into each joint, where it will remain and lubricate for thousands of miles.

Spare Parts for Chains, in the way of extra links, rivets, etc., always should be carried. Even a complete extra chain does not weigh much nor occupy much space, and always is likely to come in handy.

Chain Fastenings, by which the chain can be separated to remove it, take various forms. That shown in Fig. 6 is very common and very simple, consisting of a small bolt in place of one of the rivets, with a hexagon nut that can be easily removed. The system shown in Fig. 7 is in a way similar, except that an

FIG. 9.

elongated rivet is used to link together the chain ends, and is itself held in place by a split pin passed through a small hole in one end. The links in Fig. 8 are alternately provided with slots and headed rivets, so that they can be put together or taken apart by hand, but cannot separate when the chain is under tension.

Oftentimes, when a chain has stretched considerably, it becomes necessary to remove one or more links after the radius rods have been lengthened as far as they will go. To do this, it probably will be necessary to file off some rivet heads, unless the chain is made like Fig. 7 or Fig. 8 throughout its length, in which case the task is a simple one. Be sure not to remove a link before ascertaining whether or not its removal will shorten the chain more than can be allowed for by shortening the radius rods.

The Radius Rods and Their Adjustment.

Radius rods or some equivalent are necessary with all chain drives, to maintain a proper distance between the driving and the driven sprockets. The forward end of a radius rod should be pivoted at or very close to the center of rotation of the front sprocket, as sketched at *a*, Fig. 9. If pivoted as at *b*, Fig. 9—a construction seen on some old cars—the axle will swing along an arc different from the one that would keep the chain at the same tightness, as is shown by the dotted lines.

Radius-Rod Bearings require more attention than is commonly considered necessary and are adjustable or arranged for rebushing on many good cars. The constant motion wears them rather fast and when they are loose they cause a

FIG. 11.

destructive and annoying pound. Regular lubrication, preferably by a grease cup, is desirable.

Springs as Radius Rods are a not uncommon construction, as is shown in Fig. 10, in which the quarter-elliptic spring *a* serves to maintain the chain distance, its movement being practically along the dotted line *bc*.

The Adjustment of Radius Rods usually is effected by a turnbuckle, as at *a*, Fig. 11, or by a screwed-in end, as at *b*, Fig. 11. It is very important not to get the radius-rod adjustment on one side different from the other and if the chains vary in length it is better to have one too loose or too tight than to correct it by putting the rear axle at other than a right angle across the car. Measuring with a tape from front hubs to rear hubs will disclose any error in parallelism between the axles, if the steering is set for straight ahead.

Concerning the Sprockets.

Sprockets, like chains, should be kept as clean as possible, and renewed when worn. Some sprockets are made to reverse, so that they can be turned around and both faces of the teeth used. It is also important to keep sprockets as nearly in line as is possible, though a slight twist in the chains is unavoidable in running over rough roads, or if the rear wheels are cambered and the countershaft is straight. On some cars the countershaft sprockets are allowed some end play on squared shaft ends, to maintain alignment in swinging around curves.

Sprocket Size is very important—the larger the sprockets are within certain limits the better. Large sprockets increase chain speed and reduce chain pull for a given effort transmitted. Besides this, they reduce the angle or flexion between chain links, as shown in Fig. 12, in which the lines *a b* show the bending over a small sprocket, and the lines *c d* show it over a large sprocket, the gear ratio being the same in both cases. This point is of very great importance in reducing chain wear, because such wear is very closely in proportion to the amount of bending in passing over the sprockets. With larger sprockets all trouble from this source disappears.

LETTERS INTERESTING AND INSTRUCTIVE

Information Wanted Regarding Lava and Porcelain.

Editor THE AUTOMOBILE:

[690.]—Can you tell me through the columns of your paper the following:

What is lava as used in insulators for jump-spark plugs? What is the formula to make same in such forms; how is it hardened and by what process; how do they put a fireproof glaze on porcelain plug insulators, and what degree of heat is used, and what is the mineral used to make such a glaze; why is not lava better than porcelain, and which is the harder? Why is not lava more used than porcelain for automobile plugs?

A detailed answer in your next issue will be appreciated.
Buffalo, N. Y. W. De S.

We find your questions are somewhat out of our province and can hardly give explicit answers, but have no doubt that some subscriber to whose notice this comes may be able to supply the information desired. We have no idea as to the ingredients used in the composition of what is commercially known as lava, except that it is a sort of artificial stone, nor as to the process it goes through, but are under the impression that it is a proprietary compound and that the formula is a trade secret. There are innumerable formulæ for hard porcelain glazes such as you mention, according to the purposes for which the article is to be used, and according to the maker. The following is said to produce a very hard glaze, capable of standing a high temperature: Feldspar 18 parts, Cornwall stone 3 1-2 parts, whiting 1-1-2 parts, oxide of zinc 1 1-2 parts, and plaster Paris 3-4 part; we do not know how high a temperature is used. We do not know to a certainty, but think porcelain is the harder of the two, and have no idea as to why lava should not be the better material for the purpose. Your next question would appear to carry, not alone its own answer, but that to your previous one; we presume that if lava were a superior material from which to make spark plugs it would be used more commonly than porcelain. However, lava has been tried in several instances, so we have no doubt some reader who had had experience with plugs of this kind will come to our rescue by supplying a little more definite answer to the foregoing questions.

Some Queries Regarding a French Motor.

Editor THE AUTOMOBILE:

[691.]—Will you kindly explain under "Letters Interesting and Instructive" of what particular use is the communicating pipe "K" in Fig. 1 of motor under head "A New French Recruit to the Two-Cycle," on page 563, in the issue of March 28. Does the compression in "E," caused by the downwardly-moving piston "A," have any tendency to push down the second piston "B"? If not, would not two openings, one on crankcase and one at high point of entrance of pipe "K" be equally satisfactory?

Then again, what means are taken or could be taken (to advantage) to lubricate the inner wall against which piston "B" is bearing?

B. M. C.

The object of the pipe *K* is fully explained in the last paragraph of the description referred to, on page 554, in the issue mentioned. We presume the crankcase compression at *E*, caused by the descent of the piston *A*, may have a slight effect on *B*, particularly as the latter causes a certain amount of depression which would tend to increase this action. However, as mentioned in the description, its sole object is that of lubrication; as also outlined in the former, the oil in the crankcase is relied upon for lubrication almost entirely, by splash for the connecting rod ends and by means of the oil carried through *K* by the air circulation for the pistons. Just how this oil is brought into contact with the wall *F* against which *B* bears, does not appear, nor is there any mention made of it in the original French description, which leaves considerable to be desired in the way of detailed explanation.

Putting Copper Water Jacket in Place on Cylinder.

Editor THE AUTOMOBILE:

[692.]—Will you kindly let us know what you think is the best method of attaching an independent copper water-jacket as per accompanying sketch? The cylinders are cast in pairs and the jacket is too small to slip over either the base flanges or the heads

VIEW OF PROPOSED METHOD OF JACKET ATTACHMENT.

on account of the valve pockets. Would you wrap the jacket round the cylinder, making a double seam where the ends meet, and then calk the upper and lower edges into the grooves on the cylinder?

R. W. B.

Bryn Mawr, Pa.

It looks very much to us as if one or the other part of your design would have to be altered in order to carry out the project of using an independent copper water jacket as you propose, as we cannot see how you are going to make a serviceable joint in the jacket itself after wrapping it round the cylinders as you mention. It may be possible to do it, but considerable sleight of hand would be required, and it is doubtful if a good job could be made of it in this way. This would constitute a weak link in the jacket, even if it could be done without a great deal of trouble. It is customary under the circumstances, to make a jacket of one piece so as to be seamless, and slip it on over the lower ends of the pair of cylinders. Either a copper or a soft steel ring may be used for calking, this usually being seated under heavy pressure.

Obtaining Calorific Values of Different Fuels.

Editor THE AUTOMOBILE:

[693.]—Will you kindly inform me how or what formula was used to obtain the B. T. U. which is published on page 469, issue of March 14, in which is given acetylene equals 21,492 B. T. U. when it equals C_2H_2 and gasoline as 21,900 B. T. U. when it equals C_8H_{18} , alcohol equals 28,500 B. T. U. when it equals C_2H_5O , the alcohol must be less owing to the presence of oxygen.

Formulas for the three liquid fuels:

First: $8080C$ plus $34.462H$ per kilogram.

Second: $8080C$ plus $34.462 (H \text{ minus } 1/8 O)$.

Is not this correct?

R. C. MATLACK.

Chicago, Ill.

Your question as to what formulæ were used in obtaining the calorific values you mention is somewhat puzzling. We have never heard of the use of formulæ in this connection, the heat values of different fuels being obtained, as a general rule, by actual test with the aid of a calorimeter, of which the Junker and Sargent instruments are familiar examples. The alcohol referred to on this connection was absolute alcohol and, in consequence, of a very much higher heat value than ordinary commercial alcohol.

Bicycle Not a Good Foundation for Motorcycle.

Editor THE AUTOMOBILE:

[694.]—Will you kindly answer the following questions through your valuable journal and oblige a "would-be motor-cycle builder"?

I have a 1906 model Spalding (Nyack) bicycle, and am contemplating adding a gas engine later in the summer. Do you think the frame of my bicycle is strong enough to hold a gas engine, or would it be necessary to add an additional frame of strong iron pipe, or similar material, suspended from some point near the crown of the frame or the hub of the rear wheel? What would be the best means of transmitting power to the rear wheel? I have a coaster brake. Would it be possible to have a coil spring between

the front fork and the crown of the frame to avoid jars and vibration, or would you consider it more advisable to use a new front fork? Finally, where could I get such an engine that would fill the bill as to weight, etc.? Also, have you any idea as to the price of same, and could it be done any cheaper than to buy a second-hand motorcycle?
H. HART.

New York City.

We should certainly not recommend you to attempt to convert an ordinary bicycle into a motorcycle, for reasons which should be apparent to you on a moment's consideration. Take the matter of weight alone, say your bicycle weighs 25 pounds; the average light motorcycle weighs 110 pounds, more or less, so that it will be evident there is nothing whatever on your present machine designed to carry this weight, not to mention the vibration, which is a very important factor. You would need new spokes, new rims and larger tires as well as a new front fork and a new frame; after deducting these from what you have, it will be somewhat difficult to find any foundation left upon which to build a motorcycle. Of course, it is possible to strengthen the frame you have, but iron pipe is not exactly a suitable material for the purpose; your present wheels and tires might also stand the racket for some time, but the machine would be a poor one at the best and apt to prove dangerous, if it ran very long without shaking to pieces. Buy a second-hand motorcycle, and even though you have to be content with one of two or three years ago, you will doubtless find that its designer knew more about building them even then than you are apt to have acquired through observation; what is much more to the point, you will be considerably in pocket.

An Air-Driven Aspirant for Vanderbilt Cup Honors.

Editor THE AUTOMOBILE:

[695.]—Will you kindly answer the following questions in your "Letters Interesting and Instructive" column?

(a) Would a four-wheeled machine driven by air propellers and fitted with a type of aeroplanes for assistance at corners be classed as an automobile, and would it be eligible to enter the coming Elimination trials for the next Vanderbilt Cup?

(b) Would such a machine or would a car be allowed to carry three men in the race?
McG. D. & CO.

Philadelphia, Pa.

(a) As there is no precedent to be guided by in the matter involved in your first question, we can only give an opinion, but as there is nothing in the rules that prescribes the form of power nor the manner in which it is to be used to propel the car there seems to be little doubt but such a machine as you mentioned would be eligible.

(b) The rules restrict the crew of the car to two—the driver and an assistant or mechanic.

Unequal Compression in Two-Cylinder Motor.

Editor THE AUTOMOBILE:

[696.]—Will you kindly give me some information on the following: A customer of mine has a two-cylinder runabout; several months ago he scored one cylinder; I have had that rebored, now I do not get the power that I ought to. One cylinder is 1-8 of an inch larger than the other, yet I get the most power from the small cylinder. This car has only one carbureter; according to my idea I can't adjust the carbureter to suit both cylinders. I get good compression on both cylinders. Do you think by putting on double carbureters I will get the original power?

Columbia, S. C.

A. T. GIBBES.

We do not favor the idea of two carbureters, as it is extremely difficult to synchronize them so as to get the same results from each cylinder, the only designer that ever resorted to this expedient discarding it after two years' use. While you state that the compression is "good" in both cylinders, with nothing further to go by we are inclined to the opinion that it is not as good in the cylinder that has been rebored as it is in the other, and the only way to test this would be either by using a gauge or taking indicator cards of the two cylinders. The fact that one cylinder is an eighth of an inch larger than the other has little bearing on the case if the compression is poor in the larger one. You

do not mention anything about a new piston being obtained for the larger cylinder after the reboring operation, and if this has not been done no doubt the trouble will be found there. At all events it would do little or no good to multiply evils by attempting to make two engines out of one, which is virtually what you would be doing by using two independent carbureters.

Use of Pickling Solution as a Scale Remover.

Editor THE AUTOMOBILE:

[697.]—In a recent number you advocated the use of a 10 per cent. oil of vitriol (sulphuric acid) solution to clean radiators. Are you sure of your facts in this case? Even 10 per cent. oil of vitriol is very corrosive, it being the most corrosive of all our acids, and it seems to me that it would attack the copper and the solder of the radiator and the iron of the cylinders vigorously and do harm rather than good. If I am right, the recommendation by so prominent a journal of this measure would injure many cars. Please investigate your facts and let me know your results. The only other thing which I know of that works well is a strong solution of carbonate of soda, the washing soda of our household, not the bicarbonate, which is cooking soda.

Asheville, N. C.

CHAS. L. MINOR, M.D.

You are quite correct in stating that even a 10 per cent. solution of sulphuric acid is quite corrosive and will attack metal vigorously, but before it reaches the metal it must attack the furring or scale, and if the draincocks be opened occasionally and the solution drawn off as previously recommended, there is no reason why any injury should accrue. Naturally, if such a solution were poured into a radiator and permitted to stand over night, damage would be apt to result. The mixture is what is known as a pickling solution and is very largely used, particularly by electro-platers, for cleaning articles of brass or copper preparatory to plating. We do not recall the letter in the answer to which the statement you take exception to occurred, but if we remember aright, the request was for a cleaning solution that would be effective in a bad case. Carbonate of soda, especially when used hot, is an efficient cleaner, but there are probably many forms of deposits, such as those resulting from the extremely hard waters prevalent in the West, which would not be affected by it. If you wish to satisfy yourself that such a solution can be put into a radiator with perfect safety, make up some of it in a glass and put a few small pieces of sheet copper, brass and cast iron in the latter, and note the length of time it is possible to let them remain without being seriously corroded. Unless we are mistaken, we believe we recommended the inquirer to draw off some of the solution from time to time to note how it was working and to empty it out as soon as it ran clear, subsequently flushing the circulating system out thoroughly with fresh water to remove every trace of the acid.

What Causes One Cylinder to Make More Noise?

Editor THE AUTOMOBILE:

[698.]—I run a four-cylinder car of popular make, and of late I have discovered that one explosion of the four is considerably louder than the other three. This louder explosion is very much in evidence when the car is climbing hills on the high gear. I know which cylinder gives the louder explosion, which is No. 2, as I have held down the vibrators one at a time and when I hold down the No. 2 vibrator the loud explosion ceases. I thought it was the vibrator spring, so I put a new one in, but it did not help matters at all. I also have tested the plug in cylinder No. 2, and found it all right. If you can give me any light on the cause of this trouble I will be greatly obliged.

Westfield, Mass.

LELAND M. GILMAN.

Though apparently simple on its face, this is in reality a somewhat puzzling thing to account for. If the cams be not made integral with the camshaft, we should suggest taking a look at the latter at the cylinder in question. It may be either that the inlet cam has been shifted somewhat so as to give higher compression and a more violent explosion, or, what seems more probable, that the exhaust valve may have been moved slightly, causing it to open in advance of the

time intended, thus releasing the burning charge at a very much higher pressure than is the case with the other cylinders and making a correspondingly greater amount of noise. Then again, there may be a leak in the exhaust manifold at that cylinder, permitting the escape of the burning charge there, which would tend to make the explosion of that particular cylinder much more audible than the others. Naturally, the foregoing can only be surmises under the circumstances, and we should like to learn what you find to be the cause of the trouble.

The Easiest Way to Repaint an Old Car.

Editor THE AUTOMOBILE:

[899.]—I have a Pope-Toledo car with part of body aluminum, from which the paint or enamel is scaling off. I wish to have it repainted, but being too far away from skilled workmen in this line, I would be very thankful to be informed through "The Automobile" under the heading "Letters Interesting and Instructive" whether there are any prepared paints or enamels to be had that will wear and look well, and which can be applied by a fairly good carriage painter. If, in your opinion, there are such paints on the market, kindly give me the address of some firm in Chicago or Minneapolis from whom the same may be obtained. Also, will you kindly inform me thoroughly about the different coats, from prime coat to finish, and how best to remove the old paint.

Anamoose, N. D.

D. BRENDEL.

There are no doubt many good prepared paints and enamels on the market; you will find some of them advertised in our columns; write to the makers direct. We cannot recommend any of them from personal experience. Good carriage painting involves not only a great many coats, from ten to twenty or more, but also a great deal of care, and the directions involved would greatly exceed our space limits in this department, beside which we hardly think the subject is one of sufficient general interest to our readers. We should recommend buying a book on the subject. Unless you have a considerable fund of patience and leisure time, we should not recommend undertaking the job at all, as it is a very tedious one at the best. The easiest way would be to remove the body and ship it back to the factory, if the latter will do such work; if not, to the nearest carriage painter.

Christie Racing Car Steers by Front Wheels.

Editor THE AUTOMOBILE:

[700.]—Being a reader of your paper, I take the liberty of asking a few questions: Can you tell me whether the Christie car in the last Vanderbilt race steered with the front wheels, or did it steer with the rear wheels?

HARRY WALLACE.

Brooklyn, N. Y.

The Christie racing car referred to in your letter was steered by the front wheels the same as usual, as in fact has been the case with all the cars built by this designer, so far as our knowledge goes.

AN AMERICAN'S ADVICE TO THE "INVADERS."

Editor THE AUTOMOBILE:

[701.]—The American invaders do not expect to be received with open arms, of course, by their European confrères. However, I doubt if they quite realize the degree of hostility that the proposed invasion has provoked among the automobile clubs, as well as among the trade.

As an American automobilist living in France, I can only hope that the coming invasion will hasten the day when American automobiles will be found for sale in every French town. That would mean that the price of French cars had descended from its present lofty altitude.

When I look over the advertisements in "The Automobile" and see the ever-increasing numbers of high-powered runabouts and touring cars offered for sale at what seem here to be incredible prices, I sigh and think of what my poor little 10 horse-power runabout cost last year. The only consolation is that the same runabout costs \$500 more this year than last!

Thus the prospect of being invaded has my entire sympathy.

Judging from the comments of the Parisian press, our American invaders must not look for any good will or kind feeling,

either from the A. C. F., the trade, or from the police. I would, therefore, in friendship advise them to remember once they are in the enemy's country to be very careful not to fall into the hands of the cruel gendarmes nor of the rural gardes-champêtres, who, they may rest assured, will be in ambush for them. Let them make doubly sure that their "papers" are en règle: let there be no racing, especially through villages, and may they halt at the first intimation of anyone, in uniform or not. Otherwise they will make the acquaintance of the "contravention au vol," or, in other words, have their numbers taken, to be followed later on by arrest and fine.

Many villagee in Normandy, about here, have speed-limits of from 8 to 10 kilometres (5 to 6 miles) per hour. Here is where the wicked invaders are going to come to grief unless they are careful.

I do not wish to frighten any timid invader by speaking of Spanish roads, customs, and regulations. By the time they have got across France they will be sufficiently chastened and subdued to submit to anything!

I hope to be on hand at Havre when the invasion arrives. The city will not be illuminated, nor will there be fireworks, but we'll be there just the same!

This time next year there will be a lot of Americans who will know more about Europe than they do now!

As to whether the invasion will result in establishing a trade in American cars, remains to be seen. The French manufacturer already fears the coming of American competition. He is hoping that the poor performance of the American cars will react in his favor. At all events he has decided to ignore the invasion and to kill its evil effects by a "conspiracy of silence," in which he is being aided by the French press, automobile and otherwise.

Let us hope that he will be disappointed and that we soon may see the Avenue de la Grande-Armée lined with American auto shops filled with the marvelous runabouts of our dreams.

Vernon (Eure), France.

PEDALS.

A TANGIBLE OFFER OF HELP FROM KANSAS.

Editor THE AUTOMOBILE:

[702.]—In regard to a communication on page 515, of your issue of March 21, wherein a party from Baltimore, Md., signing himself, Subscriber, complains about carbon forming on the cylinder heads and pistons of an automobile motor, and asking for a preventive therefor, wish to say that while we do not know of any method of preventing this carbon from accumulating, we have found a very simple method of removing it from our own engine, and if his engine has the spark-plug in the center of the cylinder head, he can remove the carbon with a simple tool made for the purpose, in not to exceed ten minutes' time.

If the party has an engine with the spark-plug in the center of the cylinder head, we would be only too glad to send him instructions for making a tool to remove this carbon, or would loan him ours for trial use, in case he would pay the charges back and forth on the same, which would not exceed 25 or 30 cents by mail.

The writer never saw such a tool advertised, and does not think that there is one in existence, except the one he had made.

If all manufacturers of automobiles would make an opening in the center of the head of the cylinder of the dimensions and thread of a spark-plug, whether they used it for inserting the spark-plug or not, the matter of removing the carbon from the piston head would be reduced to such a trifling matter, and yet of such vital importance to the owner, the extra expense and trouble for so making the cylinder would more than be compensated for many times over.

Topeka, Kan.

J. M. PADGETT.

ANOTHER EXPLANATION OF THE MYSTERY.

Editor THE AUTOMOBILE:

[703.]—In answer to letter No. 636, in the issue of March 14, I would say that I have experimented to quite an extent with acetylene gas and generator, and find that acetylene gas leaves an explosive deposit on brass, copper, and silver, which will explode under very slight friction. This deposit seems to be greatly increased if the generators are overworked and the hot, freshly generated gas comes in contact with any of these metals.

This certainly was the cause of the explosions which occurred while Mr. Burtise was bending the copper tubes.

The writer was quite badly burned at one time, five or six years ago, while removing a copper spray pipe from a large generator, the deposit igniting causing the gas to explode, and has since often wondered why generator manufacturers use so much brass and copper under such circumstances.

I would, also, like to ask you how much loss of power there would be in compressing air in a receiver and using it in a simple engine such as is used for steam.

Hovington, Kan.

F. R. COVERT.

AMERICAN MAKERS AND THE EUROPEAN MARKET

R. E. MANSFIELD, U. S. consul at Lucerne, Switzerland, finds that the completion of plans for an American automobile tour through Europe this coming Summer has aroused unusual interest among European manufacturers and dealers in automobiles, concerning which he writes:

"Periodicals devoted to the automobile trade are sounding serious notes of alarm concerning what they are pleased to designate as 'the American automobile invasion.' It is not the tour alone that is causing the protest, but what is regarded as the 'presumption' of American manufacturers, who announce their intention of entering into competition with continental cars in the foreign field. There is a present and constantly increasing demand on the Continent for light and inexpensive motors, a type of car common to the American trade, but one that has up to the present been little exploited in Europe.

"In the construction of big, powerful, and expensive cars, France has always maintained the supremacy; but the increasing and almost universal interest in automobiling, especially in Europe, where good roads invite all classes to indulge in the pleasures of motoring, has created a demand for lighter and less expensive machines. This demand is practically ignored by the European, and especially the French manufacturers, and people who are anxious to enter the arena of the automobile world, to enjoy the delights of motoring at a nominal expense, are looking to America to supply the demand.

"The American manufacturers have arrived at a period when, by standardizing, they are in a position to turn out a machine better calculated to meet the requirements of the motorist, who uses a car for ordinary touring purposes and is content to travel at an ordinary speed, than are any of the European manufacturers, and at a lower price. If good, reliable, serviceable cars of from 12 to 16 horsepower, with touring body, hood, lamps, and tools, complete, can be placed on the European market at a cost of, say, from \$1,200 to \$1,800, according to style and finish, they will prove popular. It is a significant fact, and one that argues well for the American automobile, that many of the European factories, and especially the most modern plants, are equipped with American machinery and tools for the construction of motors.

"The prejudice against American automobiles which exists generally throughout Europe has been created and is maintained

largely by the continental manufacturers. This prejudice, which will continue as a factor in the trade for some time, can only be overcome or eliminated by a combined and systematic effort on the part of American manufacturers. It would not, perhaps, prove profitable for a firm representing one make of machines to establish agencies at various central points throughout Europe, but a general automobile agency representing several American manufactories could establish branches on the continent, where various types of machines could be kept on exhibition and where repairs and supplies for the motors might be kept in stock.

"Provision for promptly supplying repairs and replacing parts for damaged or broken machines is an important factor in considering the automobile trade in Europe. In the event of accident or damage to an American car, if there is no place where the repairs can be promptly supplied, the result is much delay, annoyance, and expense to the owner, which serves to strengthen the claim of the local dealers and manufacturers that it is advisable to purchase a motor manufactured on the continent, where repairs can always be promptly secured. For this reason continental agencies for American machines and supplies should enter into the calculation in the plan to invade the European market for automobiles.

Swiss Automobiles—Zurich Exhibition.

"There are in Switzerland many manufactories engaged in the production of automobiles, but there are no statistics available giving the number or value of motors produced annually in the country. The majority of the Swiss cars are high grade and also high priced. They are constructed especially with the view to ascending steep grades, as the country generally is hilly and mountainous. The automobile industry in Switzerland, while comparatively new, is making rapid progress, several new manufactories having been established within the last year or two. Among other machines produced in the country are various types of motor buses and wagons for transporting freight.

"The manufacturers of automobiles in Switzerland will give an exhibit in Zurich about the middle of May, which will be limited to cars made in the country. A list of automobile manufacturers and agencies in Switzerland is forwarded for the information of those who may be interested." [Copy of list may be obtained from the Bureau of Manufacturers.]

TAXIMETERS RENTED TO BERLIN CAB COMPANIES

CONSUL-GENERAL A. W. THACKARA, in answer to a Chicago inquiry, reports as follows on the use of taximeters on public carriages in Berlin and other German cities:

"With the exception of one firm, the manufacturers of taximeters do not sell the machine outright in Germany, but rent them to the cab companies or to the individual cab drivers. The rental is 5 marks (\$1.19) per month for horse cabs and 7 1-2 marks (\$1.78) for automobile cabs. For these rates the manufacturers deliver the taximeters to the cab owners and guarantee to the city authorities the perfect operation of the machines. The taximeters are given to the cab owners sealed, and neither the cab owner nor the driver is allowed to open the machine, such an action being punished by the authorities as a criminal offense. When the machines require repairs they must be returned to the manufacturers or their agents, who break the seals, make the repairs free of charge, and deliver the taximeters again sealed to the cab owner. To save time the taximeters requiring

repairs are left with the manufacturer or agent, who immediately replaces them with machines which are in good condition.

"The renting system is considered in Berlin as the most satisfactory for all the parties interested. The city authorities are insured against the possibility of the machines being tampered with by the drivers or owners of the cabs, the public is insured against overcharge, and the honest cab owners feel that they have nothing to do with repairs or care of the machine. Naturally the dishonest cab drivers prefer to own their own taximeters. When sold outright the prices for taximeters range from 200 to 400 marks (\$47.60 to \$95.20), depending on the number of schedules or combinations required."

June 1 to 17 has been settled upon for St. Petersburg's first auto show, to be well attended by the majority of the leading French firms. Italy, Belgium, and Germany, too, do not intend to be out of the running.

MA RTINI is a mountain car. The designation does not imply a freak machine built for impossible grades, for, as every student of European automobiles is aware, Martini is an automobile built on correct lines by the most skilled mechanical ability of Europe. Everywhere, however, is evidence of the hilly district in which it has its origin. Nothing is more calculated to develop good points in an automobile than a mountainous region, and it is these points which the Martini has inherited from its native Switzerland. In New York the machine is now handled exclusively by Palmer & Christie, of 239 West Fiftieth street, who are sole agents for the United States and Canada.

In this country the fifty-horsepower model is being sold in preference to the two smaller types constructed by the firm. With a wheelbase of 124 inches this gives room for comfortable side entrance open or closed bodies. The chassis is of pressed steel, narrowed in front to give easier turning and has pressed steel sub-frames, on which are mounted engine and transmission gear. Springs are long semi-elliptic both in front and behind with a transverse spring in the rear. This gives such an easy suspension that shock absorbers are unnecessary.

Engine. Cylinders, which are cast in pairs, are 4.9 inches bore by 5.9 inches stroke. The engine runs at 1,200 revolutions, is capable of being throttled down to 60 revolutions a minute and develop normally fifty horsepower. Valves are on opposite sides, mechanically operated, and all interchangeable. Timing gears are completely inclosed, run in oil and being fibre against bronze are very silent. Large inspection plates are provided in the crankcase, and the lower half of the crank chamber is readily dismountable without disturbing the crankshaft.

Ignition. A low-tension Simms-Bosch magneto driven off the inlet valve gear supplies the current for the make and brake ignition. Each cylinder is provided with a cut-out for verifying the individual units.

Water circulation is assured by centrifugal pump driven off the exhaust valve gear. The radiator is of the honeycomb type with a fan behind it driven by a belt off the main shaft;

the fan bearings are mounted on an eccentric permitting the regulation of the tension of the belt. The flywheel is also fitted with a fan. A cooling system capable of the hardest mountain work is one of the features of the Martini construction.

The carbureter is conveniently located on the right hand side of the engine, with induction pipes leading directly up from the mixing chamber to the two sets of cylinders. It is fitted with

an automatic air regulator, has a gauge screen to air inlet and is heated by a hot water jacket. By means of a small lever on the dashboard the supply of gasoline can be cut off between the float chamber and the mixing chamber, allowing pure air to be drawn into the cylinders and the motor used as a brake. The gasoline tank, carried at the extreme rear of chassis, is under pressure and is provided with a gauge indicating the exact amount of fuel. The gasoline is filtered before reaching the carbureter.

Clutch and Transmission. In the latest Martini model the clutch is of the leather-faced cone type, with a layer of rubber under the leather to give a more progressive hold. Transmission is through a countershaft, with drive to rear wheels through heavy side chains. The gear box is mounted on a sub-frame and provides four forward speeds and reverse, with direct drive on the high gear, all operated by a single lever with locking-gate device. The usual cardan joint is provided in the main shaft from engine to gear box. Ball bearings are employed throughout in the transmission gear, but are not used in the engine.

Brakes. The braking system of the Martini is the nearest approach to perfection it is possible to obtain. In addition to the arrangement already mentioned, by which the motor can be used as a brake, there are two powerful double-acting band brakes on the countershaft operated by separate foot pedals, and internal expanding brakes on rear wheel drums operated by a side lever. All brakes are steel on iron, and the pedal operated brakes are water cooled. If desired, the side lever for the rear brakes can be made to declutch the engine before applying braking power.

Lubrication is well thought out on the Martini. An automatic injection of oil to the four cylinders simultaneously

NO LAW FOR THE KING'S AUTO.

By PHARE.

PARIS, March 28.—The King's auto! What a degree of importance attaches to this designation. The Royal Motor Car! What an amount of privilege and prerogative is wrapped up in this titular term. Ordinary automobiles may fill the street and puff their petrol fumes into the nostrils of the entire population without securing any attention at all, aside from the instinct of self-preservation, but when the Royal or Imperial auto comes into sight it becomes what is known in journalistic eloquence as the "cynosure of all eyes" and looms up, by comparison, like a brand new buggy at the Ebenezer fair. The King's auto has more rights and privileges than a fire engine. It can do no wrong. If the Royal auto damages property or kills kids, the damagee or victim is royally honored, the amount of royal smashup or agony depending upon the altitude of the Royal Highness in question. To be run over by the regal limousine of a First Class Power is a high distinction, but to have your breast bone caved in under the touring car of a cheap republic or protectorate is only a vulgar street accident.

The carrosserie of the Royal auto corresponds to the body-work of the ordinary motor car, the difference being only in the name. The carrosserie of the Royal auto bears the crest of His Royal Highness. The Royal auto looks like any good-looking motor car until you come near and observe that it is labeled with a crest and no street address, instead of the name of Hank Hancock, with the street designation of 22 rue Skiddoo.

One of the European Royal Highnesses recently visited Paris—a frequent occurrence, moreover—and his chauffeur, while driving about the streets, was halted by the police and severely interrogated regarding his papers, of which he had none, and also with reference to his driving on the wrong side of the street. He couldn't speak the language, so he was marched off to the police station, where the usual explanations were given. By means of an interpreter it was soon ascertained that the prisoner was the King's chauffeur, the Royal driver, the pilot of His Majesty. Consternation among the police authorities! Humiliation for the policeman who made the arrest! Apologies and excuses! A terrible error had been made. The Royal chauffeur was at once allowed to proceed, and, as for his papers, permit to circulate, or privilege to drive on the right or wrong side of the avenue, all laws were off. As a matter of record, no experience of this kind happened to the chauffeur of the Royal Highness who recently visited Paris, but the fiction of it made an appropriate paragraph for one of the daily papers, showing how important are all things connected with the Royal auto.

THE POLICE AND THE MOTOR OMNIBUS.

Much has been written recently on the subject of the self-propelled omnibus, its advantages, disadvantages, and how it should be operated, says *The Engineer*. London has now over 850 of these vehicles on the road, and it must be admitted by the most biased critic that there has of late been a marked improvement in their working. The smoky exhaust which a few months ago was all-pervading has now ceased to exist to any considerable extent, while the noise of grinding gears and rattling bonnets has been greatly modified. Although the motor omnibus engineer has to be congratulated on these improvements, which came none too soon, Londoners have to thank the Chief Commissioner of the Metropolitan Police for the firm stand which was taken by Great Scotland Yard in refusing to license defective omnibuses. We are well aware that this severe discipline was not effected without hardships to many motor vehicle builders, but it was admitted by the representative of, perhaps, the largest firm of motor vehicle builders on Monday night, in the course of the discussion on Mr. Worby Beaumont's paper before the Society of Motor Omnibus Engineers, that the industry owed a great deal to Sir Edward Henry for the stand he had taken in the matter. Any other would have resulted in filling London's streets with an assortment of broken-down machines that would have worked irreparable injury.

DETAILS OF THE INTAKE SIDE OF MARTINI ENGINE.

is provided by a lubricator on the Dubrulle system driven by belt from the exhaust camshaft, with special leads to main bearing, pump bearing and fan. A supplementary hand injector pump is fitted to the Dubrulle to provide for the motor being supplied with an extra quantity of oil on heavy gradients. There is also a separate compartment in the lubricator for kerosene with a hand pump to force same through the cylinders for cleaning purposes. An arrangement is provided to keep the oil at a proper consistency under varying conditions of temperature.

Control. Spark and throttle levers on the steering wheel give complete engine control; in addition the clutch pedal automatically throttles down the engine as the clutch is withdrawn. There are four foot pedals; decelerator, clutch, and two separate pedals for the independent brakes on the countershaft. On the dashboard are carried the pressure feed gasoline pump, lubricator, lever for shutting off gasoline supply to allow motor to aspire pure air, water-cooling control for brakes, and switch. The steering gear is of the irreversible type, considerably strengthened on the new model, with connecting bar behind the front axle.

A complete dust pan from the front of the engine to the rear of the gear box protects the motor and all menchanical parts from projections from the road. Inspection holes are provided in the pan at convenient positions. The muffler is carried transversely between the gear box and the gasoline tank, with exhaust pipes projecting at the rear at each side of the tank.

Body work is in all cases supplied independently and according to the taste of purchasers.

EXHAUST SIDE OF 50-HORSEPOWER MARTINI MOTOR.

As a summer touring car, or runabout, the new Smith & Mabley Simplex Surrey has much to commend it. This type has all the advantages of a two-seater runabout, and with its 40-horsepower engine is capable of a fast clip, without the disadvantage of very limited seating capacity which may be objected against the former. As will be seen from the illustration, the surrey model is of graceful appearance and has all the lines of a fast roadster for either two or four people.

Examining the mechanical features of the machine, we find much that is of interest, the construction throughout being of the highest quality and very best finish. A pressed steel frame of usual channel section narrowed in front to give convenient steering is mounted on 53-inch by 2½-inch and 36-inch by 2-inch semi-elliptic springs, having respectively 10 and 7 leaves. Wheel base is 124 inches and track 56 inches. Tires are 935 mm. by 135 mm. and 915 mm. by 105 mm.

The four-cylinder engine, with cylinders cast in pairs, cylinder dimensions 5¼ inches bore by 5¼ inches stroke, is carried forward under the well-known S. & M. type of bonnet. Valves are on opposite sides and are all interchangeable. The engine is water cooled, circulation being assured by a gear-driven centrifugal pump, and the radiator being of the honeycomb type. A current of air is assured by a fan in the flywheel, the dimensions of which are 20 inches by 6 inches.

There is a double ignition system by Bosch high-tension magneto with automatic advance, and by storage battery and high-

tension distributor. The two systems are quite distinct, being provided with two sets of plugs and two-way switches on dashboard. An automatic carbureter renders the motor exceedingly supple and makes possible a wide range of speeds. Mechanical lubricator is employed.

The clutch is of the multiple disc type, now so popular on high-grade machines, the advantage of which is that there is practically no wear and that the load can be taken up more progressively than with any other type. Two speeds and reverse are provided by sliding gear of the selective type, operated by one hand lever on the side of the car. All gears are of chrome nickel steel cut on special gear shapers to produce a perfect line of contact. Final drive is by side chains from sprockets on the counter shaft to the rear wheels. The number of teeth on the countershaft sprockets is 23, 25 or 27; those on the rear wheel sprockets are 44. Diamond chrome nickel steel chains are 1¼ by ½ by ¾ inches. Direct drive is obtained on the high gear. Ball bearings are employed throughout in the transmission.

The braking system is very complete. On the rear wheels are two emergency brakes, 14 inches by 2 inches, of the internal expanding type, operated by lever on the side of car. Two pedal brakes on the differential, 11 inches by 3 inches, are operated by a foot pedal. The differential brakes are equalized and so arranged that in case one should get out of order the other can still be used. All brakes are absolutely protected from oil and are so constructed that no deformation can take place through heating.

INLET SIDE OF 50-HORSEPOWER SIMPLEX MOTOR.

EXHAUST SIDE OF SIMPLEX POWER PLANT.

MODEL H, 4-CYLINDER, 50-H.P NATIONAL RUNABOUT 1

THE motors used in Model H runabouts, touring cars and limousines of the National Motor Vehicle Company, are of the four-cycle four-cylinder type with separately cast, vertical, water-cooled cylinders 4.7-8 by 5 inches bore and stroke, developing 50 horsepower. The cylinders are mounted on an aluminum crankcase attached to a pressed steel sub-frame. Nickel steel admission and exhaust valves, all interchangeable, are mechanically operated by separate ball bearing camshafts, with valve levers adjustable to wear. The crankshaft is a steel bar hammered and bent into shape, revolving in five large imported D. W. F. annular ball bearings and has a ball thrust bearing at its forward end. The drop forged connecting rods are fitted with Parson's white bronze adjustable bearings, each bearing being held by four studs readily accessible through two large inspection ports on the side of the crankcase. There are four compression rings on each piston and exceptionally large hardened hollow wrist pins are employed. To dispense with keyways, the flywheel is bolted to a flange on the crankshaft.

Six and one-half gallons of water are carried in the water system and flat tube radiator, circulated by a gear-driven pump direct connected to the camshaft. A large ball bearing fan, mounted on the engine base behind the radiator, draws a powerful current of air through its entire area.

The aluminum leather-face cone clutch is fitted with eight flat springs placed under the leather in recesses cut in its face. These

permit the starting of the car gradually and eliminate sudden strain on the driving mechanism. Transmission is of the selective sliding gear type with three speeds forward and one reverse, giving direct drive on the high speed. Large annular non-adjustable ball bearings are employed on the main and counter shafts; the rear bearings on the main shaft are self-contained in a tubular cylinder and the whole enclosed in an oil-tight aluminum case.

An enclosed, sliding universal joint connects the main transmission shaft and the driving shaft, transmitting power from the motor to the rear axle in nearly a horizontal line. The driving or propeller shaft is enclosed in an extra heavy seamless tube brazed into the spherical gearcase and revolves on two rows of large annular type ball bearings. An excellent feature of the National Model H is the provision made for examining the driving gear and differential.

There are four powerful internal expanding double-acting hub brakes engaging 11 and 15-inch drums cast integral with the hubs of the rear wheels. Two of these are operated by a hand lever and the two others are applied by means of a foot pedal.

Double ignition is employed, with separate sets of spark plugs, one consisting of a gear-driven magneto with its high-tension coil, the other of a storage battery with single vibratory coil and distributor. A third combination can be made by switching the battery current through the distributor of the magneto.

FOUR-CYLINDER, 50-HORSEPOWER NATIONAL MOTOR.

DETAIL OF THE REAR SYSTEM OF THE NATIONAL.

THE JOYS OF THE TESTING RUN.

By AN OCCASIONAL OFFENDER.

Ever experience the joys—and other sensations—of a mid-Winter or early Spring cross-country testing run? If not, you still have much to learn—and it is all practical—regarding autoing. Possibly you are a seasoned driver, on whom, through excessive indulgence, the sport has begun to pall. Perhaps the novelty of guiding a swiftly speeding car has not yet given way to that matter-of-fact state of mind that comes with the passing of time. You may even qualify in the amateur class. It matters little, for, whatever your standing as an automobilist, a century run through a rural district at this time of the year will bring you face to face with conditions hitherto unknown, and your fund of knowledge will be appreciably augmented.

The requirements are not many—at the outset. The standard formula, epitomized, would read something like this: One country road, one bright day, one testing car, one good mechanic (if you are an amateur it is well to dignify him with the title of driver, permitting him to officiate in that capacity), heavy overcoat, boots and other paraphernalia sufficient to protect you from the pranks of the weather man.

Care should be taken to select, if possible, a machine fresh from the testing room, sans fenders, mudguards and body, aside

LOOKING BACKWARD OVER THE FROZEN ROUTE.

motor as it settles down to the task of plowing a path through a sea of mud that is contagious. One instant you marvel at the strength displayed, and the next accept the accomplishment as a matter of course, looking forward with all the eagerness of a trained warrior to new fields of conquest. Hills that from a distance seemed to present an effective barrier become commonplace. You note the ease with which the car winds its way through ruts and wish they were deeper so you could test the full power of the machine, forgetting that it is doing more than could reasonably be expected.

In the distance appears a farmer, driving a spirited team. There is an exchange of signals, the machine is stopped and you pick your way carefully along the roadside, take a firm grip on the bridles and assist the anxious ruralite in guiding his fractious steeds by the new terror. Another dash down the highway, past farm houses where snarling dogs dash forth madly and vainly pursue you, barking wildly at the exhaust, dodging frightened poultry scurrying for safety, startling the bovines resting peacefully in the barnyard. There is the wave of a hand at the tiller of the soil who suddenly emerges from the cavernous depths of the barn—for your farmer, be it understood, is at all times a sociable mortal; a fleeting glimpse of faces pressed against the windows of the farm house, for the passing of an automobile, particularly in mid-winter, is still an event, and you are once more amid solitude.

A mile down the road the "honk honk" of your horn arouses from their slumbers the occupants of a covered buggy, jogging along contentedly behind the family steed. A frantic waving of arms gives the wholly unnecessary warning not to attempt to pass, for the single track would make such a move on your part

WHEN THE AUTOS COME TO TOWN BY TWOS.

from the none-too-secure seat upon which the driver and one other daring mortal may find a precarious resting place. The advantages of such a course become apparent before many miles have been traversed, if you are desirous of taking the seasoning treatment in allopathic doses. The acrobatic stunts performed in what at times bids fair to prove a vain endeavor to maintain your seat as you jolt along over the rough roads at a lively clip, the unobstructed sweep of the wintry wind, the stinging blows delivered the exposed portions of your face as in the teeth of a gale the machine splashes through water half way to the hub, burying you beneath a coating of mud until all resemblance to anything human has disappeared—these are some of the things that cause you to speculate on whether it is really worth while. You jolt about, discovering anatomical points of contact of whose existence you were hitherto unaware; the seat comes up to meet you in your downward plunge with startling regularity, you splutter and say unkind things as a sheet of muddy water envelops you—and then, almost unconsciously, you find yourself entering into the spirit of the occasion, and the earlier discomforts give way to a feeling of exhilaration and a sense of satisfaction at the way in which obstacles are overcome.

And there are compensations in plenty for any inconveniences encountered. It is worth many times the effort involved to observe the manner in which seemingly impassable stretches of road are left behind. There is a cheerfulness about the hum of the

A SLIGHT VARIATION FROM THE BEATEN PATH.

disastrous. Meanwhile Dobbin plods peacefully along, keeping in the middle of the course, while you throttle your motor, reduce speed and indulge in some pointed remarks regarding the outfit ahead. Ever and anon there comes a warning, and it is with a sigh of relief you see a cross road loom into view. At last the suspense is over. The faithful steed is turned aside, you open up the motor, preparing meantime to go to the assistance of the distressed female if necessary. A burst of speed, a pair of bulging eyes peer out from under the cover, old Dobbin leisurely turns his head and surveys you, not even deigning to prick up his ears, and you discover that the fright was all in the buggy instead of ahead of it.

Incidents multiply with astonishing rapidity. The stop at a country store for a supply of rope fillers masquerading under the name of Havanas, the halt for lunch at a wayside inn, where curious throngs surround the machine and give utterance to exclamations of wonderment and advance strange theories, putting the best of joke books into the same class as the patent office reports when it comes to provoking hilarity, all contribute to the full measure of enjoyment.

But it is only when, tired and stiff, creaking in every joint, plastered with mud until you are unrecognizable, possessed of a ravenous appetite, you alight from the machine, upon completing the trip, that there comes an appreciation of what the car has accomplished, and your previous estimation of automobiles is revised upward.

It is all in the game, this seasoning process. You may never be permitted to share its joys, its sorrows—for they are occasionally encountered. But unless it has been your good fortune to participate in one of these cross-country tryouts your autoing experience has not been fully rounded out, and marvel as you may at the satisfactory performance of your car, your knowledge of the stages through which it progressed before leaving the factory will be incomplete. You can only know it as it is, and though you may have some conception of the many processes involved in its make-up, the chief essential is lacking.

ST. LOUIS' FIRST SHOW PRECEDED BY PARADE.

St. Louis, April 8.—This city is entirely new to the business of holding automobile shows, and in order to call public attention to the first event of the kind which was held there last week it inaugurated the practise of preceding the show by an automobile parade somewhat after the manner of the circus. This was held under the auspices of the Automobile Club of St. Louis, and first, second and third prizes were awarded in each of three different classes—for machines having the best decorative scheme generally, the best floral decoration and the best comic decoration. The start was made shortly after noon on Monday last, and the route covered many of the most important streets of the city, disbanding at Forest Park.

The show opened a few hours later, and though it is the first effort of its kind in St. Louis both the city and the sponsors of the affair may well be proud of its success. The Jai-Alai Building offered about the only suitable housing for the affair, and its 20,000 square feet of floor space were taken advantage of to the best effect. Forty-four spaces were laid out on the main floor and were devoted entirely to complete cars. There was an overflow of cars in the annex, together with a liberal showing of motor cycles and motor boats. The balconies were turned over to the dealers and makers of accessories and parts, while that ubiquitous side-show—the moving picture exhibit—was also on deck. The main floor and annex mustered 29 exhibits of cars in all, with 14 accessory exhibitors, which, together with those of motorcycles and boats, brought the total up to 45. Contrary to long-established precedent, Monday was the opening day, although the show was in readiness and the doors could have been thrown open the Saturday night previous. The decorations were of an attractive order and well installed, the predominating motive being white, which was used as a floor covering, with flags and bunting to set it off, not to overlook the suspended balloon, for St. Louis wishes to assert her pre-eminence in the aeronautic field. The attendance was extremely satisfactory on the opening night.

INTERIOR OF THE HUGE JAI ALAI BUILDING, WHERE ST. LOUIS HELD ITS FIRST AUTO SHOW LAST WEEK.

THE SCIENTIFIC REGULATION OF TRAFFIC*

By EARL RUSSELL.

I AM fully aware that the scientific regulation of anything and the application of the principles of logic to legislation are naturally abhorrent to the mind of every Englishman. I am also fully aware that the recommendations and suggestions which I shall venture to make have no prospect whatever of being carried into operation in practice. Even so, I think it may be worth our while to consider for a short time what ideal regulations might fittingly be made to control the traffic of this country. The validity of one objection I fully admit, and that is that no paper schemes can carry any real weight until they have stood the test of experience. But some of the obvious faults of a scheme emanating from an individual may be removed by the full discussion and candid criticism which it will no doubt receive from many of the experts in this room. Let us then consider the ideal regulations that could be framed for traffic if we had the minute law-making and law-abiding character of the German coupled with the logical mind of the doctrinaire Frenchman.

Let me first then lay down certain postulates upon which to rear the logical superstructure. I do not wish to suggest that the postulates themselves might not be open to attack (in this age even Euclid is not sacred), but it is necessary to begin somewhere, and to take as our major premises some things on which we may be supposed to be agreed. I postulate therefore:—

1. That the primary object for which the money of the rate-payer is spent upon roads and streets is to provide channels for traffic.

2. That such traffic consists of vehicles of various classes, pedestrians and animals moving from one place to another place.

3. That it is an advantage to the community that such traffic should be conducted:

(a) With safety;

(b) With celerity;

(c) Without congestion or friction;

(d) With the minimum of expense or effort to the traffic itself, and with the minimum of burden to the rate-payers.

Next let us consider the classes into which this traffic may be divided for the purpose of this discussion, say, for example:—

A. Fast-moving traffic; including motor cars, motorcycles, bicycles, and gigs, hansom and broughams fitted with rubber tires.

B. Moderately fast traffic; including tradesmen's carts, light delivery vans, railway parcel vans, post office vans, and all classes of omnibuses—generally, in fact, all vehicles which habitually move at speeds between seven and twelve miles an hour.

C. Slow traffic; such as carters' carts, heavy vans, farm carts, traction engines, and the like.

D. Pedestrians; including dogs walking to heel or attached by a leash and led horses.

E. Animals; including cows, sheep, pigs, dogs not under control, donkeys, and all domestic poultry, and horses running loose.

It is obvious that the problem differs greatly in complexity and difficulty in town and in the country, and it would be convenient to take the country first. I do not think it can be said that the by-roads of the country are so full of traffic that any special regulations are necessary. All that is required is that fast vehicles should be driven with care, and that no persons should come round sharp corners on the wrong side in a reckless manner. Let us, then, exclude all by-roads in the country from our consideration, and confine our attention to main roads. The first observation to be made about the main roads in this country is that they would be much better for a little engineering. In their present form, with unnecessary hills, unnecessary corners, bad material for the road surface, carelessness in camber and super-elevation, they are a standing disgrace to a civilized and wealthy country, and they entirely fail to fulfil the conditions required by Postulate 3 (d). The ratepayers pay a larger sum than is necessary for the upkeep of a properly-made road, and the

users of the road have a more expensive and a more dangerous track than the configuration of the country requires. However, my purpose is rather to discuss the traffic itself than the roads upon which it runs; and the following are the regulations that I would suggest for traffic on main roads in the country:

1. Danger is caused by sharp corners; therefore, every such corner should be indicated by a sign, and every person or vehicle should keep to the proper side of the road at all times, and should not overtake another vehicle going the same way at corners. The corners themselves should be softened where possible, and hedges and other obstructions to the view should be removed.

2. Danger is caused by the unexpected emergencies of vehicles from a side road, and no vehicle should therefore be allowed to come from a side road on to a main road without coming to rest. Where two main roads cross, the speed should be reduced to ten miles an hour, or less in the case of horse-drawn vehicles.

3. The presence of animals not under control, or under imperfect control, upon the main roads is a danger, and no person should, therefore, be allowed to drive flocks of sheep or herds of cows upon a main road without the assistance of a second person at a distance to signal approaching vehicles and to assist in controlling the animals. Nor, as a general rule, should animals be allowed upon the main road at all between 9 A. M. and sunrise next day, except on the market day of the particular town. It would not, of course, be necessary to apply this prohibition to a single cow or single pig or single sheep, which was under adequate control by a rope or otherwise.

4. Pedestrians on main roads are dangerous both to themselves and to fast traffic, and where possible a raised footpath should be provided for their accommodation. In the absence of a footpath they should walk upon the side of the road facing the approaching traffic. Children playing or persons gossiping in the main road should be subject to heavy penalties for obstructing the traffic.

5. No person should be allowed to drive a vehicle on a main road without possessing a license, to be granted after examination in the regulations, and to be revocable for misconduct.

6. All vehicles traveling at night should be lighted both back and front.

By the adoption of regulations such as these fast motor cars could travel with safety to themselves and others on all the main roads of the country, and the average speed and comfort of all travelers upon the main roads could be sensibly increased, while I venture to say that the number of fatal accidents and personal injuries due to vehicles, whether motor or horse-drawn, would be decreased by something like three-fourths.

The alternative suggestion of motor tracks throughout the country has its fascinations both for motorists and their assailants. But with the precautions I suggest, it would be possible with safety on main roads of good surface to maintain an average speed ample for all requirements. Moreover, it is not good economics to incur expenditure—no matter who finds the money—which can be avoided by making a proper use of the plant you already have. From the tourist point of view a straight motor way, with no obstructions, would be very tedious, and only of real use to powerful cars going long distances in a hurry, or to passenger cars. For every thousand pounds per mile spent on the construction of the road, sixty-six cars per day, all the year round, at a toll of a penny per mile, would be required to pay interest and depreciation, not considering working expenses.

We now come to the much more difficult question of regulation in towns, and as we are all familiar with London, it will, perhaps, be convenient to take it as an example. The trouble from which traffic suffers in London is chiefly that of congestion, and this congestion is due to various causes. Sometimes, but comparatively rarely, it is due to the fact that a larger number of vehicles wish to proceed along the street in one direction than the street is physically able to accommodate. More often it is due to a string of vehicles being held back by some slow-moving vehicle in front, and being unable to pull out and overtake it on account either of the presence of central standards, or of a

*Paper read before the Royal Automobile Club of Great Britain and Ireland.

vehicle coming in the opposite direction. The dangers in London do not seem great, on account of the slow average speed of the traffic, except at night, when the streets are comparatively empty, and hansoms and other fast vehicles may often be seen dashing round right-angled corners on the wrong side. In spite, however, of the comparatively slow speed, there are very many numerous accidents, indeed, in London. The cost of the delay to traffic has often been roughly estimated by writers, but none put it at less than several million pounds in the course of each year. The making of new streets or the widening of existing streets is an enormously expensive process in any large town, and any scheme which doubles or trebles the existing capacity of the streets without any cost to the ratepayers *ought*, therefore, to receive enthusiastic support. What, then, is the remedy? In the first place, if the greater part of the confusion is caused by the mingling of traffic of all sizes and all speeds, let the traffic be separated into three classes, A, B, C. In the second place, let every wanton obstruction of the street space in the shape of refuges and cab ranks in the middle of the street be swept away, and, as a consequence of this, it will be necessary for the safety of the traffic itself to provide that it shall flow only in one direction, and for the safety of pedestrians it will be necessary to provide either bridges or tunnels. If traffic in any given street is to be only in one direction, it follows that some parallel route must be found to accommodate the traffic in the reverse direction. The danger from corners can be almost entirely abolished by causing all corners to be taken on the near side, and where this is not possible an inlaid white line should be put in the street surface which would have the effect of preventing a vehicle from cutting the corner. Imagine the pleasure of having no refuges and no traffic in the opposite direction to look out for, no danger in pulling to the off side to overtake another vehicle, no difficulty in keeping to the curb because of the vehicle already standing there. Picture also the diminution in accidents owing to nearly all corners being turned on the natural side, and the few exceptions being turned in such a manner as to make a collision almost impossible. Of course, a necessary incident of such a system would be that every driver should be licensed, and should pass an examination in the regulations applicable to London traffic. Having disarmed my critics by insisting so frequently upon the Utopian character of these proposals, I append for my own satisfaction a draft bill showing how easy it would be to give legislative effect to them, should the community ever decide to conduct its traffic on business principles.

AN ACT FOR THE REGULATION OF TRAFFIC IN THE UNITED KINGDOM.

PART I.—COUNTRY.

1. A person in charge of a vehicle upon a main road shall keep upon the left or near side of such main road and shall not at any time permit the off side of his vehicle to project more than two feet beyond an imaginary line drawn along the center of such main road except for the purpose of overtaking another vehicle going in the same direction.

Provided that he shall not overtake or attempt to overtake any other vehicle going in the same direction within fifty yards of any corner on such road which would prevent traffic approaching in the other direction from having a clear view.

2. Any person in charge of a vehicle on a main road who is overtaken as provided in the last section shall keep his left or near wheel within not less than one foot of the edge of the metaled portion of the road.

3. No person in charge of a vehicle shall come upon a main road from any other road without bringing his vehicle to rest at the junction with the main road.

4. No person shall suffer any animal which is not under the control of some person to be or remain upon any main road between the hours of 9 A. M. and sunrise on the next day.

Provided that this section shall not apply on market day within ten miles of a market town to animals being driven to or from market under the charge of some person with the assistance of a second person to warn approaching vehicles.

5. No person in charge of a vehicle on a main road shall cross another main road without reducing speed and taking such other precautions as may be necessary.

6. No person on foot shall walk upon the metaled portion of a

main road at a greater distance than three feet from the right hand edge of the metaled portion. No person on foot shall be permitted to loiter or play games upon the metaled surface of any main road.

7. (1) A person shall not drive or conduct a vehicle on a main road unless he is licensed for the purpose under this section and a person shall not employ any person who is not so licensed to drive or conduct a vehicle.

(2) The provisions of Section 3 (2) (3) and (4) and of Section 4 of the Motor Car Act 1903 shall apply to the granting, endorsing and suspending of licenses and the disqualification of license holders so far as applicable as if the word vehicle were substituted for the word motor car.

(3) The authority granting the license shall examine the applicant in such way as they may think fit and may for this purpose appoint any person or committee as examiner or examiners and pay such fees as they may fix, not exceeding 5s. per candidate.

PART II.—TOWNS.

8. In boroughs exceeding in population 250,000 the Local Government Board may, on the application of the Town Council, declare the whole or a limited portion of the borough or certain specified streets in the borough to be a special area.

9. (1) In such special areas it shall be lawful for the Town Council to make such regulations for traffic to apply during the whole or any specified portion of the day providing inter alia:—

(a) For defining or limiting the classes of traffic to be allowed along particular streets;

(b) For traffic to be limited to flow in one direction only;

(c) For prohibiting the loading or unloading or stopping of vehicles in the street;

(d) For regulating the routes and stopping places of omnibuses and for providing standings for other public service vehicles.

(e) For marking the centers of streets and the angle at which corners may be turned by vehicles where necessary;

(f) For any detailed regulations ancillary to the above.

(2) Any regulations made under this section may be altered, amended or added to at any time.

(3) Regulations made under this section shall not come into force until one month's public notice has been given by posting in the streets to be affected and by publication in the newspapers circulating in the district.

(4) Regulations for driving traffic into five classes to be known as fast traffic, moderately fast traffic, slow traffic, pedestrians, and animals, shall be made by the Local Government Board. Any dispute or difference as to the class of traffic to which any particular kind of vehicle or animal belongs shall be settled by the Local Government Board, whose order shall be final.

(5) A copy of all regulations in force shall be given to every person who receives a license under Section 10.

10. A separate license, to be granted and obtained in the same manner and subject to the same provisions as enacted by Section 7, shall be necessary for any person in charge of a vehicle in a special area, and no person shall be entitled to drive or conduct a vehicle in a special area by virtue of a license granted under Section 7, but a license under this section shall be valid for any special area.

SPECIAL PROVISIONS APPLICABLE TO LONDON.

11. The area contained within a radius of four miles from Charing Cross shall be deemed to be a special area within the meaning of Section 8, and shall be called the Metropolitan Special Area.

12. The powers exercisable by a Town Council under Section 9 shall be exercised within the Metropolitan Special Area by the Commissioner of Police for the metropolis, with the advice and consent of the London County Council.

PART III.—GENERAL PROVISIONS.

13. No person shall be entitled to recover damages for loss or injury to any vehicle or animal if at the time of the happening of such loss or injury the vehicle or animal was suffered by the owner or person in charge to contravene any of the provisions of this act, or of any regulations made under this act. In any civil action proof of such contravention shall be sufficient to establish liability without further proof of negligence, and shall entitle any person who has suffered loss or injury owing to a contravention in respect of any vehicle or animal to recover damages as if negligence had been proved.

14. Any person failing to observe any of the provisions of this act or any regulation made under this act shall be guilty of an offense under this act, and shall be liable on summary conviction in respect to such offense to a fine not exceeding £50, or in the discretion of the court, to imprisonment not exceeding three months.

15. It shall be lawful for any local authority to incur expenditure in advertising or posting the provisions of this act or of any regulations made under this act.

16. (1) In this act the expression "vehicle" shall mean anything running on wheels other than perambulators and wheel-barrows.

(2) This act may be cited as the Traffic Regulation Act, 1907.

HELPFUL HINTS FOR THOSE TOURING ABROAD

By W. F. BRADLEY.

If a tour through Europe involved no more formalities than a run to Chicago, automobilists would not hesitate long before deciding to cross the Atlantic. But the prospect of a voyage to France, Italy, Germany, and other countries of the Old World brings visions of customs officials, registration laws, duties, any of which slighted may entrain undesirable acquaintance with the merciless gendarme. In reality touring through the old country is no more difficult for an American than for a native, if only advantage is taken of the facilities offered by the various European associations and clubs for those who travel by automobile.

Nine-tenths of the Americans who make an automobile tour through Europe start from France. Some account, then, of how French associations aid automobilists will be of use to the greatest number. The Touring Club of France, the largest organization of its kind in the world, renders invaluable aid to the foreign visitor. By an understanding between the American Automobile Association and the T. C. F., any member of the former can become a member of the French body on simple request in writing and a payment of the annual fee of one dollar. One of the most valuable services the T. C. F. can offer is the entry of the machine into nearly all European countries without any formalities at the customs house.

To Obtain the Greatest T. C. F. Convenience.

Thus a member before leaving New York could arrange for his automobile to pass into almost every country in Europe merely on presentation of a paper known as a tryptique. To obtain this, particulars of the car must be furnished and the amount of custom duty levied by the countries about to be visited deposited with the club, which amount will be refunded by the club at the end of the tour. If the traveler knows what his plans are a couple of months in advance, he can arrange all this before leaving home and pass from one European country to another more easily than here from one State to another.

At the club's headquarters in the Avenue de la Grande Armée, Paris, maps and guide books dealing with every quarter of Europe in which the tourist has, or ought to wander, can be consulted and purchased. In addition there are always secretaries present to give advice on routes and aid in mapping out tours. There are quite a number of general advantages which the T. C. F. bestows on all who have the traveling habit, whether they pay their annual dollar or not, such as sign posts, improved roads, improved hotels, and generally improved conduct on the part of those who own the hotels.

Benefits Obtainable from the A. G. A.

If the automobilist intends starting his tour from Paris, and a very large number do, notwithstanding the evil reputation which the roads in the neighborhood of the capital have earned (which reputation, by the bye, is most frequently due to the mistakes of strangers in picking out old paved roads instead of the more indirect macadamized surfaces) he can obtain considerable benefit from membership in the Association Générale Automobile. This body is an offshoot of the Automobile Club of France, and has its offices in the same building.

One of the first and one of the most important matters on arriving in France is to obtain a driving license. Ordinarily this will involve a delay of two or three days, according to the idea the official has of the value of time or his inclination to work. The A. G. A. is empowered by the national authorities to hold examinations and grant temporary operating licenses, which can be exchanged at leisure for the official document. A stranger arriving would present himself at the Association headquarters with his car, a few unmounted photographs of himself, and the

necessary documents to prove his identity. Immediately an examiner takes him in hand, and, if satisfied with his ability to handle an automobile, grants him a certificate which will be accepted by any sergent de ville or gendarme in France, or almost every other country of Europe for that matter. When the clerks in the Mining Department have gone through their leisurely routine the official papers will be forwarded to you, probably three weeks later, but so long as you have the A. G. A. license in your breast pocket you can look any man—or gendarme—in the face. The A. G. A. is also empowered to issue the tryptique to its members, as is done by the Touring Club of France.

How the A. G. A. Recommends and Supplies Chauffeurs.

Many an American has engaged a chauffeur in Paris—and regretted it. There are a special class of polyglots hanging around the garages of the gay city who find it easier to get an operating certificate than a good character recommendation. American millionaires are their best friends. If a member of the Association Générale Automobile, you can obtain a chauffeur whose ability has been proved and whose moral character is vouched for by that body. The A. G. A. keeps close watch over the men it recommends, causes them to report to headquarters whenever out of employment, and withdraws their diploma on any proved case of misdemeanor.

Further advantages of the association are information on tours, maps, etc., a discount on tires, spare parts, and automobile assurance, by arrangement with a number of firms. The annual subscription of the association is \$4, reduced to \$2 for members of the Automobile Club of France or affiliated bodies. In a conversation with the secretary of the association last year the writer was informed that any member of an American Automobile Association club would be accepted as a member of the A. G. A. on simple payment of fees.

Not Much Obtainable from A. C. F.

That august body, the Automobile Club of France, housed in a former abode of royalty, has less to offer the simple tourist than some of the more humble clubs. Its Touring Commission, however, has done and is doing useful work in the collection of information on tours, roads, foreign regulations, and custom duties. It is generally more concerned with improvements in general, improvements which benefit the mass of tourists, than in giving help to individuals. Recently, under the secretaryship of E. Andrieu, the work of the Touring Commission has been considerably extended and the publication of a weekly official journal on automobile matters has been undertaken.

The Motor Club of Belgium offers in its territory almost all the advantages given by the Touring Club of France. An understanding between the Belgium body and the A. A. A. gives reciprocal benefits between these two organizations.

NO CAUSE FOR ACTION, OWNER NOT IN CAR.

SEATTLE, WASH., April 8.—Owners of automobiles are not responsible for all acts of their chauffeurs, according to a decision handed down by Judge Griffin in the King County Superior Court. Suit was brought against James D. Hoge to recover \$8,200. During the progress of the trial it was shown that the driver was out for his own pleasure when the plaintiff was struck by the machine. Judge Griffin immediately took the case out of the hands of the jury and ordered dismissal of the action. Seattle automobile owners have had considerable trouble because of acts of their drivers. Contrary to orders they have taken surreptitious trips with friends. Carelessness often prevails during such trips. Owners here are now putting a stop to this.

LE GAULOIS TIRE WAGON ON ITS DAILY ROUND.

TIRE FIRM PREFERS MOTOR VEHICLE.

As illustrative of how tires are delivered and repairs collected in Paris, the accompanying illustration will be noted with interest. The tires are Le Gaulois, manufactured by Bergougnan & Co., a firm which has made enormous progress in recent years, and now has a large establishment close to the Avenue de la Grande-Armée. The truck is a Lacoste & Batemann fitted with Bergougnan solid tires. The headlights are of American manufacture.

ACCESSIBILITY IS A RENAULT FEATURE.

One of the most admired engines at the last Paris automobile Salon was the new four-cylinder Renault, an illustration of which is given herewith. A feature which must be apparent even to those little acquainted with the detail of engine construction is the accessibility and neat arrangement of the Renault motor. With the radiator carried behind the engine against the dashboard the maximum of accessibility is obtained, and water circulation piping considerably simplified; this principle first adopted by Renault three years ago is now being followed by several prominent French builders. Valves are all on one side, and are mechanically operated. The magneto is carried in front of the motor and is driven by gears off the camshaft, all of which are completely enclosed in the crankcase. It will be noticed also that the carbureter is carried on the right-hand side of the engine with induction pipe leading up between the two sets of cylinders and passing to the opposite side, where the inlet ports are centrally located between the exhaust ports. Engine control is entirely by throttle.

A MUCH ADMIRER CLEAN-CUT FRENCH MOTOR.

HOW ONE CONCERN HAS UTILIZED AUTOS.

Boston, April 8.—Starting in 1902 with four steam runabouts, the Moxie Nerve Food Company now has a score of cars, mostly gasoline, for the use of its salesmen, and also employs several big trucks for freighting purposes and a number of cars for new cross country advertising and inspection trips. More cars will be added this year, and one of the Moxie autos will do some valuable work in placing road signs over many of the country roads of New England. These signs will be distributed by special men, who will cover the territory in a 40-horsepower Matheson with a light delivery body.

As to where the automobile service saves, F. E. Thompson, the man whose far-sighted enthusiasm for the automobile is principally responsible for the Moxie Company's successful experiments, said to THE AUTOMOBILE correspondent the other day: "The cost of using the autos amounts in a year to about what it would cost to keep the same number of horse-rigs in our territory. But the autos cover the ground twice where the horses would get over it once. Our salesmen formerly kept closer to the railroads than now, and after they began using the autos they reached a good many small villages and cross-roads stores that had never done much business with us before. In the heavy business the trucks do work which horses could not be expected to attempt, because they make such long runs.

LAST YEAR'S MOXIE PARADE THAT STARTLED NEW ENGLAND.

But the Boston truck, which makes runs of reasonable city length, does the work of two two-horse vans."

Mr. Thompson himself knows how to get a good deal of enjoyment, as well as profit, out of automobiles. He has Stanley, Knox, Locomobile, Rambler and Matheson cars for his own use, and has made numerous tours. Counting business and pleasure, he has covered probably 50,000 miles by automobile since he became addicted to that kind of locomotion. Last winter he shipped his car to Florida, toured around Jacksonville for a time, then reshipped to Ormond and had his car on the beach at racing time. His experience has made him a good judge of the road building in various sections of the country. He says Massachusetts has by all odds the best system of highways; New Jersey is next, and Connecticut he places third. Southern roads, as a rule, he denominates bad, on account of lack of care and surplus of red clay. The roads between Schenectady and Rochester, in New York, come in for some pretty earnest condemnation from Mr. Thompson's lips. He thinks a big State like New York ought to do better.

TRACTION BLOCKS MOTOR 'BUS FRANCHISE.

PHILADELPHIA, PA., April 8.—The city of "brotherly love" wants the motor 'bus and the Auto Traction Company has been organized to fill the want. As yet it lacks a franchise and a bill granting it is now pending before the city council—at least it was until the last meeting of that august body, when it was finally referred back to the Highways Committee. It is thought that the blocking of the bill is a practical acknowledgment on the part of the local transit company that the motor 'bus is not looked upon with favor in that quarter.

SPRINGTIME ACTIVITIES WITH THE CLUBS

Worcester Club to Re-elect President Coughlin.

WORCESTER, MASS., April 8.—The annual nomination of officers for the ensuing year have been made by the Worcester Automobile Club. The nominations, which will go through unopposed next month, are: President, John P. Coughlin; vice-president, Daniel F. Gay; treasurer, William N. Stark; secretary, Frederick E. Frost. President Coughlin and Mr. Gay were appointed to secure a man to be known as assistant secretary, who will make his headquarters at the club and in reality be secretary. Mr. Frost finds that he cannot devote to the constantly increasing membership of the club and to his business the attention that each deserves, so Robert M. Pratt, a newspaper man, will become assistant secretary. He is well known in auto circles.

Worcester's automobile club is representative in every sense of the word. The club has roomy and comfortable quarters in the heart of the city, and a constantly increasing membership that now totals over 400. The policy of the club has been changed from a distinctly garage club so that now its activities include numerous social features, when the wives and daughters of members are admitted to the privileges of the club. It is affiliated with the Massachusetts State Association of the A. A. A.

The disposition of the club to make a campaign as a whole of educating the residents of the rural districts to the automobile all brought members into the fold, and with an increased membership it was possible to secure the entire top floor of the Chase building. The club this summer will have a roof garden.

The Worcester Automobile Club was organized February 16, 1901, when less than a dozen automobilists gathered at the agency for the Locomobile here and perfected an organization. J. W. Bigelow was president; B. A. Robinson, treasurer, and H. E. Shiland, secretary. From this time on the meetings of the club were of the happy-go-lucky sort, there being but little interest in the club manifested. In September of the following year the club held an annual meeting. George B. Cutting was then elected president; Dr. R. M. Gardfied, vice-president; H. E. Shiland, treasurer, and John S. Harrington, secretary.

The club then voted that its annual meeting should be held thereafter in May, and on the third of that month, the following year, Asa Goddard was elected president. From his election the club began to wake up. It was Mr. Goddard who thought and planned the hill climb of 1905. Unaided, practically, he managed the climb on Dead Horse Hill, overcoming the opposition of the civic authorities of Worcester, and, what was harder, the authorities in Leicester, who have jurisdiction over the greater part of the hill course. Before the first hill climb, Mr. Goddard managed and carried out successfully the Memorial Day meet of Greendale track.

Until November, 1904, the club held its meetings at any convenient office or clubroom, but during the month Mr. Goddard made arrangements to have the club headquarters at the Bay State Hotel. It may not be amiss to relate a story told among the members, which shows just how Mr. Goddard made arrangements that turned out for the best interests of the club. He arranged with the hotel management for the club to pay a certain reduced price, it is said, for its quarters. Anticipating the business that would fall to the hotel from visiting automobilists and club members, Mr. Goddard arranged that the club was to receive a certain percentage on all sales made in its rooms. It's easy to guess the result. In a very short time the club was not only getting its headquarters rent free, but the hotel management was owing the club money at the end of the month. The story may be a little overdrawn by continued repetition among automobilists, but in the main it is true.

Besides the hill climb, which is now an annual affair, the club holds an Orphans' parade annually, as well as a gymkhana at the Grafton club.

Ontario Motor League Formed by Canadians.

TORONTO, ONT., April 8.—At the annual meeting of the Toronto Automobile Club a very important step was taken in the formation of what will be known as the Ontario Motor League. With the organization of this body the corporate existence of the Toronto Automobile Club ceases, the club being taken over by the Ontario Motor League, in which all motorists in the province of Ontario are eligible for membership, and with which other local clubs will be affiliated.

The following officers were elected: President, Noel Marshall; vice-president, T. A. Russell; secretary-treasurer, E. M. Wilcox; directors, William Doble, R. J. Christie, M. C. Ellis, G. H. Gooderham, A. E. Chatterson, Dr. P. E. Doolittle, F. F. Miller, W. W. Doran and Lloyd Harris.

The principal object of the league is to promote a good roads movement throughout the province. Very tangible progress has already been made by the Toronto Automobile Club in offering a number of prizes aggregating \$1,000 for the best improved mile of roadway within a certain period to the various municipalities in the County of York. The roads in this country are greatly in need of improvement. The county has been backward in the past in spending money on them. Ten entries have been made and very considerable interest is being taken in the competition by the competing municipalities. The Ontario Motor League has taken over the work in connection with this competition and is taking steps to co-operate with other bodies in spreading the good roads movement throughout the province.

The following committees have been elected:

Good Roads: William Doble, chairman; F. F. Miller, E. J. Christie, Lloyd Harris, T. A. Russell, J. C. Eaton.

Membership: G. H. Gooderham, chairman; F. E. Mutton, W. W. Doran, A. E. Chatterson.

Legislation: M. C. Mills, chairman; T. A. Russell, G. H. Gooderham, Dr. P. E. Doolittle.

Publication: A. E. Chatterson, chairman; R. J. Christie, F. F. Miller, M. C. Ellis.

Rejuvenation of the Grand Rapids Club.

GRAND RAPIDS, MICH., April 8.—The Grand Rapids Automobile Club, at its recent meeting, elected thirteen new members, making the membership of the club now eighty-four. Considerable enthusiasm was aroused over club matters, especially a new clubhouse, and it looks as if the club, which has laid dormant for some time, intended to do something this summer. It is definitely settled that a clubhouse will be bought at Cascade, a delightful country place eight miles from the city, just a nice run for a dinner party on hot summer evenings.

Another matter which has been practically settled is the formation of a State Automobile Association for Michigan. The local club is in favor of it, and has appointed a committee to confer with the Detroit club at their next meeting, April 16. It is necessary, in order to have the association formed, for only three clubs to get together. If Detroit is not in favor of the proposition, it is believed that it will be an easy matter to get two other clubs, such as those at Muskegon and Kalamazoo, to join with the local club. So the association is practically assured.

J. R. Jackson, a Grand Rapids man, has just recently been appointed a member of the A. A. A. Touring Board.

Quaker City Club to Aid Members Unjustly Arrested.

PHILADELPHIA, April 8.—G. Douglas Bartlett, chairman of the law committee of the Quaker City Motor Club, has announced that his committee will defend, free of charge, all members of the club who think they have been unjustly dealt with by the police authorities of Philadelphia and adjoining counties in the matter of arrests and fines for alleged overspeeding or in mix-ups

over the tag question. This action was taken in view of the fact that many members, rather than suffer delays and incur additional expense for counsel fees, have been in the habit of meekly "ponying up" to the authorities, although convinced that they have been imposed upon. The ease with which some motorists "cough up," Mr. Bartlett claims, has a tendency to make the Vidocqs of the countryside all the more eager for easy money, with the result that what was at one time only an occasional nuisance is likely to develop into a constant menace to automobilists in general if something is not done to immediately check it. The bare announcement that such unjust arrests and finings will be fought to a finish will doubtless have the effect of making the village Sherlock Holmeses more circumspect.

Indiana Clubs Are Awakening.

INDIANAPOLIS, IND., April 8.—There are indications that a number of automobile clubs that were dormant last year will be rejuvenated this season. For some reason there was practically no interest in clubs through Indiana last year. On Saturday night a meeting was held at which plans were discussed for reviving the Indiana Automobile Club. At one time this was a prosperous organization with about 300 members. Later in the season an election of officers will be held. The president elected last year has not been located, as few of the members can recall who he was.

The Indiana Motor Club, which started an elaborate clubhouse at Broad Ripple last season, will endeavor to complete it this spring. Interest in the club will also be revived. Owners of Indianapolis and Terre Haute are planning to build a clubhouse midway between the two cities.

The interest in clubs at the present time is due largely to the fact that it is believed the A. A. A. tour will include Indianapolis in its schedule. An Indiana State body of the national organization seems to be assured.

Aero Club Entertains Wellman and Hersey.

NEW YORK, April 8.—Walter Wellman, the explorer who is planning to reach the North Pole with an airship, arrived in this country last week for a short visit. Wednesday night he was a guest of the Aero Club of America at its clubrooms, No. 12 East Forty-second street, and a fellow guest was Major Hersey, who with Frank Lahm won the Gordon Bennett balloon trophy for America. Mr. Wellman gave an extensive talk of a most sanguine sort in relation to his hope of traveling to the North Pole in his gigantic airship now being constructed in Paris. Major Hersey sailed Thursday morning last, in company with Dr. Fowler, another member of the expedition, and Mr. Wellman expects to return on the French line boat leaving this week. The party will leave Paris for Spitzbergen early in May, and the actual start for the Pole will be in the latter part of June.

Long Island A. C. Selects Route Across Brooklyn.

BROOKLYN, N. Y., April 8.—The Long Island Automobile Club has selected a direct route for automobilists driving from Brooklyn Bridge to Prospect Park. The telephone and telegraph companies have given permission for the use of their poles, and the signboards, two feet long by one foot wide, are now being placed by the Runs and Tours Committee, of which Alex Schwalbach is the chairman. The route from the Brooklyn Bridge plaza is up Liberty street, across Fulton, passing under the elevated railroad into Clinton street, then to Pacific street, turning left into Fourth avenue, and then left into Degraw street, which leads up to the Prospect Park Plaza.

Annual Dinner of the Peorians of Illinois.

PEORIA, ILL., April 8.—The Peoria Automobile Club gave its third annual dinner at the National Hotel. Sidney S. Gorham,

president of the Illinois State Automobile Association, was present and spoke on the new State automobile bill now before the Legislature. The dinner was well attended and prospects are good for club activity in Central Illinois during the coming season. The present officers of the club are: President, B. H. Onken; vice-president, A. E. Augerson; secretary, R. A. Whitney; treasurer, W. H. Rees; directors, J. B. Bartholomew, M. E. Ma-gruder, S. K. Hatfield, L. C. Wheeler.

Marylanders Will Have Tour to Jamestown Exposition.

BALTIMORE, April 8.—The Automobile Club of Maryland is planning a tour to the Jamestown Exposition this summer. While the plans for the run have not as yet been thoroughly completed, the prospects are that at the next meeting of the club the date for the tour will be determined and the final arrangements made. Howard W. Gill was in Norfolk and Richmond last week looking over the ground that will have to be covered. He reports that from Stanton to Baltimore there is excellent prospects for a comfortable run, but from Stanton on the roads would stagger a mule.

Entries Will be Plentiful for the New Jersey Run.

NEWARK, N. J., April 8.—Secretary Bonnell, of the New Jersey Automobile and Motor Club, is receiving numerous entries for the three-day endurance run, May 30-June 1. Morristown, German Valley, Washington, Somerville and Newark have been selected as controls for the first day. Thirty-three new members were elected at the last club meeting.

NEW CLUBS ADDED TO THE ROSTER.

Peoria, Ill.—The Pup-St. Louis Auto Club has been formed in this city with the following board of officers: President, Richard Lawrence; vice-president, J. R. Jobst; secretary, Charles Kolmenstetter; treasurer, R. M. Dunham.

Iowa Falls, Ia.—One of the first automobile clubs in this part of the State has been formed by automobilists residing in Wright county. J. Fitzmaurice, of Eagle Grove, is president and Eugene Schaffer fills the office of secretary.

Logansport, Ind.—An automobile club has been formed here to arrange for the reception of the Glidden tourists who will pass through the city shortly after the A. A. A. tour departs east from Chicago. The name of the new organization is the Logansport Automobile Club.

Atlanta, Ga.—The Automobile Country Club, with a membership limited to 100, is the latest addition to this city's representative organizations. Pending permanent organization, Edward H. Inman has been elected temporary president and Charles I. Ryan, secretary-treasurer.

St. Joseph, Mo.—Permanent organization of the St. Joseph Automobile Club has been effected with the following officers: President, Huston Wyeth; vice-president, Charles A. Kelly; secretary, Harry D. Todd; treasurer, E. A. Zimmerman. A miniature automobile wheel, in grass, has been adopted as the club emblem.

St. Louis, Mo.—The St. Louis County Automobile Club has been incorporated. Edward E. Doss, Ellisville, president; Peter Gluck, Gumbo, vice-president, and James Staebell, Manchester, secretary-treasurer. The club, which is composed of autoists in St. Louis county outside the city proper, will make a strong effort for improvement of the suburban roads.

Greenville, S. C.—A club is in process of formation here which will include all automobilists in the county. At the preliminary meeting Perry Beattie presided, and a committee was appointed to draw up a constitution and by-laws. Another committee was selected to nominate permanent officers for the permanent organization, which will be effected within the next ten days.

WAGNER READY FOR SICILY'S MOUNTAIN ROADS.

RADIA, ANOTHER CANDIDATE FOR THE TARGA FLORIO.

AUSTRIAN CLUB TO HOLD INTERNATIONAL RUN.

May 24, 25 and 26 the Austrian Automobile Club will hold an international contest for light touring cars over a circuit of 715 kilometers, starting and finishing at Vienna and passing through Leoben, Klagenfurt and Graz. Only stock cars using internal combustion motors will be eligible. They will be divided into three classes, as follows:

Class 1. Single-cylinder motors having a cylinder capacity not to exceed 1.5 liters.

Class 2. Two-cylinder motors having a cylinder capacity not to exceed 2.5 liters.

Class 3. Four-cylinder motors having an aggregate cylinder capacity not to exceed 2.6 liters.

Cars having two-cylinder motors with an aggregate cylinder capacity not to exceed 1.5 liters will be included in Class 1. All cars must carry regular equipment, be provided with two or more comfortable seats, mudguards, muffler, two brakes, three lamps and a regular touring body. Single-cylinder cars must carry two, twin-cylinder cars three, and four-cylinder cars four passengers or their equivalent in ballast. The run is to extend over three days and on each the "durchschnittsgeschwindigkeit," or mean speed, must be not less than 25 kilometers per hour for single-cylinder cars, 28 for two-cylinder cars, and 30 kilometers per hour for four-cylinder cars. A speed above 40 kilometers per hour is prohibited. The prizes will be awarded on a point system, figuring one point per minute whether overdue or too early in arriving at checking stations. Three minutes will be allowed in controls.

RECORD AUTO RUN FROM PARIS TO NICE.

PARIS, April 1.—Sorel, the Anglo-Saxon who converted Indian rajahs to automobiling, has set all Paris a-talking by a fast run to Nice on a 60-horsepower stripped touring car. He started from the capital at 2 o'clock in the morning, officially timed, and despite the darkness rushed along at an average of 35 to 40 miles an hour, guided by powerful headlights. Auxerre was reached at daybreak, Avallon, 140 miles from the capital, was rushed through at twenty minutes past 5, and Lyons was traversed at twenty-seven minutes past 9. Passing by way of Aix-en-Provence and Fréjus, the Casino at Nice was reached at seven minutes past 6, the entire distance of 611 miles having been covered in 16 hours 15 minutes. Deducting one hour and twenty minutes on the road for food and gasoline, the actual running time was 14.5 hours, and the average speed over 42 miles an hour. Sorel has broken all Paris to Nice records by this run.

HYDROPLANE BURNS AT MONACO MEET.

MONTE CARLO, April 9.—Excitement was caused here to-day when the ten kilometer hydroplane race was started. There were four competitors, *Nautilus*, *Motogodille*, *Glisseur*, and Comte de Lambert's boat with an aerial propeller. Just over the line the last named craft burst into flames owing to a broken feed pipe allowing the gasoline to escape. Attempts to put out the flames with water proved unsuccessful, and had not a committee boat rushed up with a patent fire extinguisher there would have been a disaster.

COMTE DE LAMBERT'S UNIQUE HYDROPLANE ON THE SEINE, PREPARING FOR THE MONACO RACES.

Balance of Trade Seen to Favor American Makers. Statistics can hardly be said to form reading of a wildly interesting nature, as a general rule, so that the message they convey is all too frequently lost on the man in the street. To him they are usually forbidding arrays of figures—meaningless except to those directly interested in their compilation. It is hardly necessary, however, to emphasize the vital significance of the message conveyed by a comparison of the import and export returns for the month of February of the present, as well as for the period of eight months preceding the latter, the detailed figures of which are given elsewhere in this issue. The fact that placing these totals together shows an excess of some \$165,000 in favor of the American builder means a great deal more than can be conveyed in a few words. It is not such a great while ago that there were no American automobiles at all, and for some time after that there was a period when there were no real automobiles built in this country—even their creators could not stretch natural pride in their own offspring to the extent of placing them in the same class as the foreign machines.

In the few years that have elapsed the whole face of things has been changed. The United States can boast of a greater number of automobiles in constant use than any other country in the world, and in consequence a greater annual output of machines. Judging from the steady upward trend of the American exports in this field, it will not be very long before a similar claim to supremacy may be established here also. The present showing means that in less than five years there has been created a vast American industry—so great that its surplus products are al-

ready to be found in every part of the globe in competition with those of French and German makers, who were already well experienced long before the American maker decided to take a hand. It means further that the value of the automobiles now sent abroad every month exceeds that of the foreign cars brought here, though the buying of the latter has increased enormously in the same period. There will be noticed a startling disparity between the number of cars which go to make up the valuation in each case—a fact that may be taken to indicate that the American maker caters largely to what foresight tells him will ultimately constitute the bulk of the demand—the popular-priced car.

Thorough Testing Out on a Safe Side the Industry. There is one thing that every well-established automobile builder in this country dreads—the specter of overproduction. That it stalks abroad most prominently when the industry as a whole finds itself at the opposite extreme—with well-filled order books, plants running full-handed and overtime in the attempt to keep up with the demand; is quite evident. It is from such conditions that overproduction is most apt to spring. The evil is one that has threatened the industry from time to time throughout the course of its existence—on occasion, seriously, but never less than at the present moment, and as long as present influences retain their power as controlling factors in this direction the danger could hardly be more remote and yet exist.

As an evidence of what is intended by influences in this respect, there may be cited the single illustration of the great pains taken by the makers of high-grade automobiles, not to mention the amount of time and money that are expended, that they may merely satisfy themselves that the cars are fully up to the high standard set, and that they may conscientiously say that nothing in reason has been left undone to make certain of the fact that the car is a perfectly built and perfect-running machine when it leaves their hands. If this alone were the only means taken, it would still remain a powerful factor—in reality it is but the culmination of an almost endless chain of inspections and tests through which every part of the car has passed. As long as every component that enters into the finished automobile is conscientiously inspected and tested and as long as the chassis is put through a trying-out process that thoroughly guarantees its integrity, there is little fear of overproduction—such methods are not consistent with an excess output.

Auto Publicity Exports Are Busy These Days. The constant repetition of a name in print is cumulative advertising that unquestionably results in making the public acquainted with the object so persistently referred to. Some of the publicity experts of automobiling, in their endeavors to bring forth something new and startling which will result in the appearance of the much desired name before the public, are hard put these days for inventing something which has not already been utilized and worn more or less threadbare. If these indefatigable seekers of attention succeed in whatever they undertake, none should begrudge them the results of their labor.

But the general public is beginning to discriminate between what might be designated as substantial publicity and that which is of the frothy sort. The automobile is asked to do all sorts of stunts, and some of these performances prove little and perhaps give an erroneous impression. For instance, of what actual value is it to quote but one instance, to be able to say that the motor of a car ran so many hours and so many days with the bonnet sealed up? Is it a guarantee to every one who buys a car of the same make that he can safely do likewise? Hardly. True it is that a motor which can perform its duty for continuous hours without attention of any sort has performed creditably, but at the same time simply because it may have had some trifling minor trouble, remedied in a few seconds, it should not be given a black mark and its efficiency questioned.

AUTO BILLS IN NEW YORK'S LAW MILL.

ALBANY, N. Y., April 8.—But three motor vehicle bills have been moving in the Legislature the past week, and one of them to which auto owners had no objections has become a law as Chapter 127, laws of 1907, by the Governor's signature. This was G. H. Whitney's bill relating to charge of tolls on bridges and toll roads. As it is a law, automobilists should be acquainted with its provisions. It provides that the owners of toll roads and bridges may collect from "every vehicle propelled by other than animal power, passing over the same, a toll rate not greater than the maximum rate allowed by law to be charged for the passage of vehicles drawn by two animals, provided that for such motor vehicles designed to carry only two persons the rate of toll shall not exceed the maximum rate allowed by law to be charged for the passage of a vehicle drawn over such a road or bridge, without a load, by a single animal."

Of the other two bills only one is actively moving and out of committee, and that is the Young auto-insurance bill. This is a perfected substitute copy of the bill which Mr. Young introduced and passed through the Assembly only to have it amended and finally stopped on third reading in the Senate to enable him and Senator Saxe to introduce the new substitute bill. The same idea of permitting the formation of companies to insure automobiles is involved, but this is the wording of the new section to cover it which is now said to be satisfactory: "against loss or damage to an automobile resulting from collision, and against loss by legal liability or damage to property resulting from collision of an automobile with another automobile, or vehicle, or object."

The Brough bill, amending the impounding and bail section of the present motor vehicle law, is reprinted as last changed and back in house committee on general laws, where it awaits an agreement between the introducer and President O. A. Quayle, of the New York State Automobile Association as to date of further hearing.

The latest freak bill introduced was that of Assemblyman Brooks, of Erie, which requires motor vehicles to be equipped with fenders when using the highways for the protection of life and limb of persons coming in contact with them. It has been referred to the general laws committee.

All other bills are resting in committees.

NEWS OF THE AERO CLUB OF AMERICA.

At the weekly Monday night session at the clubrooms, No. 12 East Forty-second street, New York City, Capt. T. T. Lovelace gave an illustrated lecture on Jamaica a few days after the earthquake. Some of the views were taken from a balloon.

Next Monday night A. M. Herring, a well-known aeronaut, will give a lecture on aeroplanes. Nikola Tesla is one of the speakers of the near future.

On the opening day of the Jamestown Exposition Capt. Lovelace, Alan R. Hawley and A. N. Chandler are to participate in a balloon race. On Saturday, at Philadelphia, Mr. Hawley, in the *Orient*, and Mr. Chandler, in the *Initial*, expect to make a joint ascension.

GLIDDEN CUP RULES TO REMAIN UNCHANGED.

Despite the fact that the Executive Committee of the N. A. A. M. at its session last week passed a resolution asking that the rules of the A. A. A. tour for the Glidden trophy be more or less modified and made less strenuous in character, the Executive Committee of the A. A. A. Touring Board will not make any changes in the rules as originally announced. Chairman F. B. Hower believes that the rules should result in a satisfactory contest, but if his committee finds a decided call for the addition of a runabout class a special cup may be offered for runabout entrants. A dozen or more have come forward and announced their intention to compete in the teams of A. A. A. clubs. It is predicted the list will exceed a hundred.

SUIT SUPPLIES SOME SELDEN STATISTICS.

On Monday and Tuesday of the present week the action in equity brought by the trustees in bankruptcy of the defunct Searchmont Automobile Company, of Philadelphia, Pa., against the Association of Licensed Automobile Manufacturers, was heard before Justice O'Gorman in Part VI, Special Term, of the Supreme Court, in New York City. The plaintiff contends that the association is a partnership, and as such, one thirty-first part of all profits made since the former Searchmont Automobile Company became a member in 1903 is due the latter, and accordingly constitutes one of its assets in bankruptcy. Prior to the hearing of the trial an order was granted by Justice Leventritt to inspect the books of the association and the report of an expert accountant thereon was placed in evidence.

It showed the income of the association during the period in question to have been some \$615,000 in round numbers, composed in part of \$82,500 in initiation fees and \$518,000 in royalties received under the Selden patent; its expenditures during the same period were \$228,342 for litigation and \$223,902 for administration, leaving a balance on hand of some \$163,000. The item for legal expenses was composed in part of \$114,100, for carrying on the action against the Ford company; \$15,350 for that against the Panhard company, and \$4,600 for the present action, all these figures only being carried down to December 31, 1906; they date back to March 15, 1903.

Among the witnesses called were E. H. Cutler, general manager of the association; Marcus I. Brock, assistant manager, and William S. Redding, of Redding, Kiddle & Greeley, patent attorneys, of counsel to the association. Mr. Brock testified that the association did not make a cent of profit from the 1906 show in the Garden, nor for that matter from any show it ever held. In that year between \$20,000 and \$30,000 was cleared, but it was all returned to the exhibitors in the shape of rebates.

During the course of Mr. Redding's testimony the fact was brought out that the Ford suit would come up for argument next Fall. All the rebuttal testimony is in and sixty days have been granted for the surrebuttal. The record now covers 6,000 pages. Asked the value of the Selden patent, Mr. Redding said it was impossible to state it, but denied having expressed the opinion that it was worth \$10,000,000. He was also examined at length regarding the formation of the Association Patents Company. The court granted an adjournment until Monday next for the preparation of briefs.

SECRETARY ELLIOTT'S WESTERN ROUNDUP.

Frederick H. Elliott, secretary of the A. A. A., this week is engaged in a Southern-Western trip which will have more or less to do with State associations in Maryland, Kentucky, Indiana and Missouri. President W. H. Hotchkiss is seeing to it that the national secretary is a busy man, but at the same time he is doing his share of the work. Tuesday night he was an invited guest at the annual meeting of the Pennsylvania Motor Federation at Pittsburg. Before the completion of his administration President Hotchkiss anticipates State bodies across the entire country.

During Secretary Elliott's Western trip there will be a conference at Indianapolis of Western manufacturers interested in the proposed stock car race to follow in October next the Vanderbilt cup event on the Long Island Motor Parkway.

BOSTON TO RETAIN MARCH SHOW DATES.

BOSTON, April 8.—Notwithstanding the fact that the other large shows will be held several months earlier than usual next season, the Boston Automobile Dealers' Association does not propose to change the date of its annual exhibition. At a meeting of the association a day or two ago the subject of an earlier show was discussed and it was decided to make no change, but to hold the 1908 show in the middle of March, as has been the custom for some years past.

COURT UPHOLDS THE OWNER'S RIGHT.

Automobile insurance is an institution of such recent inception that there has not been sufficient time for the courts to establish any precedents, so that any decisions in this connection are of interest to autoists generally. In two actions instituted by Veryl Preston against the *Ætna* Insurance Company and the Union Assurance Society, the Appellate Division of the Supreme Court in New York has upheld the right of the owner to recover under the long-established ruling in insurance litigation that where a provision in a policy is capable of being construed in two ways, that most favorable to the insured should be accepted.

Mr. Preston insured his machine in both of the above-named companies for one year, the *Ætna* policy covering "all direct loss or damage by fire except loss or damage caused by fire originating within the vehicle," while the Union policy also excepted "any loss or damage to the automobile or any of its parts or contents caused by fire originating in the automobile itself." While thus insured the machine was run into a ditch and upset by the chauffeur between Pleasure Bay and Monmouth, N. J. The gasoline ran out of the tank, spreading over the surface of the water and took fire from one of the kerosene lamps on the machine with the result that the machine was considerably damaged. Both companies contended that they were exempt under the clauses in question, and the referee before whom the matter was heard sustained them.

Justice Ingraham, of the Appellate Division, in reversing the referee and granting a new trial, says in part:

"The lamp was not within the vehicle but was outside it, nor was the gasoline that ignited and from which the fire originated within the vehicle. If the gasoline had not escaped from 'within' the vehicle, it is quite evident that there would have been no fire. The defendant company was responsible for any damage caused to the automobile, by reason of the burning of the gasoline, whether it was in the tank or had leaked from the tank, provided the fire did not originate 'within' the vehicle.

"It is settled that if a provision in a policy is susceptible of two constructions so that reasonable men on reading the contract would differ as to its meaning, that construction will be adopted which is most favorable to the insured.

"It seems to me that this fire was not within the exception, and that the plaintiff was entitled to recover."

EXPORTS BEGINNING TO OVERLAP IMPORTS.

There seems to be little doubt that long before the end of the present year the numbers and values of American cars exported and of foreign cars imported will have reached a point where the balance of trade will finally incline in the American maker's favor for the first time. That the culmination of the long uphill struggle against great odds is close at hand, is evident from the following figures. During the month of February of the present year there were 62 complete cars imported, valued at \$203,106, while during the same month there were 213 American cars exported, having a total valuation of \$386,309. This shows the substantial excess of \$165,203 of exports over imports, which is offset to some extent by the fact that during the period of eight months ending with February, 1907, there were 831 cars, valued at \$2,938,893, imported, while the valuation of the 1,582 cars sent out of the country was but \$2,471,859. It is only during the period in question that the value of American exports has reached a point so closely approximating that of the imports.

AUTO SCOOTERS TO REACH THE NORTH POLE.

No less than six automobiles, patterned after the euphoniously-named Long Island scooter, are said to be building for various Arctic explorers, who will use them in attempts to reach the Pole during the summer of 1908. Two of them are under construction for Dr. Frederick A. Cook, of Brooklyn, who once accompanied Peary, and a third is for Anthony Fiala, of Ziegler expedition fame, while the remainder are for other expeditions. Apparently no field is closed to the gasoline motor.

BOSTON-NEW YORK MOTORWAY SUBSIDIES.

BOSTON, April 8.—The scheme for an air-line highway exclusively for automobiles between this city and New York was given its quietus for the current year by the legislative committee on roads and bridges, which this week reported leave to withdraw on the bill for the incorporation of the company, which proposed to take land by right of eminent domain and build the double road highway at a cost of between \$12,500,000 and \$15,000,000. Just what particular arguments led the committee to decide against the bill are unknown, but at the hearing the committee men appeared to be suspicious that the bill was a disguised attempt to secure a railway right of way, and they were also somewhat skeptical of its financial soundness. Similar bills are pending in Rhode Island and Connecticut.

The action of the committee on roads and bridges on the highway bill is in line with its attitude toward all automobile legislation this year. Of the eight or nine measures brought before it, it has reported favorably on only one, and that is of minor importance, affecting only private roads. It still has under consideration the Governor's recommendation for an examining board for chauffeurs. The taxation committee still has under consideration the bill for an increase in the registration fees by means of a sliding scale based on horsepower.

TIRES WITH THE CAR ARE DUTIABLE.

WASHINGTON, D. C., April 8.—The Treasury Department has been advised of a decision of the Board of General Appraisers adverse to the importers in the case of the Auto Import Co., et al., against the Collector of Customs at New York. Complete automobiles "with tools and accessories," so-called, were the subject of the controversy. Duty was assessed on the cars as enterities at the rate of 45 per cent. ad valorem under the provisions of paragraph 193 of the existing tariff act, metal being the component material of chief value therein. The importers claimed that the tires, being made of rubber, were separately dutiable at 30 per cent. under paragraph 449. No objection was made to the assessment as made by the collector on the body of the automobile as distinguished from the chassis, although it was in chief value of wood, nor on the cushions, although they were in chief value of leather.

In its decision the Board stated that the claim set up by the importers was opposed to both reason and authority. "Just why the tires are not as much a part of the machines as the chain, gearing, the wheels, the brake, the seats, the wooden body, etc., has not been made clear to us," continued the Board. "The tires accompany each machine; are packed in the same case with it; they are of the particular size for and are intended to be used on it, and without them the machine would be practically useless."

MAINE LEGISLATURE ACTED WISELY.

PORTLAND, ME., April 8.—Judging from action taken by the Maine Legislature, the movement for good roads has received an impetus that will insure still further action along this most desirable line of improvement. The Legislature appropriated for the development of the highways of the State the sum of \$120,000. State Highway Commissioner Paul D. Sargent has been an earnest advocate of the good roads movement, and since assuming office, two years ago, has lost no opportunity of impressing upon the minds of the public the need of better highways for all vehicles as well as automobiles.

Maine automobilists are congratulating themselves upon the death of a very drastic measure introduced in the Legislature to regulate the speed of automobiles in cities and towns. This act was presented by representative Proctor, and provided that five miles an hour should be the maximum speed in cities and towns of the State unless those cities and towns otherwise direct. Through the efforts of Representative Walter J. Mayo the measure met its death in the House even after it had been favorably reported by the committee.

PITTSBURG'S SUCCESSFUL SHOW.

PITTSBURG, April 8.—The first automobile show in Pittsburg opened at the Duquesne Garden to-night with great eclat. Mayor George W. Guthrie pressed the electric button that started the big show and in the presence of over 2,000 people who were representatives of Pittsburg's army of 5,000 enthusiastic autoists. It was a brilliant assembly, and when the thousands of electric lights were turned on and the rare beauty of the gold and green setting brought out fully, Pittsburg had abundant reason to be proud of her show. Over \$400,000 is shown in the exhibits. Nearly thirty manufacturers are represented on the green baize floor, and in the gaily decorated booths there are complete lines of automobile accessories.

It was in 1899 that William N. Murray started the first automobile establishment in Pittsburg, and was roundly ridiculed by his business associates for making such a foolish venture in a hilly town. It is the pleasant irony of fate that Mr. Murray, now

would even suspect that there had been unwonted haste in getting the show proper together.

A fine musical program has been prepared for every evening of the week and special programs will be rendered Wednesday and Saturday afternoons. Another pleasant feature of the show is the speedway in Craig street, in front of the Garden.

BRITAIN'S ROYAL A. C. TO ASSIST TOURISTS.

From J. W. Orde, secretary of the Royal Automobile Club of Great Britain and Ireland, has come the following letter to Georges Dupuy, manager of the American Gold Cup Tour:

Georges Dupuy, Esq., New York City, U. S. A.

Dear Sir: I shall be pleased to give you every assistance possible in connection with the tour of American cars which you are organizing. There are no custom formalities in connection with cars entering England, but it is necessary to obtain licenses. If you will let me know how many cars and how many drivers there will be in the party, I will send you the necessary blank

DUQUESNE GARDEN'S AMPLE FLOOR IS THIS WEEK THE SCENE OF PITTSBURG'S AUTO SHOW.

president of the Standard Automobile Company, is the man who first conceived this show and has done his utmost from the start to make it a great success.

The show committee consists of W. H. LaFontaine, J. H. Cochran and Earl Kiser. The show is being given under the auspices of the Automobile Dealers' Association of Pittsburg, which comprises sixteen of the representative firms in this city. The proceeds of it will be turned into a fund of the association, with a view to further promoting the interests of automobiling in Greater Pittsburg in future times. It was contended by some dealers that the profits should be divided pro rata among the exhibitors, but this idea was ruled out at the end.

The show committee did not get possession of the Garden until Sunday noon, owing to the fact that a dog show had been held there the previous week. This made the task of getting the new floor, stands, booths, decorations and furnishment in order by 8 o'clock Monday night one almost herculean. It was accomplished by the dint of tremendous exertion, and many exhibits were not in place till late Monday afternoon. But when the fashionable assemblage gathered in the evening very few

application forms for licenses. I see no objection to the route which you propose following through England, but instead of crossing from Calais to Dover, I would strongly recommend you to cross from Boulogne to Folkestone, as the arrangements for shipping cars on the Boulogne route are much better than on the Calais route.

I should be pleased to extend to the members of your party the special club custom facilities, and I enclose a form by which you will see that all custom formalities in connection with the introduction of cars into France, Germany, Switzerland, Holland, Belgium, Italy, and Austria may be settled here before leaving. I enclose a couple of forms, which will show you what particulars of the cars are required and they also give the various amounts which have to be deposited for the different countries. You may depend upon me to do everything in my power to make your tour a success.

If you let me know the date of arrival in Havre, I will instruct the Club agent there to meet your party on arrival and to make arrangements for the issue of the necessary French licenses without delay. It will only be necessary to take over two unmounted photographs of each driver (head and shoulders only), measuring about 1 1/2 inches by 1 3/4 inches. The agent will attend to all details for you, but as there are so many it will probably facilitate matters if you let me know the make and horsepower of each car, the names of the owners, and the name of each driver.

Yours faithfully, J. W. ORDE,

London, England.

Secretary, Royal Automobile Club.

THE MAN WHO GAVE THE MARSH RIM ITS NAME.

It is frequently as much of a wonder how a thing happened to come by its name as how it came to be invented. This is the case of the Marsh quick detachable rim, which is about equally well known by that cognomen as by its other—the Diamond rim—

W. A. MARSH.

owing to the fact that it is owned and always has been controlled by the Diamond Rubber Company. In this case it took its name from its inventor, W. A. Marsh, of Columbus, O., whose portrait appears herewith, and it first received this appellation at the hands of its original makers, the Bryant Steel Wheel and Rim Company, of the same city. It is one of those little things that cause people who note its simplicity to marvel at the fact that no one thought of it long previously, and one with which, by the way, the inventor did well financially.

The demand for Diamond tires on the Marsh quick detachable rim has been unusually large since the beginning of the year and indicates that the call for easily dismounted tires will be a very important factor during the coming season.

BROKAW LETS SELDEN ACTION GO BY DEFAULT.

Attention is being called to the granting of a decree by Judge Chatfield, sitting in the United States District Court for the Eastern District of New York, awarding an injunction and an accounting of profits and damages, with costs, in favor of the Electric Vehicle Company, owners of the Selden patent No. 549,160, and stress is being laid on the fact that the defendant did not contest the action. Back in 1902 William Gould Brokaw bought a 14-horsepower Renault car, and, in common with many others, was promptly sued as an infringer of the patent. The majority of those who imported cars and were thus sued capitulated; Mr. Brokaw did not. In fact, he sold the car long ago—as far back as 1903—but the action remained on the calendar, and, in the fullness of time, it was reached. To contest it would have cost the defendant two or three times the original worth of the car, so that he permitted the suit to go by default and the Judge could not do otherwise than grant the plaintiff the entire relief demanded. As a result, Mr. Brokaw is forever enjoined from using the car he sold four years ago or importing or making any others, and must account for all profits and gains he made thereby, to which end B. Lincoln Benedict has been appointed master to take an accounting.

HOW AN AMERICAN MORS WAS UTILIZED.

From Camden to Atlantic City, N. J., the exact running distance is 58.3 miles, and through a driving rainstorm early on a recent Sunday morning a 40-52-horsepower American Mors carried two men and 1,000 pounds of Sunday newspapers in 69 minutes.

No accident marred the fast trip, which, however, attracted the attention of J. B. R. Smith, Commissioner of Motor Vehicles for New Jersey, and he took occasion to condemn the *New York Herald* for its violation of the speed laws of the State.

Recently there has been considerable discussion in several States as to the advisability of doing away entirely with speed limits and making the driver of an automobile or any other vehicle responsible for whatever damage might be caused no matter at what speed the vehicle might be traveling. It is the general impression that sooner or later legislation of this character will be universally adopted both here and abroad.

OLDSMOBILE MUDLARK ON 1,000-MILE NON STOP.

PHILADELPHIA, April 8.—Promptly at 9 o'clock, Saturday morning, the engine of the Oldsmobile "Mudlark," which came into the limelight when it successfully accomplished a trip from New York to Florida last winter, was cranked by William Folbarth, of the Oldsmobile factory at Lansing, Mich., and a few minutes later, with a bunch of local pressmen aboard, started up Broad street on what is intended to be a 1,000-mile non-stop run. It is hinted that if at the end of the scheduled distance the engine is running as well as expected the trial will be continued indefinitely. With O. W. Hoffman, T. W. Berger, John Taliss and Mr. Folbarth—all experienced drivers—to coddle the engine and keep it running, no trouble is anticipated in completing the 1,000 miles about Thursday morning. No attempt at speed will be made, and Manager G. Hilton Gantert, manager of the Motor Shop (which handles the Oldsmobile here), who is engineering the run, confidently expects the "Mudlark" to live up to its reputation should the expected April showers make the going heavy on the suburban roads.

BERKSHIRE COMPANY HAS BEEN REORGANIZED.

PITTSFIELD, MASS., April 8.—The Berkshire Automobile Company has been succeeded by the Berkshire Motor Car Company, the new concern having purchased the assets including plant, patent rights, finished cars, and shop equipment. The new company has just increased its present facilities 50 per cent. and installed the latest improved machinery to manufacture the well known Berkshire cars. The capitalization of the new concern is \$400,000, \$100,000 preferred and \$300,000 common stock, the new capital being secured by a bond issue of \$100,000 which is to be devoted to the development of the business.

The new company will build the 35-horsepower Berkshire model exclusively, the same chassis being fitted with either a runabout or touring body. H. D. Sisson has been elected treasurer and general manager of the new company, and a complete list of officers will be announced at an early date, as soon as the full details of the reorganization have been formulated and completed.

UNINJURED, BUT DEMOLISHED THE HOUSE.

A Rambler automobile was being tested on the factory track, when, in trying to pass another car by cutting inside, it struck an oil house standing on the edge of the track. The blow was so forcible that the machine swung round nearly ninety degrees, with disastrous results to the building. The remarkable feature was that as the force of the impact was taken by the left front wheel and the spring extension of the frame, the machine suffered no injury whatever. The experiment will not be repeated, for the Rambler people need their buildings.

WHERE THE RAMBLER BUTTED INTO THE OIL HOUSE.

BROAD PATENT ISSUED ON ELECTRIC VEHICLE.

With the issue of letters patent No. 845,105 on February 26 last to H. P. Maxim and the Electric Vehicle Company, there is strikingly recalled what may well be termed almost the entire span of life of the motor vehicle industry in this country, for the application for the patent was filed on May 26, 1899, a time when the electric was about the strongest factor in the field. The frames then in use extended from axle to axle and their length and design had to be changed for almost every slight variation of the chassis, so that every builder in the business was developing a great variety of frames and running-gear elements, a broad patent granted to A. L. Riker some time previous being considered to dominate the situation.

Mr. Maxim conceived the idea of employing a complete steering truck carrying the spring suspension, axle and wheels, and a second truck independent of the first, also embodying the same elements and adapted to have the motive power transmitted to it. By this arrangement it was possible to make the two elements in standard sizes adaptable to bodies of various types and sizes. This interchangeable system attracted considerable attention abroad and resulted in successful negotiations for its exclusive use by certain prominent builders on the Continent. Not a few of the original vehicles constructed on this principle are in use to-day. The patent just granted is very broad in its specifications.

SELLING AUTOMOBILES AT AUCTION.

The first auction sale conducted in New York City by the recently organized Automobile Auction Company of America was held last Tuesday, and, despite the storm, over 100 people were present. Several cars were sold, among them being an electric victoria in good condition, "knocked down" for \$125; a 1905 16-horsepower Clement-Bayard for \$1,150, and a 1904 24-horsepower Berg for \$910. The company conducting these auctions recently leased the entire building at 41-43 West Sixty-third street and announces its intention of conducting sales weekly. J. Hatfield Morton is the auctioneer. When the cars are offered their exact condition is stated, and the sales are made with the condition that the purchaser will have his deposit returned if the vehicle is not satisfactory. For two days previous to the sale the cars are demonstrated to possible purchasers. A similar company has been in existence in London for several years, and disposes of many cars annually. While there have been several automobile auctions held in New York City, this company is the first to organize the business on similar lines to those practised by legitimate firms in the horse and carriage trade.

LOGAN ADVANCES PRICES ON SEMI RACER.

Owing to advances in cost of labor and materials, as well as the fact that the design of the car has been developed far beyond the original estimates, the Logan Construction Company, Chillicothe, Ohio, have found it necessary to advance the price of their "Blue Streak Semi-Racing" type to \$1,750, the increase to become effective on May 1. The new price includes full equipment, consisting of top and lamps, but orders will be received up to May 1 at the old price of \$1,500 without top.

MAXWELL CARS MAKE SUCCESSFUL RUN.

In charge of H. A. Grant, of the Maxwell-Briscoe Company, the three cars of the latter made a most successful run from Trenton to Atlantic City, N. J., last week, using alcohol, kerosene and gasoline as their respective fuels. The official observers were H. de G. Robinson of the Automobile Club of America, and S. Y. Beach. It is expected that the official report of the run will be of considerable practical value.

IMPORTERS' JANUARY SHOW UP FOR SANCTION.

Following the steps already taken with a view to the holding of a show of imported cars later in the season, owing to the recent developments in the show situation, a sanction for a January date in Madison Square Garden has been applied for by the Importers' Automobile Salon, Inc., and was up for consideration by the Board of Managers of the Association of Licensed Automobile Manufacturers at its meeting on Tuesday last. The subject was referred to the show committee, to which the following members were elected: Colonel George Pope, Pope Manufacturing Company, chairman; Charles Clifton, George N. Pierce Company, and C. R. Mabley, Smith & Mabley, Inc. Charles Clifton, who is also the president of the association, succeeds Marcus I. Brock as member of the show committee. Mr. Brock was relieved of show duty at his request, owing to increased demands upon him as assistant general manager. The following companies were represented: Apperson Bros. Automobile Co., Sel-den Motor Vehicle Co., Buick Motor Co., Cadillac Motor Car Co., Electric Vehicle Co., H. H. Franklin Mfg. Co., Hewitt Motor Co., Knox Automobile Co., Locomobile Co. of America, Northern Motor Car Co., Olds Motor Works, Packard Motor Car Co., Peerless Motor Car Co., George N. Pierce Co., Pope Mfg. Co., Pope Motor Car Co., Royal Motor Car Co., Alden Sampson, 2d, Smith & Mabley, Inc., F. B. Stearns Co., Stevens-Duryea Co., Studebaker Automobile Co., Waltham Mfg. Co., Winton Motor Carriage Co.

A NEW JERSEY ROAD TO BEWARE OF.

Cortland Field Bishop, chairman of the A. C. A. Maps Committee, asks that public attention be called to the abominable condition of the highway between Rahway and Metuchen, N. Y. Owing to faulty construction and neglect, upheavals have occurred on the road and there are mounds at frequent intervals three feet high. Only a few days ago, while traveling over this stretch, the macadam gave way and Mr. Bishop's machine sank down on one side to such an extent that it was in danger of overturning. With the aid of a team it was over two hours before the automobilist could be extricated. A similar fate befel a large observation car.

FOUR DRAGONS FOR THE A. A. A. TOUR.

Official entrance of four Dragon cars has been made in the coming A. A. A. tour for the Glidden trophy. H. T. Branstetter, of the Chicago Automobile Club, and agent for the Dragon car in Chicago, is one of the entrants; John Kane Mills, of the Quaker City Motor Club, of Philadelphia, and president of the Dragon Automobile Company, is another, and A. L. Kull, of the New York Motor Club, and New York agent of the Dragon, is a third entrant. The name of the entrant of the fourth car has not yet been announced.

THREE STEARNS FOR THE A. A. A. TOUR.

F. B. Stearns, president of the automobile company of the same name, has written the Cleveland Automobile Club asking for the honor of representing it in the annual A. A. A. tour for the Glidden trophy. Mr. Stearns states that his company will enter as many machines as the club may designate, but not less than three, these to be driven by such well-known operators as Holden, Vaughan and Leland. The cars used will be the regular 30-60-horsepower 1907 type.

Montpelier, Vt.—The Pavilion Hotel livery stable at Montpelier, Vt., which has been closed for some months, has been leased by John J. Glinney, who will fit up the basement for an automobile garage. It will be opened for business about the first week in May.

SPARK COIL COMPANY TO QUIT PITTSFIELD.

A half interest in the Pittsfield Spark Coil Company has been obtained by Zenas Crane and Senator W. M. Crane. Concurrently with this news comes the announcement that the company will move from the present factory in Pittsfield, Mass., to the larger Crane factory at Dalton, Mass., recently vacated by the Dalton Shoe Company. A lease for five years has been obtained, with the privilege of buying the property at the expiration of that time. A much-needed gain in space will be made by the removal, which is expected to be terminated by July 1, the new factory having 33,600 square feet of floor space, compared with 11,000 square feet in the old building. William P. Wood, treasurer and manager, to whose well-directed efforts the company's marked success is due, will continue to look after its interests.

HOUPT ON VANDERBILT CUP REASONS.

"What bearing has the Vanderbilt Cup race on the selling end of the automobile industry?" is a question that is often asked. Harry S. Houpt, New York City agent for the Thomas, who entered one of the Thomas racers in the Vanderbilt last year, had this to say when the question was put to him:

"Prestige; that is the answer. It would redound to the good of the entire American industry. If I had merely been seeking advertisement last year I would have entered a stock car. But we are influenced by a stronger motive in contesting for the big prize. We want to win that cup from a sporting standpoint, and we know that unlimited benefit will come to the American industry as a whole if we do."

"THE WHITE HOUSE" OF L. I. PARKWAY.

The White Company, of Cleveland, through President Windsor T. White, has made formal application to A. R. Pardington for a plot of ground adjacent to the Long Island Motor Parkway. When the purchase is completed there will be erected on this plot a commodious headquarters for the use of owners of White steamers and their guests. The structure is to be called "The White House," and, as there are over a thousand White owners in Greater New York and vicinity, the building will be of no mean proportions.

THOMAS TO MAKE A HIGH POWERED RUNABOUT.

Within thirty days a new high-powered runabout will be placed on the market by the E. R. Thomas Motor Company, of Buffalo, N. Y. The most distinctive feature of the new model is a special motor of great power with four cylinders cast separately and a five bearing crankshaft. The price of this car is \$4,000.

NEXT SESSION A. L. A. M. MECHANICAL BRANCH.

At the next meeting of the Mechanical Branch of the Association of Licensed Automobile Manufacturers, to be held in New York, April 12, the subjects to be discussed will be self-starting devices, standardization of tires and rims, and alcohol as a fuel. These subjects have attracted the attention of the engineers of the branch for some time, and experiments and investigations regarding them have been under way. It is expected that some results of material value will be obtained and immediate action taken. The work of the committee appointed for standardization of tires and rims will be one of the most important accomplishments of the branch and in keeping with the standardization of bolts and screws and the adoption of uniform spark plugs.

ADDING TO THE AUTO INDUSTRY IN DETROIT.

DETROIT, MICH., April 8.—The Michigan Crucible Steel Castings Company, 248 Guoin street, this city, has been organized for the purpose of manufacturing crucible steel castings, and will make a specialty of catering particularly to the automobile trade. R. F. Flinterman, president and manager of the new concern, has recently severed his connection with the International Harvester Company, where for several years he has been in charge of its laboratories and foundry practice. Mr. McLeod, whose name is familiar to consumers of crucible steel castings, will have direct charge of the foundries. The company will be ready to produce castings by May 1.

PACKARD FACTORY CONTINUES TO ENLARGE.

Despite the great amount of enlargement that was designed and carried out during the past year at the Packard works at Detroit with a view to providing room for facilitating the handling of the 1907 output, the company has again undertaken building operations with the first sign of warm weather. Some idea of the extent of the plant may be gained from the accompanying photograph of it, which shows in addition the latest increase now in course of construction. This is to consist of a third story on the outside triangle that was built last summer. This is more than 950 feet long by 60 feet wide, and is of the same fireproof construction, using steel and concrete as the two lower floors. That the numerous additions planned and carried out during the past year or two have been a matter of wise foresight on the part of the Packard Motor Car Company, is evident from the fact that their tremendously increased facilities have made it possible to maintain deliveries well in advance of the schedule mapped out at the beginning of the season.

CAPACIOUS MANUFACTURING PLANT OF THE PACKARD MOTOR CAR COMPANY, AT DETROIT, MICH.

BRIEF ITEMS OF NEWS AND TRADE MISCELLANY

A two-story building is to be put up at 1452-1456 Michigan avenue, Chicago, for the Buick Motor Company.

An additional fifteen acres of land have been secured by the Buick Motor Company at Flint, Mich., to be used for experimental and testing purposes.

The Locomobile Company has had plans prepared for a four-story brick addition to be erected at its plant near Seaside Park, Bridgeport, Conn.

The interest taken by the king of England in all branches of automobiling is well known. In the matter of tires for his own cars, his majesty has ordered Continentals as the regular equipment.

The Phoenix Auto Supply Company, St. Louis, Mo., with A. L. Dyke as president, has increased its capital stock to \$12,000 fully paid in. A new catalogue has been issued by this firm which will be mailed on application.

A site has been purchased in the Black Rock district, Buffalo, N. Y., on which will be erected a \$30,000 plant for the Fedders Manufacturing Works, constructing square-tube radiators. The new premises will be occupied July 1.

The contract has been let for the erection of the big plant of the Maxwell-Briscoe Motor Company, at Newcastle, Ind., for \$150,000. The building will cover eight acres. Work will be commenced immediately and be continued night and day.

The Stackpole Battery Company, of St. Mary's, Pa., maker of the Elk Brand dry cells, is erecting a large addition to its already extensive plant. The improvement was necessary owing to the company's rapidly increasing trade. Night and day shifts have been working at the factory for some time.

Among the applications received for Truffault-Hartford shock absorbers, is one from Kenneth R. Otis, who had his four-cylinder Pierce Great Arrow equipped with the shock absorber last year, and has just written Mr. Hartford that he will have the six-cylinder Pierce Arrow equipped with a set of Hartford suspensions when he goes on the Glidden tour with it this year.

Although it has yet to celebrate its first anniversary, the E. R. Thomas Detroit company has found it necessary to make a material increase in the size of its plant. Recently a new testing barn was added and now plans have been accepted for two new buildings, while the details of a third are being considered. At the present time four Thomas Forty's are being turned out daily.

Georges Dupuy, manager of the American Gold Cup Tour, has received information from his Paris agent, John C. Hoveman, that the Mitchell Motor Car Company has entered a car in the tour to start from Havre. Mr. Sauerbach, manager of the Paris branch of the Mitchell Motor Car Company, has been very desirous all along that there be a Mitchell car in this tour. He has also proffered the use of a Mitchell to Mr. Dupuy for personal use while in Paris.

The factory and equipment of the Eishuth Horseless Vehicle Company, at

Middletown, Conn., have been sold at public auction by order of the United States Court in Bankruptcy. Everett J. Esselty, of New York, made the last bid of \$21,000, at which price he secured the property, subject to a mortgage of \$125,000. It is understood that the property was purchased for John W. Gates, of New York, and that business will be resumed and somewhat extended.

Traffic Manager Marvin, of the Association of Licensed Automobile Manufacturers, has just issued a warning to the members of the association regarding the shipment of automobiles. With the increasing shipments of automobiles coming on and the decreasing number of available and suitable freight cars, a situation is immediate that may result disastrously to some shippers. He strongly advises loading as many automobiles as possible in each freight car, if necessary, holding shipment until enough machines are ready to completely fill each car.

The historic Highland Park track at Detroit, Mich., will not be cut up into building lots, as was at first anticipated, at least not for the present. Instead, this summer will see some excellent racing at the former fort of the bangtails. The Ford Company has rented the grounds for the summer, and purposes to use the course for testing. The factory will hold a series of race meets for demonstrators each Saturday afternoon. The drivers will draw lots for cars, and percentages will be allowed according to the order of finishing. Records of the work of the drivers will be kept and at the end of the season cups and medals will be awarded the leading drivers.

In the business of automobile building as in many other lines, the progressive manufacturer usually has a choice of policies—he may devote all his energies to the building of a comparatively few high-priced cars, or to the turning out of a large number at a much lower figure. It seems somewhat of a coincidence that such a number of the members of the American Motor Manufacturers' Association should have chosen the latter policy on the basis that the ultimate demand would be for a comparatively low-priced car. Nearly all the small two-seated cars selling for \$1,200 or less—those that earned the original title of runabouts—are now made by members of this association.

The men who do the road testing of Thomas Flyers in and about Buffalo will be forced within the next few weeks to give up one of their favorite roadways. When the temperature begins to drop along the northern part of New York canalmen tie up their boats and go into winter quarters. As soon as they do the Thomas testers take to the tow path of the historic old Erie canal, where they may speed along to their hearts' content. This they have been doing all winter and the path has proven a good speedway. Now that spring is at hand the boat owners are beginning to end their hibernation period, traffic along the famous waterway is being resumed and the testers have been forced to take to the roads.

An illustration of how much work and expense is involved in combining simplicity and strength and reducing the

number of parts in the modern high-grade car, is found in a factory detail related by James Joyce, general manager of the American Locomotive Automobile Company. An interchangeable half-time shaft, having the cams integral with it, is a distinctive feature of the Berliet car. For making these accurately alike, so that each one will fit any car perfectly, machine work of great precision was required and this necessity called upon the resources of the locomotive concern for a new piece of machinery, which was duly created. By means of it, the shafts and cams are turned out from the solid steel bar, with a master cam compelling accuracy.

Someone counted up not long ago and found that there were sixty-four trades and professions represented in the work done on an automobile before it could be completed. At one of the factories in the country, however, that of the E. R. Thomas Motor Company at Buffalo, there is one which he did not include. It is that of interpreter. John Kruchten holds the position there, and he can write and speak English, German, French, Italian and Spanish. Most of Kruchten's work is concerned with the members of the foreign engineering department of the company. The men who compose this can all speak more or less English, but when technical matters come up and even the slightest mistake or misunderstanding must be carefully avoided, the interpreter has his work cut out for him.

RECENT TRADE REMOVALS.

The Uncas Specialty Company, of Norwich, Conn., has moved its New York office from 1555 to 1781 Broadway.

Leon Rubay, the well known importer of high-class sundries and ignition appliances, announces his removal from 140 West Thirty-eighth street to his new building, 1697 Broadway, New York City, between Fifty-third and Fifty-fourth streets.

NEW AGENCIES ESTABLISHED.

The Trident Tire Company, of New York City, has established a Philadelphia agency at 903 North Broad street.

New agencies have been established by the Wayne Automobile Company, of Detroit, Mich., as follows: Buffalo, J. A. Cramer, 737-741 Main street; Omaha, Bergers Automobile Company, 205 Farnam street.

A Wilkes-Barre sub-agency of the Ford Motor Company has been established through the efforts of A. A. Jones, of the Philadelphia branch house. The Pennsylvania Armature Works will handle the Ford in the Luzerne county metropolis.

The Atlas Motor Car Company, of Springfield, Mass., has placed the agency for the Atlas runabout with the Crane Automobile and Garage Company, of Providence, R. I., for that section. The Crane Company is building a fine new garage, which when completed will be one of the best in Rhode Island.

The Hercules Auto Specialty Manufacturing Company, of Los Angeles, Cal.

maker of the Hercules shock absorber, has established a Chicago office at 95 Dearborn street, and is having the Hercules manufactured in that city in large quantities by the Turner Brass Works. In the East the National Sales Corporation, 296 Broadway, New York City, is the factory agent.

The Electric Vehicle Company has closed its branch in Washington, D. C., which was conducted under the name of the Washington Electric Vehicle and Transportation Company. The Columbia agency has been placed with the Dupont Garage Company, which operates a large garage and salesroom at 2020-2030 M street, northwest. The garage in the Panorama building on Fifteenth street, formerly occupied by the Electric Vehicle Company's branch, will be used by the Dupont Company for its commercial business.

PERSONAL TRADE MENTION.

Mason B. McLaughlin, for some time connected with the selling force of the White Company's Philadelphia branch, will in the near future go to Cleveland as assistant to Vice-President Walter C. White.

General Sales Manager Charles B. Shanks, of the Winton Motor Carriage Company, accompanied by Mrs. Shanks, visited the company's branches in Boston, New York and Philadelphia this week.

Fred J. Pardee, of the Pardee-Canary Company, Chicago, has been appointed general sales manager of the St. Louis Car Company, of St. Louis, Mo., makers of the American Mors, vice George C. John, resigned. Mr. Pardee will resign as president of the Pardee-Canary Company, but will remain as a director in the concern, which handles the American Mors in Chicago.

G. C. Lewis, formerly of the Wayne Automobile Company of Boston, which last year represented the Wayne in the New England territory, is now at the head of the A. L. Kull Automobile Company, 1677 Broadway, New York agent for the Wayne and Dragon. Mr. Lewis is widely and popularly known in the trade, having been traveling representative for the Wayne prior to his Boston connection.

Benjamin Briscoe, chairman of the Committee of Management of the American Motor Car Manufacturers' Association, has gone to California for a rest and incidentally to look the field over

for a factory for Maxwell cars on the coast. He sailed last Thursday on the steamer *Proteus* for New Orleans and from there will go to Los Angeles, afterwards visiting San Francisco, Portland, Seattle and Salt Lake City. Mrs. Briscoe accompanies him.

Otis R. Cook has resigned his position as general western representative of the International Rubber Company, of Milltown, N. J., to accept the position of general representative of the Firestone Tire and Rubber Company, of Akron, O. Mr. Cook was connected with the B. F. Goodrich Rubber Company for twelve years, and went with the International people last August. He is one of the best known men in the tire selling trade, and one of the most experienced.

Not the least surprising of the recent name changes on the part of prominent personages in the trade, is that of Walter G. Morley, the announcement of whose resignation from the Aerocar Company, of Detroit, was hardly looked for. Mr. Morley has long been identified with the automobile industry, and though he is mum as to the new connection that has caused him to give up the secretaryship of the Detroit makers, it does not seem likely that he is now going outside of it. He has let it be known that he is to be even more prominently connected with another industry, but one intimately related to automobile building.

NEW TRADE PUBLICATIONS.

The Bay State Forty is a 40-horsepower touring car built by the Bay State Auto Company, of Boston, and embodying quite a number of distinctive features. A twelve-page booklet just published by its builders tells all about the new machine.

"Lozier Lessons" is the title of a small brochure issued by the Lozier Motor Company, Fifty-fifth street and Broadway, dealing in an interesting manner with the strong features of Lozier machines. Originality, easy driving, comfort, cleanliness, are a few of the twenty-two lessons that Lozier gives free to those who ask.

The 1907 catalogue of the Waltham Manufacturing Company, of Waltham, Mass., deals with a big line of models from 20-horsepower four-cylinder cars to small single-cylinder motors with friction drive. Each type is fully illustrated and described and sketches of the mechanical parts of the more important models are given. Pleasure as well as

light delivery vehicles are included in the catalogue.

Force-feed lubricators for automobiles and motor boats is the theme of the McCord & Co., Chicago, handbook. All standard types, each one designed with the view of meeting some particular requirement, but all embodying the principle of force feed by separate hydraulic pumps for each feed, working in unison, are fully described. Asbestos-lined gaskets, coiled-wire belting and McCord radiators are also dealt with in the well-produced handbook.

A MODEL BOSTON STORE.

E. L. Thompson, formerly of the Angier Company, has taken hold as manager of the Boston branch of the Post & Lester Company, whose headquarters are at Hartford, Conn. The new establishment, of which a

BOSTON STORE, 815 BOYLSTON STREET.

view of the exterior is pictured here, is centrally located in one of the busiest automobile districts of the Hub, and is one of the largest and best equipped accessory stores in that city. The interior is attractively finished in weathered oak, plate glass cases being employed to display the goods in a pleasing and effective manner. In addition to handling one of the most complete lines of accessories in New England, the company has secured the exclusive agency of the Continental tires, Splitdorf coils and a number of other well-known specialties. The store will be thrown open for business for the first time on April 12, and as Mr. Thompson has had considerable experience in the accessory line and is well known throughout New England, its success would seem to be immediate.

ONE DAY'S SHIPMENT OF THIRTY REOS, RECEIVED MARCH 30 BY R. M. OWEN & CO., NEW YORK.

INFORMATION FOR AUTO USERS.

The Schabinger Positive Gear Transmission.—Chas. H. Schabinger, Detroit, Mich., has produced a positive gear transmission which he claims will overcome the disadvantages of the different types of gearing now in general use. His invention relates to a sliding key transmission, with keys sliding in the slot of the main driving shaft; the ends of the keys are pinned to the shifting collar, which is moved backward and forward by the shifting fork; as the shifting col-

Louis, Mo. The engine is a 6-horsepower water-cooled single-cylinder two-cycle, 4 1-2 by 4 inches vertical. Transmission is of the friction type, the flywheel being faced with a composition metal disk 16 inches in diameter dressed on both sides. A 15-inch wheel works across the composition metal plate, contact being regulated by a ratchet foot lever. A hand lever shifts the contact wheel across the metal disk and any number of speeds may be obtained. Final drive is by means of a single roller chain from the countershaft to the rear axle. Ignition is by jump spark, the current being supplied by six dry cells. Three gallons of gasoline, enough for 60 or 80 miles, can be carried and the water tank and radiator hold about six gallons.

Gasoline Safety Devices.—The devices handled by the Non-Explosive Safety Naphtha Container Company, of 1133 Broadway, have a wide field of application and appeal very generally to automobilists. Among these devices may be mentioned a filler and safety cap for automobiles, which will prevent back draft and explosion when filling, also prevent incandescent flame from forming when a fire occurs with a tank filled

DETAILS OF SCHABINGER TRANSMISSION.

lar is moved along the driving shaft the free ends of the keys are forced into the double keyway of each driving gear wheel, by springs, thereby keying the loose gears on the driving shaft, causing power to be transmitted to the counter shaft, then back to the driving sleeve, which has a clutch formed on the power end. For direct drive the shifting collar is moved with the keys along the driving shaft until it meshes with the driving sleeve clutch, the free ends of the keys are then out of mesh with the gears, and rest on the inside of the thrust ring, allowing the gears to freely revolve. The inventor claims that this system will do away with stripping of teeth in changing speeds; in fact, change speeds may be made without releasing the clutch.

Light Weight Auto for Two People.—The A. B. C. machine is a construction of a very light two-passenger auto on the buggy principle, which will cost no

A. B. C. TWO-PASSENGER AUTO.

more than a horse and buggy, which will give much less trouble and which will travel over any road. The want is supplied by the Motor Vehicle Manufacturing Company, 1512 Locust street, St.

FILLER AND SAFETY CAP FOR AUTOS.

with the proper air and gas mixture for an explosion. It consists primarily of a safety cap and vent with a small ring of fusible metal which will melt at 200 degrees Fahrenheit, release the top plate and allow the gas to escape and burn on the outside of the container. The cap and diaphragms of gauge and perforated metal prevent the flame reaching the interior of the container, but allow the gas to pass out freely. An application of the same device is made to the tanks of automobiles in such a way that if a fire occurs the gasoline supply to the carbureter is shut off and the pressure released by the instantaneous opening of a safety valve. If the fire were allowed to continue it would burn itself out, but the tank would not explode. Applied to filler cans as used in garages, the safety device prevents any flame reaching the interior of the can; even should a light be applied to such a vessel it would burn harmlessly, and no flame would get inside to cause an explosion.

The "Cee More" Goggles.—The feature of these goggles is that they have curved amber lenses 1 1-2 by 3 1-8 curved at one end, square at the other, mounted in aluminum, fitted with leather trimmings. The amber glass is recommended by oculists on account of it

"CEE MORE" CURVED LENS GOGGLES.

being more restful to the eye than any other glass. The goggles are cool and comfortable, fit any face and give extra large vision. They fold up in small pocket case and are sent prepaid, with stick of anti-steam to prevent steaming of lenses. They are manufactured by the Bay State Goggle Company, 37 Prichard avenue, Somerville, Mass.

A New Non-Puncture Tire.—A glance at the cross-section cut of the Mitchell punctureless pneumatic tire, shown herewith, will clearly demonstrate the nature of this trouble-avoiding device. Attached to the felloe are a couple of steel flanges, holding within them an ordinary pneumatic tube. Secured to the end of the flanges is the outer shoe, the space between the tube and outer shoe being filled by a solid rubber leg or plug made in sections, each overlapping, presenting what is practically a continuous surface to the inner tube. The leg is held firmly in position by a metal clincher, through the sections of which it moves up and down freely, but without the slightest friction. With this construction the weight of a car coming or the tread of the outer casing forces the rubber leg upward, compressing the inner tube. The

CROSS SECTION MITCHELL TIRE.

air chamber being placed three inches under the outer shoe and protected on the sides by the deep metal flanges, can not be punctured. Inflation is effected in the ordinary way. The Mitchell punctureless pneumatic tire is manufactured by the Commonwealth Rubber Company, Reading, Mass. New York agents are Nash & Bartlett, 1001 Flatiron Building, New York.

An Article for the Ladies.—The Liscombe automobile veil is specially designed to protect the hat and hair from dust and the effects of the wind, while not unnecessarily obstructing the view or being heavy and cumbersome about the head. The veil passes over the hat, and attaches closely round the neck, thus

THE LISCOMBE AUTO VEIL.

the most elegant coiffure remains undisturbed even after a long automobile ride in an open car. These veils are made to order in all shades of silks and chiffons to match automobile cloaks and costumes by Lucia E. Liscombe, 119 Massachusetts avenue, Boston, Mass.

New Form of Shock Absorber.—Whether they are called shock absorbers, suspensions, anti-jolts, or anything else, the benefits derived from some form of spring check between the body and axle of the automobile are undoubted, and, as a result, these appliances are being improved constantly and new forms are making appearance.

The accompanying illustration shows a new arrangement combining both springs and friction disks. Frictional re-

plunger moving up and down in the casing after the manner of a piston, while the rod works through a guide like a piston rod. Above and below the plunger are helical springs, which offer resistance to the movement of the plunger in both directions.

When attached to a car the action of the device is as follows: The springs are of such strength that they allow the car to rise and fall somewhat on its own springs, and consequently the plunger works up and down in its casing, without oscillating the friction disks with relation to each other. This allows the car springs to play as freely as is necessary on smooth roads. When rough roads are encountered, however, the motion of the car springs will be so great as to compress the check springs to such an extent that the friction disks will oscillate upon each other and check the tendency of the car springs to compress or recoil with abnormal violence. All parts of the device, with the exception of the connecting link, the spring steel washer and the helical springs, are of bronze. It is made by the Hercules Auto Specialty Mfg. Co., of Los Angeles, Cal.

Bullard Speedometers.—Nothing to lubricate about it and no adjustments of any kind necessary are two of the important features of the Bullard instruments. They are constructed on the same principles as

the governors used on high-speed engines for electric lighting where uniform speed and steadiness are of vital importance. At the maximum speed the power exerted by the weights amounts to six pounds, thus holding the pointer firm and making the instruments "dead beat" at every division of the scale. Another advantage is the comparatively low speed of the flexible shaft which turns less than twice as fast as the wheel. The complete speedometer comprises a minimum of parts and can be attached to either front wheel by a universal front bracket that fits any car, the wheel gear and flexible shaft also being readily put in place, a simple and effective form of universal joint being employed. It is enclosed in a heavy bronze case and is designed to stand continuous usage, all the moving parts being made of brass or other non-corrosive material, besides which it is made water and dust-proof. The Bullard speedometers are made by J. H. Bullard, Springfield, Mass.

Drop Forged Crankshafts.—"More than forty of the largest motor and motor car builders are using our cranks with entire satisfaction." is a statement that speaks for itself and scarcely calls for comment. It is embodied in a leaflet sent out by the Wyman & Gordon Com-

pany, of Worcester, Mass., and Cleveland, O., illustrating some of the numerous styles of single and multiple throw crankshafts that they have special facilities for turning out in quantities. All stock cranks are made from special steel adapted particularly for the purpose and are subjected to a special process of heat treatment.

New Detachable Tire Grip.—The makers of the Healy leather tire have just put on the market a new detachable tire grip, made of a very tough, water-proof chrome leather. As will be seen by the accompanying illustration of it.

NEW HEALY DETACHABLE TIRE GRIP.

there are comparatively few cross straps connected at each end to side straps which serve to hold them in place on the tire. These cross straps have steel rivets inserted in them and are fastened to the side straps by a simple and ingenious device which allows any part to be instantly replaced when worn out. Owing to the softness and pliability of the leather bands, the grips do not injure the tire and may be tightened by means of a strap and buckle which makes them silent running. They prevent skidding and do not throw mud on account of their close contact with the tire itself. They are made by the Healy Leather Tire Company, 88-90 Gold street, New York City.

Eagleine "No-Karbon" Cylinder Oil.—If it could be figured out exactly what percentage of trouble is caused by each accessory to the car, there is little, if any, doubt that prominent at the head of the list would come the item of "poor lubricating oil" as a prolific source of worryment. Here, if nowhere else on the car, should be penny wise and pound foolish policy that would skimp by saving a few cents per gallon on lubricating oil be repressed, for of few other things can it be said so truly that the very best is none too good. That bugbear of every autoist—soot—is the direct outcome of poor oil and the trouble caused by its accumulation is endless. The Eagle Oil and Supply Company, 104 Broad street, Boston, Mass., claim that in their "No-Carbon" oils they have a cylinder oil which not only has a high lubricating value, but positively will not become deposited in the shape of soot.

sistance to the movements of the springs is offered by a pair of conical plates between, with a correspondingly double concave plate clamped between them; these parts are held in constant contact by a six-armed spring washer, the tension of which is regulated by a nut.

Wear is automatically taken up by the cones advancing into their recesses in the central plate. The central plate is integral with the lever, and on the opposite end is the spring rigging, as the illustration shows. The friction end of the device is attached to the frame of the car and the opposite end to the axle by means of the clamp on the end of the rod.

The casing is pivoted to the small end of the lever, and inside the casing is a small plunger attached to the rod, the

THE AUTOMOBILE

THOUGH of exceeding interest as a whole, it is doubtless in the elaborate provision made for storing and handling cars that the attention of the autoist and club member will be centered in the new building of the Automobile Club of America, which is located on Fifty-fourth street between Broadway and Eighth avenue, New York City. True, no effort has been spared to make the club and social features prominent, and every facility known to the up-to-date establishment of the kind has been provided, but then there are many elaborate clubhouses in the metropolis, and but one that is at the same time a club and a garage. It is hardly necessary to state that in designing the arrangements for both housing and taking care of the cars nothing was left to chance or experiment. Every system extant prior to the time the building was started was studied and advantage taken of the knowledge gained to avoid errors.

Starting at the ground floor, there is a large entrance for the cars, and a similar exit, at each of which there is stationed a checker who records the movements of every car kept in the building. These two entrances are situated between the members' entrance at the Broadway end and the employees' entrance at the opposite extreme. Passing through the entrance for cars one finds himself in a spacious room with a capacity of 50 to 70 cars and which is intended principally for temporary storage; that is, cars in use which are to go out again shortly. There is a washing stand on this floor, also a turntable facing the two huge electric elevators, so that the cars may be run on the latter according to the direction it is desired they should face when coming off on the upper floors.

The street floor also contains a large members' locker room and the office of the superintendent of the building.

Gasoline and Oil Used on But Two Floors.

Though every portion of the construction of the building is fire-proof, barring the wood trim in the social end of it, neither gasoline nor oil will be handled except on the street floor and the top floor which houses the repair shop. They have been finished with a special hard-glazed material which, beside being fireproof, is also said to absolutely resist oils and gasoline. Fuel storage is provided for in the sidewalk vaults in the shape of a number of small tanks in order to comply with the regulations of the Bureau of Combustibles. They are filled by pipes terminating at the curb line, cars being replenished on the street floor by measuring pumps delivering exactly a gallon per stroke. The elevators, which have a platform measuring 10 by 18 feet, are also floored with same non-absorbent glazed material and have iron sides. Automatically locking gates are provided, the control preventing the gate from being opened except when the elevator is in place and also preventing the latter from starting until the gate is closed.

Four entire floors are devoted to the storage of cars and provision has been made on each for the use of movable iron partitions for those of the club members who wish to keep their cars in locked "stalls." The roof has been designed to bear the weight of a number of cars and the elevators run to this level, so that in case of emergency it can be utilized temporarily for storage purposes. Both the elevators and the

ONE OF THE HUGE ELECTRIC ELEVATORS.

MAIN ENTRANCE TO THE NEW CLUB HOUSE.

stairways are separated from the remainder of the building by a substantial fire wall and automatic metal doors on each floor.

Complete Modern Repair Shop.

As the building is designed to house several hundred cars permanently, it is only natural that most complete facilities for taking care of every kind of repairing have been installed. As already mentioned, the repair shop is located on the top floor, which is entirely given over to it. Here will be placed a complete outfit of electrically driven machine tools, the department being in charge of an expert worker under whose supervision all machine work will be done. This part of the shop is separated from the remainder of the floor by a wire partition. In this open space chauffeurs may dismount and repair their cars, passing all parts requiring machine work through a wicket to the latter department, to which they will not be admitted. To a very large extent the front and rear walls of each floor are composed of fireproof wire glass windows, and this is particularly true of the repair shop, which is lighted by a skylight in addition.

The club's dynamometer will also be installed on this floor with every facility for measuring the output, efficiency and fuel consumption of any make of car, beside conducting other tests of an interesting nature. A great deal of attention has been devoted to this feature by the Technical Committee of the club and it is expected to be of considerable interest not alone to members, but to autoists generally, as it is planned to do considerable testing work here. The building is to have its own lighting service, turbo-generator sets being employed to generate the current with accumulators both as an emergency, as no provision has been made for the use of illuminating gas in the building, and to carry the entire load when not much current is needed.

Construction of the Building.

As will be evident from the photograph illustrating the façade of the building, no attempt has been made at ornamentation above the main or clubroom floor, general utility and adequate lighting having been the aim rather than architectural features. The construction in general is of reinforced concrete, and every effort has been made to render the building fireproof throughout. With a view to preventing the rapid spread of a fire in case it should originate on one of the storage floors, all the columns are provided with hooks from which will depend round-bottomed buckets of sand in addition to the usual chemical fire extinguishers. A number of these columns are also wired to the electric lighting service and have counter-sunk attachment receptacles for the convenient connection of hand lights and flexible cords to render inspection of the cars easy.

The building is eight stories high and the materials used in its construction are marble, Indiana limestone, white brick and terra-cotta, the latter being employed in two colors for the ornamentation over the window arches on the main floor.

COLGATE HOYT,
President of A. C. A.

Social Features Have Not Been Sacrificed.

Though such painstaking attention has been devoted to the housing of the cars and such a tremendous amount of space is given over to them, the purely social end of the club has not been overlooked by any means. The main entrance at the Broadway end of the building opens into a corridor twenty-five feet wide, terminating in a grand staircase leading to the second floor. Under the landing of this stairway is located a ladies' waiting room, lighted by a large dome skylight; it is provided with all conveniences and elaborately furnished. At the head of these stairs is the main assembly room rising through two floors. It is finished in the Renaissance style with a beam ceiling patterned after that of the famous chateau of Cheverney. This room is separated from the grill room, which is capable of seating 300 people, by six sliding doors, so that the two may be thrown together. Adjoining the grill is the governors' room, and beyond that the bar, serving room and kitchen, each of which is fitted with modern appliances throughout. A mezzanine floor accommodates the secretary's office and a billiard room, the remainder of it being given over to garage space. On each of the storage floors there is a special room for chauffeurs. Though the new

TOURING BOARD'S ELABORATE MAP SYSTEM.

ONE OF THE FOUR GARAGE FLOORS WITH THEIR MANY WINDOWS.

club building has actually been in service for the past week or two, it was not formally opened until to-day, the 18th inst.

In view of the tremendous growth of the Automobile Club of America, a brief résumé of its history will be of interest. As the result of a conference between two autoists, Whitney Lyon and George F. Chamberlain, a call for a public meeting at the Waldorf on June 7, 1899, was published generally. The call for the meeting contained the following statement:

"In view of the rapidly increasing number of self-propelled pleasure vehicles in this country and the widespread interest in the subject, and the almost certain use of the automobile as a form of sport in the United States and the difficulty of procuring proper storage and care for the vehicles, it has been thought desirable to call this meeting of owners or intended owners for a conference looking towards the formation of a club."

At this meeting George F. Chamberlain was elected chairman and Capt. Homer W. Hedge secretary. Mr. Lyon briefly ex-

plained the purposes of the meeting and the intense opposition and hostility to the automobile which was being everywhere

shown. There were about thirty present at this meeting. A committee was elected to draft a constitution and by-laws. On August 16, 1899, a charter was procured under New York laws and the club duly incorporated. At the meeting held on October 16, 1899, a constitution and by-laws were adopted, and the following were chosen officers: Acting-president, George F. Chamberlain; treasurer, V. Everitt Macy; secretary, Homer W. Hedge. Official recognition as the national automobile club of America was promptly received from the clubs of Great Britain and France.

SECY BUTLER, TO WHOM THE CLUB OWES MUCH.

Temporary quarters were engaged at the Waldorf and the real work of the club commenced. The purposes and objects of the club are set forth in the charter and are as follows:

The objects of this corporation are the promotion of a social organization or club composed in whole or in part of persons owning

THE MAIN ASSEMBLY HALL, DESIGNED AFTER A FAMOUS FRENCH CHATEAU.

THE LADIES' ROOM UNDER THE STAIRCASE.

self-propelled pleasure vehicles for personal or private use. To afford a means of recording the experience of members and others using motor vehicles or automobiles. To promote original investigation in and development of motor carriages. To co-operate in securing rational legislation and the formation of proper rules and regulations governing the use of automobiles in city and country and to protect the interests of owners and users of automobiles against unjust or unreasonable legislation and to maintain the lawful rights and privileges of owners and users of all self-propelled pleasure vehicles. The encouragement and development in this country of the automobile. To promote and encourage in all ways the construction and maintenance of good roads and the improvement of existing highways, etc.

November 4, 1899, was a famous day in the annals of the club, for then occurred the first public parade of automobiles ever held in the United States. Thousands of spectators blocked Fifth avenue when thirty-four cars, headed by a band, started for Riverside Drive. The line of the route was thronged; the course turned west at 110th street and a few were unable to ascend the grade and dropped out.

The next club run took place January 27, 1900, and was to Kingsland Point, north of Tarrytown. Ten automobiles propelled by steam and three by gasoline made the start; eight in all survived.

The first annual banquet of the club was held at the Waldorf April 2, 1900, about 100 members being present, and addresses were made by Major-General Nelson A. Miles, ex-Mayor W. L. Strong and others.

The first road race promoted by the club took place on Long Island over a course of 50 miles on April 14, 1900. There were ten entries for a cup presented by Leonce Blanchet, of the Automobile Club of France. The race was won by A. L. Riker in a

THE GRILL ROOM, WHICH ACCOMMODATES 300 PEOPLE.

specialty constructed electric in 2:30. The first long-distance race was from New York to Philadelphia, June 2, 1900; 20 cars took part and 16 finished. The start was made from New York at 7:30 A. M., stopping at Princeton, N. J., for lunch; the first car reached Philadelphia at 7:20 P. M., the distance being 117 miles.

Albert R. Shattuck was elected president at the first annual meeting held October 20, 1900, the club then having a membership of 260. The years 1901, 1902 and 1903 were periods of great activity in club affairs. On November 17, 1903, 454 members were enrolled.

The first annual exhibition was held in the Garden on November 3, 1900, with 66 exhibitors, increasing to 176 cars in 1901, 227 in 1903, 258 in 1904, and 290 in 1905, all these shows being held in the same place. In 1906, on January 13, the sixth annual show was held in the 69th Regiment Armory, but as makers were limited to one type of car, only 247 were exhibited.

On September 9, 1901, there was held the first long-endurance run, over a course of 500 miles from New York to Buffalo. Eighty cars started and 44 reached Rochester September 13, when the test was abandoned by reason of the assassination of President McKinley. May 13, 1902, a 100-mile non-stop run was held from New York to Southport, Conn. Fifty-five cars started, 44 finished and 28 made an absolute non-stop run. October 9-15, 1903, a reliability contest was held from New York to Boston and return,

A CORNER OF THE MEMBERS' BILLIARD ROOM.

a distance of 490 miles; 75 cars started October 9 and 68 finished in New York, October 15, within the time limit. May 20-21, 1903, the first commercial vehicle contest took place over 40 miles of city streets. The first day 11 vehicles started and 9 finished; the second 9 started and 7 finished.

On the retirement of Mr. Shattuck in 1903 Winthrop E. Scarrit was unanimously elected; in 1904 the club had 589 members. Dave H. Morris succeeded Mr. Scarrit as president. The club's membership in 1905 was 1,079, and is now over 1,250. In May, 1905, it was resolved to build the clubhouse. The building committee consisted of Colgate Hoyt, chairman; Dr. Schuyler S. Wheeler, and A. R. Shattuck. The land was purchased the same month for \$210,000 and the building cost about \$350,000.

Starting a little more than a year ago, the club established a touring bureau, and after considerable search for a man able to fill the unusual requirements, it was placed in charge of A. L. Westgard, than whom few are better fitted for the post, as he has probably made more road maps than any other man in the country. About \$5,000 was expended in the organization of the bureau, and it is expected that \$5,000 to \$7,000 will be appropriated each year to carry it on. Up to date fifteen special maps have been published, covering New Jersey, Long Island, the Hudson river district, Connecticut, Massachusetts and upper New York State, besides an index to the maps and route cards. Supplementing these, Mr. Westgard has gathered a comprehensive collection of foreign touring maps.

TO the many autoists who are contemplating a visit to the Jamestown Exposition it will be welcome news that there is a practical touring route of but 340 miles between New York and Norfolk. By "practical" I mean not that there is a fine macadam road all the way, but that the route is of such a character that a sturdy touring car should be able to negotiate the trip without difficulty. Recently, while looking into the railroad routes to Norfolk, I noted that by far the shortest was by way of Philadelphia, Wilmington, and Dover, Del., and thence through the "Eastern Shore counties" of Maryland and East Virginia to Cape Charles, from which point the balance of the trip to Norfolk is made by boat. It occurred to me that it would be entirely practical to go this way by automobile, and, finding no information on this route in touring literature, I determined to go and find out. Then I could tell the crowd how to go.

From New York our first day's trip was to Philadelphia, following the beaten touring route by way of Staten Island, New Brunswick, Trenton, and Burlington. Leaving Philadelphia, the next day, by way of South Broad street, we followed the trolley line to Chester over an excellent macadam road which is built over the marshes. From Chester we found a very fair road to Wilmington, Del., the last few miles being over a toll road. Wilmington is twenty-nine miles from Philadelphia, and, throughout this distance, the road skirts quite closely the Delaware River. Leaving Wilmington we were in practically unknown country. We were confident that, whatever might be the condition of the roads, our White steamer would carry us to the destination, but we were by no means sure that the tour would be such that we could recommend it. The event proved, however, that the trip from Philadelphia to Cape Charles may readily be made in three days, and if a man cares more for speed than for scenery this might be reduced to two days. But 'tis better to take time and enjoy yourself.

We had not gone far from Wilmington when we encountered a type of road which prevails the greater part of the route, namely, heavy sand of a kind which does not pack in any kind of weather, no matter how heavy the traffic may be. The farmers' buggies and wagons, all traveling in one track, have worn deep ruts in the roads, but if these are "straddled" the road can be covered at a very fair average speed. The ruts wind aimlessly from one side of the road to the other, and the man at the wheel has his work cut out for him, and, sometimes, 'tis hard, too.

The country is absolutely flat, and yet is by no means monoto-

nous. About twenty miles south of Wilmington we had a genuine scenic surprise, where the road crosses the Chesapeake and Delaware canal. The high banks of the canal rise precipitously from the narrow strip of water which flows lazily on its way from Chesapeake Bay to Delaware Bay. The accompanying photograph better than paragraphs of description conveys an idea of this interesting spot.

We did not need to be told that the automobile was still a novelty all through that region—the action of the horses convinced us that few machines had been there before us. Fortunately, in that part of the country there are practically no fences. The fields are cultivated right up to the edges of the road, just as they are in France. Accordingly, when a horseman would see us approach he would drive off the road into the fields, and, when we had passed, "turn around and drive right back again." We had many such incidents.

Practically all of Delaware is under cultivation, and, as this is the season of the year for plowing and sowing, we saw agricultural activity on every side. Although winter had not yet spent its force in New York, we saw many orchards of peach trees in blossom and the meadows were a verdant green.

When we got south of Dover we encountered a condition which reminded me strongly of some of the Western States. The highway was no longer straight or approximately so, but would occasionally turn east for a mile or so, then abruptly turn south again, and then, for no apparent reason, lead due west for a while. Thus we covered a considerably greater distance than do the crows on their way north and south. In general, we could take our directions from the telegraph wires; but even this guide sometimes failed us, for the wires often leave the main highway to enter some town several miles to the east or the west. Occasional inquiry from the inhabitants is a safe plan.

When approaching Seaford, the largest town in southern Delaware, we came to a 12-mile stretch of shell road. Further south we encountered this same style of road, at intervals which were all too rare, but sufficient to give us an opportunity to learn the advantages of this type of road construction. The shell road is absolutely smooth, drains readily, gives very good traction, and is comparatively dustless. The shell road is very easy to build, and we thought what a world of benefit a vigorous good roads campaign might be for the State. To make a shell road all that is necessary is to dump the shells on the road bed, distribute them evenly

WHERE WATER OVERFLOWED THE ROAD AT CHESTER, PA.

WE STOPPED TO GIVE A GREEN HORSE A LOOK.

YOUNG AMERICA AND SCHOOLHOUSE, LAUREL, DEL.

to the depth of a few inches—and the traffic nicely does the rest.

There is an inexhaustible supply of the raw material for shell roads right at hand. Chesapeake Bay is the natural habitat of the oyster and the vast oyster canning factories, which have long comprised one of the principal industries of the region, turn out the shells by the million as a by-product. We wondered why every mile of road on the peninsula was not covered with shells long ago, until we learned that the shells are in demand to be turned into lime for use as a fertilizer.

We spent the night at Seaford, 115 miles from Philadelphia, and although we fared quite well at the Sussex Hotel there, we later learned that a better schedule, as regards the first night's stopping place, was possible and more convenient.

The next morning we again had a few miles of shell road, but this did not last long, and we were soon plowing through the sand once more. Fifteen miles out we passed near the town of Delmar, which, as the name suggests, is on the border between the States of Delaware and Maryland. Here we buckled on our Maryland license pads, meanwhile breathing a pious prayer that Chairman Terry's national license bill might soon be on the statute books. I should have said before that the motor vehicle law of Delaware permits non-residents to remain in the State for forty-eight hours without undergoing any license formalities. This is a liberal provision which certain other States would do well to copy.

The character of the country changed somewhat as we proceeded down through Maryland, and the road frequently led through woodlands, covered with fine second-growth pine trees. Some lumbering was going on, and we occasionally passed saw-mills. We noted the peculiar style of vehicles for carrying logs—a two-wheeled affair drawn by a pair of oxen and a horse. We could not fathom the reason for this strange combination, al-

though one of our party suggested that the oxen were for power and the horse for speed; in other words, a low-gear and high-gear combination. On reaching the town of Princess Anne at noon-time we were directed to the Hotel Washington, and here we had one of the surprises of our tour. The hotel impressed us favorably from the exterior. It was built in pure Colonial style, yet looked very modern, in striking contrast to the

hotels we had seen en route. We were ushered into a dining-room, every feature of which was prepossessing. Let me enumerate some of the articles on the bill of fare which I remember. Oysters—right out of the bay; fish—ditto; chicken—the kind you read about; asparagus—melt in your mouth, etc., etc. Served by Japanese waiters! And the price 50 cents!! We had to rub our eyes and pinch ourselves to make sure we were not dreaming.

Tearing ourselves reluctantly from this oasis we continued on our way, and after covering fifteen miles of zig-zag roads, such as I have already described, we came to a town having the euphonious title of Pocomoke City. South of this place we crossed into Virginia, and once more had to hang out another license number!

Accomac was the next town of any size, and then we began to think where we should spend the night. We brushed by the hotel at Tasley, and shuddered when we saw the accommodations that Onley had to offer. Finally we deter-

mined to spend the night at Onancock. This place was eighty-four miles from Seaford, where we had spent the previous night, and the reduced mileage for the day probably fairly reflects the less favorable character of the going.

We were glad to leave the hotel at Onancock early in the morning and proceeded southward through the unimportant towns of Keller (where the Standard Oil Company has a supply

IN OLD VIRGINIA'S WOODED COUNTRY.

station), Belle Haven and Eastville to Cape Charles, which we reached about noon. We had several hours to wait for the boat, which sails at 4:25 P. M., on the arrival of the train from New York and Philadelphia. For carrying our car to Norfolk we were charged the exorbitant rate of \$17.60. I have already taken this matter up with the proper officials, with a fair prospect that a more reasonable rate may be shortly extended.

We found Cape Charles to be 240 miles by road from Philadelphia, and, in the light of our experiences and observations, I would suggest the following schedule: In order to take advantage of the best hotel

accommodations, the first day's trip from Philadelphia should be terminated at Dover, twenty-six miles out. The Hotel Richardson in this city has a good reputation and looks good from the outside, although we did not have any personal experience with the place. The second day's trip is another comparatively short jaunt of seventy-seven miles to the Hotel Washington, Princess Anne, which has already been described. The third day a comparatively early start should be made so as to have ample

AN IMPROMPTU INTERVIEW WITH A FRIEND IN NEED.

time, in case of delays, to reach Cape Charles in time to go aboard the boat. If anyone is in so much of a hurry that he would like to make the trip from Philadelphia in two days, the best stopping place is Salisbury, 136 miles.

CAPE CHARLES, WHERE WE TOOK THE NORFOLK BOAT.

A GYPSY CAMP NEAR NORFOLK, WHERE YOUNGSTERS ABOUND. !

My personal opinion is that those who wish to see the exposition with the greatest comfort should disembark at the intermediate stop at Old Point Comfort (which is but 24 miles from Cape Charles) instead of going through to Norfolk (which is

VIRGINIA'S BUILDING AT THE JAMESTOWN EXPOSITION.

36 miles, by boat, from the Cape). The exposition is situated just across Hampton Roads from the point and is nearer to it than it is to Norfolk. One of the most impressive sights in connection with the exposition, in fact, the feature, which will be the most interesting to those who have visited other great expositions, will be the assemblage of warships of all nations which will anchor in Hampton Roads. The "front door" of the exposition, like that of everything else in the vicinity, is on the water front, and most of the visitors will come there by water. There is frequent boat service from the point to all places of interest in the vicinity. The point is a government reservation, and, while there is much military activity at Fortress Monroe, there will be less bustle and confusion in this isolated spot than in Norfolk. The great Hotel Chamberlain on the point is one of the finest resort hotels in the country, but it should be said, however, that the rates charged are fully in proportion to its desirability (plus the price-boosting influence of the exposition).

The vicinity of Norfolk is a better locality for boating than

CINCINNATUS AT HIS SPRINGTIME TASK.

ST. PAUL'S CHURCH, NORFOLK, BUILT BY THE PIONEERS.

for autoing. There are bays, rivers and creeks whichever way you turn, as the soil offers no resistance to the intrusion of water. Consequently, almost all traffic is by boat and the roads receive little attention. The road between Norfolk and the exposition is a disgrace to the community, particularly in view of the fact that there is considerable hauling of material over it to the exposition grounds. We had to use our shovel to get out of one soft spot into which we sank and we also pulled out several wagons that were stuck.

In conclusion, let me say that I believe in the wise old saying "When in Rome, use Roman candles." When around Norfolk do your traveling by boat and save your motoring energies for the trip back home. In a later article I hope to discuss one or more interesting routes of returning north.

NO CLIMB THIS YEAR ON DEAD HORSE HILL.

WORCESTER MASS., April 15.—The Board of Governors of the Worcester Automobile Club announces that there will be no climb this year on Dead Horse hill. It is understood that a premature announcement that the club intended to conduct such an event was called to the attention of Massachusetts Legislature members and resulted in the ultimate killing of a measure under which, if it became a law, the club hoped to secure permission from the State Highway Commissioners. The club was not responsible for the announcement, but under the circumstances it has abandoned the idea of the climb rather than appear as intending to go ahead even if it did not succeed in passing its law.

The recent Stockholm-Gothenburg race was a victim of the weather, as sleet, snow and strong winds combined to create as unpleasant circumstances as possible. Of the thirteen cars starting, only three finished, and of these a Fiat made best time in 39 hours.

ENTRANCE TO FORTRESS MONROE, OLD POINT COMFORT, VA.

MASSACHUSETTS ASSOCIATION HEALTHY.

BOSTON, April 15.—The annual meeting of the Massachusetts State Automobile Association was held at the clubhouse of the Bay State Automobile Association. President E. C. Lee presided, and the reports of the secretary and treasurer showed the association to be making good progress.

Chairman L. R. Speare of the Legislative Committee reported that his committee had been very successful in preventing objectionable legislation, particularly in killing measures intended to lower the speed limit. In regard to the taxation of automobiles, he said that he believed that the committee would report to the Legislature a bill for an annual fee of \$3 for registration.

The Signboard Committee reported that it has secured 1,000 signs, which it proposes to erect along the highways during the coming season. The secretary was instructed to notify the clubs that are members of the association of speed traps, and the Legislative Committee was instructed to have the old and obsolete signs removed, particularly those relating to speed rules.

The election of officers resulted as follows: President, E. C. Lee, Massachusetts Automobile Club; vice-president, John P. Coughlin, Worcester Automobile Club; secretary, James Fortesque, Bay State Automobile Association; treasurer, John C. Kerrison, Bay State Automobile Association; Chairman Legislative Committee, L. R. Speare, Bay State Automobile Association; Chairman Good Roads Committee, John P. Coughlin, Worcester Automobile Club; Membership Committee, W. H. Chase, Leominster; Henry W. Knights, Boston, and A. Burbeck, Brockton.

BOOKS FOR AUTOMOBILISTS.

A Work on Basic Principles.—"Motor Car Principles" is, as its title would lead one to suppose, a setting forth of the principles which underlie the construction of modern automobiles. Roger B. Whitman, the author of the book, and technical director of the New York School of Automobile Engineers, states in his introduction that the object of the book is to explain the principles that underlie automobile construction and operation and to illustrate the movements and mechanical combinations adopted in present-day practice. This is done in some two hundred odd pages with an absence of technicalities, and although the beginner will not by a study of the book learn all there is to be learned about the automobile, he will certainly gain a good deal of useful information. The book is published by D. Appleton & Co.

A Handbook of Practical Value.—The latest addition to the popular type of automobile handbook, "The How and Why of the Automobile," by Fay L. Faurote, fulfills what its author has set himself to achieve, namely to present a plain, easily-understood description of the modern automobile. Assuming that his reader knows nothing about the subject, the author introduces the automobile in as simple and untechnical a manner as possible. The entire field is covered, and covered so completely that the work can be recommended as a handbook for beginners or those with only a limited knowledge of this subject. The book is published by the Motor Talk Publishing Company, Detroit, Mich.

For Automobilists Touring Abroad.—For the convenience of automobilists touring in foreign countries the Bureau of Tours of the Automobile Club of America has compiled and published in book form a large amount of information on ocean freights, customs, rules and regulation in some forty foreign countries. As an example of the nature of the work it is only necessary to quote the arrangement for one country. For France, for instance, ocean freight is given to the different ports, landing charges, and customs are given in detail, registration of machines, driving certificate, road regulations, speed laws, and a list of the French automobile associations likely to be of benefit to the visitor are all dealt with concisely and accurately.

AUTOMOBILE CHANGE GEARS AND THEIR JOURNALS*

By HENRY HESS, MEMBER SOCIETY AUTOMOBILE ENGINEERS.

CHANGE gears are now so generally being mounted on ball bearings that such practice, not only with us, but in Europe as well, may fairly be considered as standard.

Within the past ten years I have had considerable occasion to suggest suitable bearings, very often without being given the necessary data. Questions would take some such shape as: "What bearings shall I use for the change gear of a touring

FIG. 1.—Well-mounted example of American gear.

car?" Requests for the power of the car, its weight, the intended arrangement of the gear were, not as infrequently as a gathering of engineers might think, obviously considered as a prying into affairs that did not concern the bearing makers.

At first sight it would seem a simple matter to take a given arrangement of gears, consider the power transmitted through them, their speed and position relatively to the journals and then, having calculated the load on the journals, pick out suitable bearings.

But—who knows how large a portion of the available maximum power of the engine is employed with any one gear reduction? Who knows for how large a portion of the average load hours the load is carried by a given set? Who knows what the average power exerted is, anyhow? Who knows what the maximum is for a 28-30-horsepower engine that is, however, said to really develop 40 on cylinder diameters for which other builders claim anything between 10 and 50?

Many Important Essentials to Be Considered.

Obviously, the only practicable way out is to reduce to some sort of system the results reached by experience and observation during many years—many, that is, as measured by the history of a lusty infant industry that has cheerfully honk-honked its way to the front rank, not even restrained by false modesty from putting "Gabriel's" horn to an earlier than the intended use.

As a failure to observe a few cardinal principles in mounting ball bearings may readily give unsatisfactory results, even when a suitable size selection has been made, a brief consideration of these principles is first in order. The illustrations given, are, as a rule, typical only, with a few exceptions, which are reproduced from the actual practice of builders who have courteously granted such permission, while others are reproduced from the pages of technical journals.

*Paper read before Society Automobile Engineers at New York.

1. See Fig. 1. One ball bearing only should be employed to a journal. The very natural resort to two or more light bearings to carry a heavier load will not answer. Slight inaccuracies of mounting, deflections of the shaft or housing, temperature effects, etc., will prevent the equalization of load between such multiple bearings, so that at times only one will be called on to do all the work. If it is not equal to that task it will go to pot, and the others will follow. Heavier bearings must be used for heavier loads, not more light bearings.

2. A bearing intended to take radial load should be so mounted that no end thrust may be imposed on it. For that reason either the outer or the inner race should be a slip fit. Were both races drive fits, the one on the shaft and the other in the housing, their seating would have to be by end pressure exerted through the balls, which would probably not be relieved, and so remain to reduce the bearing's radial load capacity, possibly very considerably.

3. The inner race should be a tight, and the outer a slip fit. This holds for all such sizes as are used in automobile work. The reason is that the continuous hammering of the load willpeen down the softer material of the shaft or housing and show this effect more on the shaft. Consider that as between opposing convex and concave surfaces of hammer and anvil the convex surface will be soonest affected. It is the shaft that is convex, and that is softer than the bearing, while the housing seat has the more resisting concave shape and the larger surface.

4. The inner race should be securely clamped between substantial shoulders on the shaft and a nut or its equivalent. This is because experience has shown that, although a drive fit is sufficient to hold the race, an intention to have a drive fit is effective only if translated into practice and only for so long as it is maintained after that. Pulling a bearing off and on a few times, or the reducing effect of the road peening will destroy the fit. But the frictional grip between a sufficient shoulder and a good nut will damp out the road vibrations so that the shaft will not be peened down.

5. When a shaft is to be secured against endwise shifting, whether in one or both directions, that office should be assigned to one bearing only, whose outer race should then be clamped between shoulders in the case. Observance of this rule will benefit the shop, since it is not only difficult, but costly to secure an accurate endwise relationship between shoulders on a shaft and a case. If such relationship is not secured then forcible

FIG. 2.—Typical illustration of good French practice.

FIG. 3.—A German type designed for 30 H.P. car.

assemblage will introduce un contemplated and destructive end thrusts. The same thing results from a deflection of shaft or housing, as well as from unequal expansion or contraction under the influence of temperature variation.

6. The bearings must be so housed in as to retain lubricant and exclude dust, grit, etc. An impression that ball bearings will operate without lubricant is more general than one might think. It is barely possible that absolutely true spheres might roll on absolutely true surfaces if both were made of materials that were absolutely inelastic and therefore would remain true under load. But since such absolute perfection of shape is not to be had, such possibility is not of interest to the practising engineer, who must, therefore, provide and retain lubricant.

Good Housings an Absolute Necessity.

Since not the wildest stretch of imagination will construe that grit is a lubricant, the necessity of its exclusion is, I should like to say it, apparent enough, were it not for the fact that I have run across mountings so exposing the bearings that grit from trap (or cement) rock-surfaced roads had, together with moisture, formed a cement ring between the inner and outer races, absolutely concealing the balls and binding the two races and the balls into a solid lump.

Fortunately, merely suitable shaping of parts will not only serve to retain lubricant, but also, at the same time, exclude foreign matter.

7. Rust and acid must be kept out. Experience and most carefully conducted tests have proven that long life under load can be realized from ball bearings only when the surfaces are not only true, but are also highly polished and smooth. Roughnesses will be broken down and leave still greater roughnesses. Rust and acid will destroy originally true and smooth surfaces. Since not a few lubricants contain free acids, care in their choice must be exercised. Plentiful lubrication and a properly closed mounting are safeguards against rust.

Fig. 1 is a familiar American gear, and is very well mounted: The inner races are clamped between shoulders and nuts or between shoulders, tubular distance pieces, the hubs (shown partially), or other elements outside the case, that are in turn driven home by nuts (not shown). The outer races are slip fits; those at one end are free endwise, while those at the other end are held between a shoulder in special containers and end cover caps.

The employment of bearing containers is optional. If the case is of rather soft material a container of harder material is advisable. Aluminum alloys are to be had nowadays sufficiently hard to take the bearings directly. Containers are preferred by some designers who wish to use a different lubricant in the bearing from that slushing the gears. Again, some use the containers as a convenient means for adjusting parts in their endwise relationship by simply shifting the containers in the case and with them the shafts, etc.

Fig. 2 is a fairly typical example of good French practice, of a correctly mounted 25-horsepower direct-drive three-speed gear. The end of the driven shaft is ball-journalled in the drive shaft, which is the reason for the rather large bearing carrying the inner end of the drive shaft. Bronze bushes at this point are also frequently used, but their greater wear influences unfavorably the action of the nearer gear pair.

Fig. 3, a German 30-horsepower gear, is, as to mounting, fairly like the preceding one, and employs no containers. A rather smaller bearing for the inner end of the drive shaft is made possible by mounting this farther back, instead of directly over the small bearing inside the clutches. This does not admit quite as good bearing conditions, as the drive gear is overhung, whereas in Fig. 2 this gear is supported between bearings.

Endthrust from bevel gears and bevel pinions may be, and is frequently taken on the same bearings that take the radial loads. Fig. 4 is a case in point. As a matter of course, such bearings are relatively heavier, since one pound of endthrust is the equivalent of from three to four pounds of radial load in its effect on the bearing. The bearing directly behind the differential box, that takes the bevel gear thrust, is therefore considerably larger than that supporting the other end that carries radial load only.

Space considerations sometimes make it undesirable to use a bearing sufficiently large to take both thrust and radial load. In Fig. 5 the bearings directly behind the bevels are, as regards their outer races, free endwise, and therefore receive no thrust. Similar bearings directly behind them are, however, as to their outer races, bound endwise, so taking thrust, but free circum-

FIG. 4.—Example using same bearing for thrust and radial load.

FIG. 5.—Use of separate bearings for thrust and radial loads.

FIG. 6.—French example of separated thrust and radial loading.

ferentially, so that no radial load can be imposed on them. A good example of similarly separated radial and thrust loading from French practice is shown in Fig. 6, while Fig. 7 is taken from English practice. A tendency characteristic of much British engineering is evident in the relatively large parts used. The bearing supporting the inner end of the bevel gear spool is of quite unusual dimensions. That is a fault to which the bearing manufacturer may draw attention as involving unnecessary expense, but which he is hardly likely to seriously oppose.

Many engineers prefer to take the thrust of bevel gears on ball bearings of the collar type—a practice which is certainly good. Fig. 8 is an example. The thrust bearing is mounted directly behind the bevel pinion. Alternative mountings are shown above and below the center line. Above, the spherically faced adjusting surface for the stationary plate is machined directly into the case; below, a concaved washer is employed, as giving rather simpler shop work. Alternative mountings for the differential shaft are also indicated on opposite sides of the center line. In one a smaller thrust bearing can be employed, carrying that on the shaft, as against a larger bearing demanded by the mounting on the bevel gear hub; this last mounting, however, is rather simpler, mechanically.

The various modifications of mountings likely to occur in practice have been fairly covered by those shown, so that I shall now take up the size selection.

Load Data Collated from Numerous Examples.

Since, as has been previously stated, size selection is based on experience rather than on mathematical deductions from insufficient premises, this chapter will be confined to giving in simple diagrammatic form recommendations of suitable bearings for various typical gear arrangements. Obviously, it would

not be proper, since much matter is submitted confidentially for our advice, to give actual practice. The examples are, therefore, taken from résumés of gear arrangements in the *Horseless Age* and other periodicals, and hence of general knowledge. The names given with each example are those given in the publications. In arriving at the loads imposed on the bearings, no attempt has been made to take into consideration change of engine speed with different gear sets in engagement, but bearing size suggestions are all based on an assumed engine speed of 1,000 r. p. m. to develop the horsepower cited. Journal load figures and bearing sizes may, therefore, be modified by direct proportion for other powers or speeds.

(To be continued.)

HOW SIZE MAKES FOR COOL RUNNING.

Given a certain load upon a journal, a certain amount of heat must be generated under certain other conditions, says *The American Machinist*. The heat generated may render the lubricant more fluid. If a bearing be short, the heat generated will be stored in a smaller mass of metal than if the bearing be long, and the temperature will be higher with the shorter bearing, and the more liquid oil will have less supporting power and the bearing may run metal-to-metal, with the further result of more heat generation. Hence a reason for advocating long bearings. It should not be forgotten, in discussing questions of the proportion of bearings, that a long bearing, having larger radiating surface, will part with more heat than a short bearing, so that increase of length acts in two ways: It keeps bearing cooler because it radiates more heat and it better prevents metallic contact because the oil better retains its supporting powers, and the supporting film is more difficult to force out. But neither must it be forgotten that long bearings have their limitations. The oil in a bearing has viscosity or adhesiveness, and length increases the opportunity for the retarding effect of stickiness.

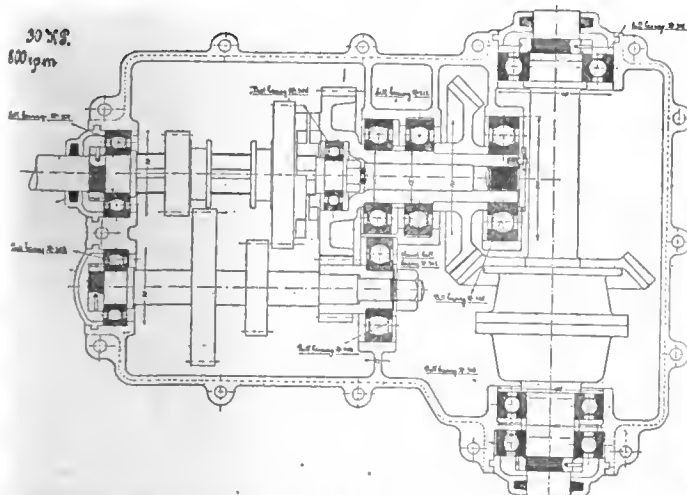

FIG. 7.—English example separate thrust and radial loading.

FIG. 8.—Thrust of bevels taken on bearings of collar type.

AUTOS FOR THE HORSELESS AREAS OF THE WORLD

"QUEER Transportation Methods" was the title of a lecture delivered before the National Geographic Society at Washington, D. C., Friday evening, April 12, by O. P. Austin, Chief of the Bureau of Statistics of the Department of Commerce and Labor. The lecturer took his audience through tropical America, Northern Africa, the Holy Land, India, Burma, the Malayan peninsula, the Philippines, China, Korea and Japan, showing by a large number of illustrations the crude methods utilized—the burro of Mexico; the llama of South America; the sledges of tropical Madeira; the saddle ox of central Africa; the camel of the desert; the donkey of North Africa and Arabia; the bullock cart and the dandy of India; the yak of Tibet; the trotting ox of Ceylon; the elephant of Siam; the carabou of the Philippines; the wheelbarrow and sedan chair of Japan; the pack bull and palanquin of Korea, the jinricksha and kago of Japan, and the coolie freight carrier of the Orient.

This problem of the development of the tropics and the Orient, which had been so long delayed by reason, in part at least, of the absence of the horse for transportation between the point of production and the common carrier might now, in Mr. Austin's opinion, be solved by the substitution of the horseless freight carrier of the automobile type for the crude methods which have prevailed in those sections of the world in which the horse is not available and never can be used profitably.

Progress Impossible Without Transport Facilities.

"Of the 100 million horses, more or less, known to exist in the world," he said, "80 million, or four-fifths of the entire number, are found in the temperate zone and nearly all among occidental people, while the remaining 20 millions are largely employed in the service of temperate zone visitors or residents, and are but feeble representatives of that noble animal as he is known to the people of Europe or America." In the United States and Canada we have 1 horse for every 3 1-2 persons approximately; in South America, 1 for every 7; in Mexico, 1 for every 12; in Japan, 1 for every 33; in Turkey, 1 to every 40; in the Philippine Islands, 1 for every 50 (in Africa, 1 for every 150; in India, 1 for every 200), while in southern China, for which no statistics are available, the number is probably even less.

No man who has visited the tropics and the Orient can fail to realize the great disadvantage under which tropical and oriental man has labored in his attempts to develop exploration, intercommunication and exchange of products; and the great benefits to science and commerce which would come from a satisfactory device which would do for the tropics and the Orient what the horse has done for the temperate zone of the occident. Clearly the conditions of transportation in the tropics and the Orient are due, in part at least, to the absence of the horse. Now comes the final question, of whether the ingenuity of man may provide a substitute for the horse, which can be utilized in those areas where the horse cannot exist. This may now be answered in the affirmative. For many years man has been experimenting in attempts to transport merchandise and men by some machine which carries within itself its own propelling power. He soon learned that he could drive a wheeled vehicle on land by power produced within itself, provided he supplied it with an iron or steel track on which its wheels might run; and with this knowledge the railroads spread over all that part of the world where horses could be found to bring the products to their stations.

Coming of the Passenger and Freight Automobile.

But until the beginning of the twentieth century man had not solved the problem of operating self-propelled vehicles on ordinary dirt roads or across stretches of country in which no roads exist. That art has at last been attained. The introduction of the bicycle brought the rubber tire and the application of the rubber tire brought a self-propelled vehicle which could be oper-

ated on country roads, the automobile. Then came the development of the freight motor, the self-propelling vehicle which would carry heavy loads of merchandise over the ordinary highways; and to-day thousands of horseless vehicles are moving hundreds of thousands of tons of merchandise over roads of a type which can be supplied everywhere.

Automobile Freighters Invading Every Land.

The practicability of applying the self-propelling vehicle to transportation in deserts, in the tropics and the Orient has already suggested itself, and the experiments made have already assured success. In the deserts of New Mexico and Arizona motors are successfully working at temperatures of from 120 to 140, where horses or mules can only be used at night. In Nevada motor trucks are now performing the work of thirty horses each, carrying freights over 100 miles of mountain roads. In California motor cars are carrying over dirt roads in the mountain regions as much ore at each trip as would require 100 pack horses. In Puerto Rico a line of three motor vehicles carries passengers and mails, performing the work of more than a score of vehicles and over 100 horses. Numbers of American motor vehicles have been put on the roads of Cuba and Santo Domingo with success, and more are being ordered. In Honduras American motor trucks are conveying minerals to the seaboard from the mines 100 miles inland, a single automobile truck doing the work of 100 mules. In South America the horseless vehicle is carrying passengers and freights to inland cities at an enormous saving of time and expense. In Egypt the freight and passenger motor is beginning to take the place of the camel, and roads for their use are being constructed through the desert on which the product of the emerald mines will be brought to market. In Turkey motor cars are making regular trips over country roads carrying both freight and passengers. U. S. Consul Michael reports that the Indian Government is considering the desirability of utilizing motor transport wagons for moving the products of the outlying districts. Special Agent Crist reports a rapidly increasing use of the automobile in South Africa, especially in the mining regions; that nearly a million dollars' worth of these vehicles were imported in 1906, and that the cost of constructing motor roads is only about one-eighth as much as that of railways. In the Congo the Belgian Government is constructing hundreds of miles of roads for the use of the motor in the transportation of freights in that section. In Java an American automobile is being used for the transportation of mails over the country roads of that island. In Japan experiments with the motor car have been so successful that a company has recently been organized in that country with a capital of 10 million yen for the purpose of building and operating vehicles for a general transportation service in Tokyo and thence to the surrounding towns. In the Philippines a line of motors is being put on to carry passengers pending the completion of the railway. A special type of vehicle made in Paris has now trains of horseless freight and passenger trucks operating over country roads in the continent as well as in Algeria, Central Africa, Chile and Peru. Finally, so confident are those acquainted with the horseless vehicle and its ability to operate in the tropics and the Orient that a race of motor vehicles from Peking, China, to Paris, France, a distance of 9,000 miles across the great Gobi desert, is planned for next June.

HOW TO FILL CAST-IRON BLOW HOLES.

Holes in cast iron may be filled by the following alloy: Melt together nine parts of lead, two parts of antimony, and one part of bismuth, and pour this mixture into the hole, first somewhat warming the hole, says the *Mechanical World*. This alloy possesses the quality of expanding when cooling, hence becomes solid in the holes when cold.

LETTERS INTERESTING AND INSTRUCTIVE

The Question of Steel versus Castiron Pistons.

Editor THE AUTOMOBILE:

[704.]—In an experimental automobile I am about to build, I wish to use steel cylinders, probably in connection with steel pistons, for the sake of securing a maximum of strength and lightness, but I do not feel altogether safe in disregarding the general condemnation of steel cylinders which seems to exist in the comment of all who have tried them. Nevertheless, it is my opinion that there are enough mechanisms in which steel-to-steel bearing surfaces are used with good results to indicate fault in the application rather than in the principle of using steel for this purpose. What, in detail, if you will please tell me, are the troubles actually found with steel cylinders? Do they seize, wear too rapidly, warp—or what? I fully understand that ordinary cylinder iron is believed to contain enough free graphitic carbon to act as a lubricant, but the value of this cannot be very great because cast-iron-to-castiron quickly seizes when run dry, showing that chief dependence must be placed on the lubricating oil, after all. And why is not a castiron piston all right in a steel cylinder?

Lakewood, N. J.

E. H. HOUSMAN.

The question you raise undoubtedly is in a considerable degree an open question, still subject to settlement as automobile building advances, though to-day the general practice of the industry is overwhelmingly in favor of castiron and against steel cylinders. Steel cylinders tend to seize, principally, no matter how well their lubrication is looked after, but it is a fact, bearing out what you say, that there are occasional instances found of their successful use. It probably is not so much the free graphite in castiron that gives it its value as it is the presence of minute pores which trap globules of oil (becoming oil-soaked, as it were) and thus facilitate lubrication. Castiron to steel does work better than steel to steel. Once seizing commences, it produces rapid wear and overheating, but these seem thus definitely to be effect rather than cause. In attempting to use steel, too close a fit should not be attempted, or differences in size due to variations in temperature may aggravate the troubles that are difficult to avoid at best. In the Christie car, which is the American entrant in the coming Grand Prix, and which was described in last week's issue of THE AUTOMOBILE, pistons and cylinders are of steel, but the two are absolutely prevented from coming in contact by the ingenious expedient of casting two broad bronze bearing rings directly into grooves turned in the surfaces of each piston. This engine has seen some hard service and has given no trouble whatever. A suggestive fact, because of its bearing on this problem, is the little-appreciated quality of hardened steel to hardened steel for shaft bearings, this combination being widely used by conservative engineers of standing for the heaviest and most exacting services—provided the conditions are such that complete and unflinching lubrication is absolutely assured. Otherwise its use is not even to be considered.

Two-Cycle Engine Dimensions.

Editor THE AUTOMOBILE:

[705.]—Will you please publish the full dimensions of a good two-cycle gasoline engine? SUBSCRIBER.

Chicago, Ill.

There is so little unanimity among even the best qualified designers as to what proportions are most satisfactory for two-cycle engines, that it is difficult to give you figures which will be in no way beyond criticism. Probably the following come about as near as is possible to an average of the best current practice: Bore, 4 1-4 inches; stroke, 4 inches; exhaust port, 3-8 inch deep and 3 inches wide; bypass port, 1-2 inch deep and 3 inches wide; intake port (assuming that you have in mind a three-port engine), 1-2 inch deep and 3 inches wide; deflector straight, and one inch high; connecting rod, 8 inches long; piston pin, 1 inch in diameter; crankpin and crankshaft, 1 1-2 inches in diameter; cylinder walls, 1-4 inch thick; water jacket space, 5-8 inch, and piston length, 6 inches. In a two-port engine a 2 1-2-inch flat poppet valve with a 1-8-inch lift will serve in place of the intake port.

How to Connect Up an Apple Ignition Set.

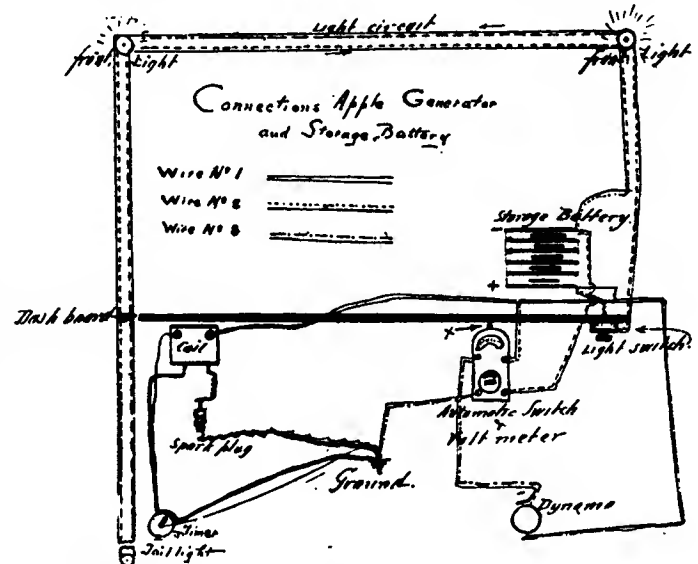

Editor THE AUTOMOBILE:

[706.]—Will you please let me know through "Letters Interesting and Instructive" if the connections of my dynamo and storage battery are correct, as per sketch enclosed? You will notice that the connections are the same as illustrated in No. 10, March 7th, of "The Automobile." Now, having established the wiring as shown, I turned the switch on and started the machine. Do not know exactly on what section the switch was, I presume it was in amp. charging, when, after a while, I saw smoke going out from the voltmeter, and before I could stop the current the voltmeter was completely burnt and out of service. I looked all over the system to see if there was a short circuit somewhere, but could not find it, and saw everything properly adjusted as per sketch.

The only apparent cause (to my understanding) of the overheating and burning of the system seems to be the different kinds and diameters of the wires: wire No. 1 being double insulated thick for secondary work; No. 2 common lamp cord half the size of No. 1, and No. 3 also cord of half the size of No. 2. Have also noticed that my "Apple dynamo" heats; after running an hour or two it scarcely can be touched with the hand.

The storage battery is a 6-volt 60 ampere-hour system. I beg to ask you the following questions:

1.—What was the cause of the burning of the voltmeter, and how can I prevent it?

SKETCH OF IGNITION AND LIGHTING CONNECTIONS.

2.—In the spot marked by an arrow is a hollow nut where an electric cord or wire may be inserted, such wire or cord was lost en route, and the instrument came to my hands without it. Is it necessary and how used?

3.—Will the different diameters of wire have a bad influence upon the current and determine the overheating of the conductors? If so, what kind or size of wire or cord must be used?

As I am a subscriber to "The Automobile," will you kindly answer these questions, and believe me yours truly,
San Luis Potosi, Mexico.

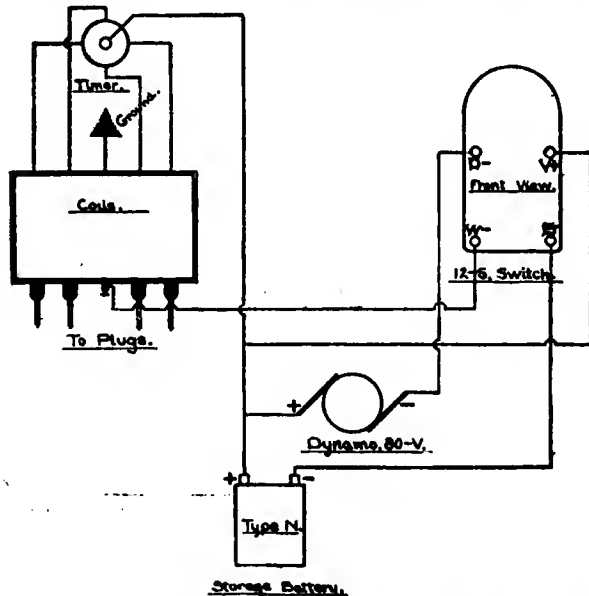

STRANGER, L. B.

1.—The cause of the voltmeter burning out, as you describe in your letter, was evidently due to an internal ground, or short circuit, against which you could naturally not guard, unless, as many autoists and people generally, for that matter, have a habit of doing, you took the instrument apart "to see the wheels go round" and did not get it together again properly. The makers of the apparatus, to whom we have referred your letter, assure us that the wiring is correct if connected up in accordance with the diagram you submit. The different sizes of wire used would have no bearing on the matter, i.e., the overheating, provided connections were all well made and wire of reasonable current-carrying capacity were used.

2.—The makers inform us that the hole in the top of the meter is not for the insertion of a cord, as you surmise. It was origi-

nally placed there for the purpose of accommodating a small push-button, by means of which the voltmeter could be bridged across the line in order to obtain a reading. It has been displaced by the snap-switch on instruments of more recent make and is no longer in evidence on the latter.

3.—As already mentioned, the different sizes of the wire used would not influence the action of the apparatus one way or the other, unless wire of such small cross section were employed

WIRING DIAGRAM OF APPLE DYNAMO AND ACCUMULATORS

that the amount of current used would tend to overheat it. Nothing smaller than 18 B. & S. gauge copper wire should be used, and the makers recommend Packard primary cable for the low-tension wiring, this being a built-up or flexible cable, which is the equivalent of about 16 gauge.

Regarding the overheating of the generator itself, it is equally possible that this may be due to purely mechanical reasons, such as lack of oil on the bearings, as that it is suffering from some electrical defect. Or, again, you may be running it at an excessive speed, thus putting a considerable overload on it, which would soon cause overheating. The makers have sent us a sketch, showing the proper connections, which we are reproducing together with your own, and they advise us further to have you return the burnt-out switch panel directly to them.

Horsepower and Other Things in General.

Editor THE AUTOMOBILE:

[707].—Will you kindly give me a little information through "Letters Interesting and Instructive" regarding the horsepower of an automobile I am about to purchase. What I wish to know is what is the normal horsepower at say 900 revolutions per minute. Also, maximum horsepower, full speed of motor being about 1,600 revolutions per minute. Also, please state about what speed car could make on an ordinary good road. Following specifications will give data on which answers to the above can be based: Run-about body; weight (entire car), 1,300 pounds; wheelbase, 80 inches; tires, 28 inches by 3 inches; tread, 56 inches; double-opposed four-cycle motor, water-cooled, $4\frac{1}{4}$ -inch bore by $4\frac{1}{2}$ -inch stroke; valves, mechanically operated; jump-spark ignition; car is single-chain driven of heavy Brampton type and is geared about 4 to 1. Springs and axles are extra heavy type. I wish to have a light tonneau made for this car, making it a light touring car. Would you deem this advisable?
A. SUBSCRIBER.

Cleveland, O.

Asking us to tell you the horsepower of your motor with the data supplied by your letter, is, we fear, somewhat overrating the omniscience of the editor. There are other considerations and somewhat important ones, by the way, such as the compression, for instance, on which your letter is silent. But even if you had given us all the data necessary to figure the horsepower, we fear very much that it would not agree with the

maker's rating. Probably you can recall the state of affairs that prevailed a few years ago in this country, when the ratings of a number of motors that differed so little in detail as to be hardly distinguishable apart, were so much at variance that one scarcely knew what to believe, and the sarcasms "catalogue" horsepower, "dream" power, "motor" power, and a few others of the kind sprang into current use. This was particularly the case with the double-opposed horizontal type of motor, some of which were rated all the way from 12 to over 20 horsepower on practically the same dimensions. Assuming the compression of your motor to be about 60 pounds per square inch, we should say that it ought to develop about 10 horsepower at 900 r.p.m., and probably 12 to 15 at 1,600 r.p.m., but if it is designed to deliver its rated output at the former speed, should not recommend running it at the latter figure. As the weight of the car is well proportioned to its power, it should probably be able to run as high as 30 miles an hour under favorable conditions on the level, but with such small wheels, we have no doubt you will find 25 miles an hour about as fast as you can go with comfort on any but the smoothest of roads. We should recommend the use of at least 30- by $3\frac{1}{2}$ -inch wheels and tires, this being the size specified by all American tire makers for a weight of 450 pounds per wheel, which your car will probably exceed with four passengers up. It would not be advisable to put a tonneau on without increasing the size of the tires as indicated, the result being endless tire trouble otherwise.

Omitted in Answering Letter Number 703.

In publishing letter number 703, from F. P. Covert, Hovington, Kas., which appeared in the last issue of THE AUTOMOBILE, the fact that it called for an answer was inadvertently overlooked. It contained the following question: "How much loss of power would there be in compressing air in a receiver and using it in a simple engine such as is used with steam?"

This would depend to a very large extent on the purpose for which the power was to be used, how far the engine was to be located from the air-compressor, and a number of other factors, but generally speaking, the efficiency is rather low. There are several sources of loss: first, the air-compressor itself, the efficiency of which would probably be 80 to 85 per cent.; second, loss occasioned by pumping the warm air of an engine-room in the case of a stationary plant, which, of course, would not be present if you refer to its use on an automobile; fourth, friction in the conducting pipes, this being excessive if the pipe is very long, as in the case cited by an engineer of a water-power air-compressor plant transmitting its power three miles to mining machinery through a 24-inch main; but 390 horsepower was delivered of 1,430 generated at the falls. In an extensive system of compressed-air distribution service used in Paris some years ago, it was found impossible to make a commercial success of it, unless the air were heated prior to use. It is also very difficult to entirely prevent losses from leaks. Experiments extending over a number of years have been made in this country with street cars using just such a system as you mention, *i.e.*, air compressed in receivers and expanded in double-acting engines similar to those used with steam. That they were finally discarded as commercially impracticable after long experiment and investigation would appear to conclusively demonstrate that the losses are excessive.

Editor THE AUTOMOBILE:

[708].—I remember seeing some formulæ for aluminum solders printed in "The Automobile" two or three months ago—I think it was one of the January issues, and would like to know if I can obtain a copy of that number. I am already a subscriber, but would like to get another copy of that issue.
R. W. SHEARER.
Chicago, Ill.

We recall the fact that the formulæ you refer to were printed in THE AUTOMOBILE around the time you mention, but are under the impression that the issue was one of the special show numbers, which are out of print. We are accordingly repeating the same formulæ herewith for your benefit. One part aluminum;

one part 10 per cent. phosphor tin; 8 parts zinc and 32 parts tin, all by weight. This is said to make an easy flowing solder with which Canada balsam is used as a flux. Another formula is composed as follows: 80 parts tin, 20 parts zinc, using a flux made of 80 parts stearic acid, 10 parts chloride of zinc, and 10 parts chloride of tin. Pure tin fusing at 250° Centigrade has also been used as solder for aluminum. The use of chloride of silver as a flux has been patented and is said to give good results with ordinary soft solder. The difficulty in soldering is said to result from its extremely high heat conductivity, which withdraws the heat of the molten solder so rapidly that it "freezes" before it has time to flow sufficiently. A pure nickel soldering bit is used where it is desired not to discolor the aluminum, this resulting from the use of a copper bit. The fact that aluminum oxidizes instantly the moment a fresh surface is exposed also renders soldering difficult.

Wiring Connections for an Automatic Cut-out.

Editor THE AUTOMOBILE:

[709.]—How should an automobile cutout be wired? What size wire and how many turns in the coil, say for a dynamo of 15 v. 3 amp. output?

Will a series wound dynamo deliver current through a coil bridged across it, or should the automatic cutout be wired in series with the storage battery from the dynamo?

What prevents the storage battery remagnetizing the coils of the cutout when the dynamo stops? Should the tension spring in the cutout be strong enough to hold anything less than 6 v. for a 6 v. accumulator and release and close the circuits when the current reaches above that point? J. W. SMITH.

Chillicothe, Ill.

(1) The connections to the cut-out will depend more or less on the wiring of the remainder of the system; if the dynamo is only to be employed in charging the accumulators, the current from the latter being used for ignition at all times, then the cut-out should be wired in series with the generator so that upon coming into action it throws itself into shunt or across the line, and connects the storage cells in series with the generator.

(2) As by cut-out, we presume you mean simply an under-load circuit-breaker, the number of ampere turns required on it will be determined by the maximum amperes of the charge and the amount of magneto-motive force needed to actuate its armature, so that the amount of wire needed will depend largely upon the rest of the design.

(3) A shunt-wound dynamo should be used for charging and the cut-out wired in the circuit as already mentioned.

(4) When the current drops below a determined minimum the spring of the cut-out which always tends to break the contact against the magnetic force generated by the current, pulls the armature away and severs the connection, both between the dynamo and the accumulators and between the latter and itself. When the cut-out is not in action, there is no connection between it and the accumulators, but only to the dynamo, so that the generation of a current by the latter serves to operate it.

(5) As a three-cell battery reaches 7.5 volts or slightly in excess of this while on charge, the circuit-breaker should become operative at anything less in order to prevent the battery discharging through the source of the current in case its voltage should exceed that of the latter.

Information Wanted Regarding the Brush Runabout.

Editor THE AUTOMOBILE:

[710.]—Will you kindly inform me if, in your opinion, the Brush runabout is all the makers claim for it?

Also, is it good practise to place the whole plant of an automobile directly on the frames and axles? I believe the Brush car is so constructed, there being no springs to absorb the road shocks that naturally would be transmitted to the motor and machinery. Hartford, Conn.

W. C. WILLSON.

While we aim in this department to be of as great assistance as possible to our subscribers in all matters pertaining to automobiling, it should be apparent to you on a moment's considera-

tion that you are asking a manifest impossibility in the present instance. To reverse things, it would be as appropriate for you to ask the manufacturers of the Brush runabout if THE AUTOMOBILE were all its publishers claim it to be.

Regarding the latter part of your letter, we must also inform you that it is not the province of this department to criticize current designs, particularly as represented by new cars that have not yet undergone the test of time in a number of owners' hands. All we can say is, that the car in question is the work of a well-known designer, and was presumably not uncovered before having been put to a very thorough trying-out behind the scenes, as is the case with every engineering work. It is not customary in this or any other field of engineering endeavor to rush untried and untested machines on the market. Some makers of automobiles attempted to do so in earlier days, but soon were brought to a realization of the futility of such a plan. Your impression that there are no springs whatever to absorb the road shocks and prevent them being transmitted directly to the motor is quite erroneous, as you will note at a glance in the illustration of the car published in THE AUTOMOBILE some time since. If you wish to inform yourself regarding the car as a prospective purchase, we have no doubt that the makers will give you any reasonable form of demonstration to substantiate their claims for it.

Another Subscriber Who Thinks Well of This Department.

Editor THE AUTOMOBILE:

[711.]—In your issue of March 28, a subscriber writes that he finds "Letters Interesting and Instructive" worth the price of a year's subscription. I agree with him. Such information comes from owners of cars and not from dealers. In one of your issues of February you answered some questions of mine. Parts of my questions and your reply have been referred to several times by other correspondents.

I wish to say that your suggestions as to cause of my trouble I found to be correct; camshaft on inlet side was considerably out of where it should mesh with crankshaft. As there were plain punch marks on camshaft gear and on crankshaft, it was quite easy to adjust (that is, after one knew). Also, I found that another man to whom I had taken car had tried to fix it by advancing timer. He had advanced it so far that spark came just as exhaust valves opened. I am now overhauling this car myself, replacing some sprockets, cones, and balls, and I think the car will run as well as ever.

In your issue of March 28, a subscriber asks as to direct current from dynamo to coil. Perhaps my experience may interest him. During the Boston show of 1906 I saw and asked a lot of questions of the representative of the Dayton Electrical Company. I bought one of their outfits, battery charger, storage battery, autometer cutout; had full directions as to putting same in my car and carefully followed them. Starting engine from dry cells, charger seemed to run all right; when I switched from dry cells to Dayton outfit, engine stopped, I seemed to get current from charger to autometer and out on dashboard of car, but there it stopped. Ran car to a garage and they tried it with same results. They then tried wiring direct from charger to coil, started engine from dry cells and switched to charger, engine raced and a stream of sparks flew from vibrator on coil. Testing voltage showed 15 volts. While this lasted but a few seconds it cost me considerable to have coil repaired. I then returned outfit to makers and they sent me a full new outfit, all parts tagged as to wiring. I have never tried this second outfit and have it just as received. I think I could use it if I could regulate the charger and cutout (not using the storage battery) so that charger would not give over six volts at coil.

As I own two cars, one a four-cylinder air-cooled gasoline, and the other a White steamer, and as I take entire care of both, I have quite a variety of parts to look after.

Dunbarton, N. H.

C. F. M. STARK.

Even the editor likes a bit of taffy now and again, so that we are pleased to learn that our suggestions happened to hit the mark in your case and proved of actual assistance. It is rather more of a rarity to be complimented on having been right than to be taken to task for being wrong, though we note that some of our worst accusers fail to respond with a bill of particulars when we plead to the indictment and ask for further details of the error. However, the value of this department does not lie so much in the assistance that the editor can give the subscriber as it does in the fact that it constitutes a practical clearing house

for the interchange of actual experiences in taking care of cars and in overcoming difficulties, between thousands of subscribers in different parts of the country, and we have no doubt that there are many autoists who will agree with you and the writer you refer to, that this is a privilege well worth the price of a year's subscription. We are always pleased to be of assistance, if possible, when you are in trouble, or to convey your suggestions of a remedy for some other subscriber's trouble, through the columns of THE AUTOMOBILE.

Regarding the matter of the Apple dynamo and charging set, your letter is opportune, as you will note by the answer given to Stranger L. B., San Luis Potosi, Mexico, which you will find in this issue. The maker's wiring diagram, reproduced herewith, should be of assistance in installing the system in question, but if not we will be glad to help you out further.

Laying Out Steering-Pivot Arms.

Editor THE AUTOMOBILE:

[712.]—Being a subscriber to "The Automobile," I have taken much pleasure in reading your "Letters Interesting and Instructive." Since your inquirers receive such interesting information, I am taking the liberty of asking you for a little information. Will you kindly tell me what formula is used in calculating the angle made by lines through the center of the steering pivots and the steering-pivot-arm ends with the line connecting these two ends? I understand that this angle decreases with either an

METHOD LAYING OUT ANGLE OF STEERING KNUCKLES.

increase of wheelbase or tread, but I do not know in what proportion. In order to keep the forward wheels from binding on their bearings when turning a corner, this angle should be exact and I would be pleased if you would give me a formula taking into account the wheelbase and tread combined.

Otto, N. Y.

DAVID L. BROWN.

A rule widely followed is to have the steering-pivot arms in position for straight-ahead travel lie along lines drawn from the centers of the steering-pivots to the center of the rear axle. This, of course, applies only to rearwardly-extended pivot arms, used in connection with a drag link behind the front axle. With the drag link in front of the axle, the pivot arms may be practically in registry with the forward prolongations of the lines mentioned. There is no hard and fast rule invariably followed, however, in the laying out of steering gears—each designer usually having his individual preferences, which will be found applied in the constructions for which he is responsible. It is not possible—without most objectionably-complicated linkages—to produce a steering gear serving the same ends as the accepted type, which shall function correctly at all angles of turning. One or both wheels are bound to be at slight angles to their direction of travel in at least some positions. Consequently, there is afforded a choice between the policy of distributing the unavoidable error as nearly as may be through all angles, and that of minimizing it in the more nearly straight-ahead positions at the expense of the less-utilized wider angles of turning. Theoretically, lines drawn through the axes of all the vehicle wheels should meet at the center of the circle about which the car is driven. With this fact in mind, a few moments of work with paper and drawing instruments will quickly demonstrate an abstrusity which, it must be admitted, the problem does not appear to possess upon a casual consideration; hence, the method referred to above.

The Early Benz Engines.

Editor THE AUTOMOBILE:

[713.]—If you will be so good as to tell us, through the correspondence pages of "The Automobile," whether the old Benz cars, made in Germany, were propelled by two-cycle or by four-cycle engines, you will settle an argument that is causing myself and two friends some agitation. My friends, one of whom declares he drove an old belt-driven Benz, insists it had a four-cycle engine. I, on the other hand, have a distinct recollection of reading that these cars were driven by two-cycle motors—making the use of the two-cycle principle by Benz antedate the work of Clerk, who is commonly regarded as the inventor of the two-cycle engine. Hartford, Conn.

AN OLD TIMER.

The first patent issued to Benz and Company bears the date of March 26, 1884, and was for a two-cycle engine, which was used in the very first Benz cars. It failed to prove satisfactory, and at a very early date was discarded in favor of a four-cycle motor of such evidently superior construction that numbers of them still are in use in Europe. You are wrong, however, in assuming that the Benz two-cycle engine was an anticipation of the work of Clerk, who certainly produced a two-cycle motor at as early a date as 1882. In construction, the first Benz engine bore little resemblance to the two-cycle motors of the present day. It was fitted with a disk, instead of the now almost universal trunk piston, and a crosshead and a double-end cylinder were used, as in steam practice. The cylinder space beneath the piston was used for the precompression now commonly performed in the crank chamber, and pure air was handled here instead of mixture. A bypass pipe, closed by a mechanically-operated poppet valve at its upper end, connected the two ends of the cylinder, and in addition to this there were two other mechanically-operated valves—an exhaust and a fuel valve—opening into the combustion end of the cylinder. The operation was peculiar. At the end of the power stroke the exhaust valve was opened and as soon as this reduced the pressure enough the air compressed beneath the piston would flow through the bypass and hasten the exit of the remaining gases by a scavenging action. To insure this result the bypass valve was opened at about the middle of the exhaust stroke by a valve mechanism. Immediately after midstroke both exhaust and bypass valves were closed and compression commenced, during which gaseous fuel of liquid-fuel vapor was positively pumped in by an auxiliary pump, until the desired mixture was produced ready to fire. Probably the one particularly interesting feature amidst the crudity of the general design was the fact that this engine handled its charges expansively, expanding the burning gases to double the initial charge volume before exhausting. This helped both cooling and efficiency, and made for a silence of operation at that time less common than it is now.

What Is the Cause of Overheating Here?

Editor THE AUTOMOBILE:

[714.]—I would like to ask a few more questions, if it isn't too much trouble to answer them. I see by my letter (No. 658) that my account of my trouble is not very explicit.

The engine seems to go when the throttle is opened about a quarter of an inch, but does not ignite every time when starting, but does ignite when running, but leaving the throttle open in that way heats the engine too much and stops it.

Meshoppen, Pa.

H. N. F. CRAIGE.

Without any further information than you give in your letter, we should say that the symptoms point to carbureter trouble. Probably the mixture is too rich, which may account for the failure to ignite regularly when starting, provided, of course, that the ignition and other essentials are all in good order. Assuming that the engine is properly lubricated and does not stop owing to the lack of oil when it gets warm, the latter part of your letter would appear to confirm the diagnosis of too rich a mixture. We should think that running with the throttle further open would remedy the trouble, as it hardly seems possible that the engine would pull with any amount of load on when the throttle was open but a quarter of an inch, and so far as running under no load is concerned, it is by far the better plan to stop the engine altogether when not in use.

THE Pennsylvania automobile makes its bow to the public as a high-class machine sold at a moderate price, just sufficient to cover the cost of designing, materials, construction and selling, plus a fair profit, and nothing more. As a new comer it has yet to make a record, and it is only because that record is not made that it is offered at a lower price than the majority of machines of its class.

Two models are built by the Pennsylvania Auto Motor Company, of Bryn Mawr, Pa., and handled in New York by R. T. Peckham, 2234 Broadway. One is a touring car, the other a runabout shorter in wheelbase by about four inches, but similar in all mechanical features. Thus a description of the touring car will serve for the two models.

The frame is of pressed steel, eight gauge, 41-2 inch vertical spread, with 11-8 inch flange at top and bottom, narrowed at the front to give a wider steering angle. A pressed steel sub-frame is provided for the motor and transmission gear. Wheelbase is 112 inches, tread 56 inches. The frame is hung on semi-elliptic springs in the front and rear, with a transverse platform spring in the rear. Dimensions are 40 inches by 2 inches.

Motors.—The motor is a four-cylinder vertical Rutenber, 4 1-2 inches bore by 5 inches stroke, developing 35 horsepower. Cylinders are cast separately, with bearing between each; the inlet and exhaust valves are on one side, operated by a single camshaft. Ignition is jump spark by accumulators and four unit coil carried on the dash. The commutator is located on the upper end of a vertical shaft between the engine and dashboard, where it is accessible and out of the way of oil and dirt. The well-known Schebler carbureter is employed and

throttle and spark are controlled from levers on the steering wheel, but not rotating with the wheel. The engine is lubricated by means of the Kinwood mechanical pressure feed lubricator positively driven by an eccentric and belt from the vertical timer shaft. The engine is water-cooled and has a cellular radiator with water circulation assured by a gear-driven centrifugal pump. A belt-driven fan behind the radiator draws in a powerful draught of air. A new exhaust manifold, specially designed for the Pennsylvania car, permits of ready access to the valves.

Clutch and Transmission.—The cone clutch is of 10 1-2 degrees angle and is actuated by the usual foot pedal, permitting the use of a 450-pound clutch spring, and so designed as to give perfect alignment. The clutch is fitted with a ball spring thrust and a ball clutch thrust. The gear box, like the motor, is mounted on a sub-frame and provides three speeds and reverse, with selective type of change speed lever. All gears and shafts revolve on annular ball bearings, which reduce the loss of power due to friction to a minimum. A double universal joint between the motor and transmission insures perfect alignment.

Drive is by cardan shaft to rear live axle, of the Timken type, fitted throughout with Timken adjustable roller bearings. The pinion and pinion shaft are supported by two cages of adjustable roller bearings, which insure constant and perfect alignment between the pinion gear and the large bevels on the differential. A four spur standard type differential is used, the hub of which is broached to accept the squared ends of the floating type driving axles. On the outer ends of the driving axles are machined square ends, to which are attached driving jaws or clutches that engage similar jaws in the rear wheels. This, the stand-

AS THE PENNSYLVANIA LOOKS FROM THE REAR.

ard type of floating rear axle, embodies every improvement and is built of such material that it is of greater strength than the possible power developed by the motor. The gear mechanism is controlled by a single lever traveling in a H-slot guide, with the piston interlocked between the low and the reverse to prevent any possibility of going into reverse while the car is moving forward.

Brakes.—Two independent braking systems are provided, both operating on drums on the rear road wheels. The foot brake controls a contracting band on the drums, and the side lever operates the expanding internal brakes on the same drum. A unique system is employed to equalize both the foot brake and emergency brake on the rear wheels by means of a link pulling forward from the center of a yoke, which contracts and expands the two bands.

The machine has a road clearance of 9 1-2 inches, and under the motor and transmission gear is a fiber mud pan completely protecting all working parts. It is suspended by means of eccentric clips, and so arranged that it can be dropped in a moment by releasing the clips.

For the touring car the accommodation provides seating for five people, three in the tonneau and two in the front. The body is large and roomy, well upholstered and finished in either Brewster green or Mercedes red. A complete equipment is provided, consisting of tools, gas and oil lamps, generator, horn, etc., and the total weight is 2,700 pounds.

The runabout, known as Model 8, is a racy-looking machine having the same power plant as on the touring car just described but four inches shorter in wheelbase and with the front wheels carried directly under the radiator. The runabout body provides the two usual seats and has, in addition, a folding rumble seat in the rear. A movable trunk is also provided as a part of the regular equipment. This car weighs, complete, 2,200 pounds and is geared 2 1-2 to 1.

Pennsylvania Makes Fast Economical Run.

An interesting demonstration was recently made by the new Pennsylvania car in a run from the factory at Bryn Mawr to Nutley, N. J. The cyclometer registered 116 miles, and this distance was covered on 6 1-2 gallons, which gives an average of 17.7 miles to the gallon. The total distance was covered in six hours, from which must be deducted 50 minutes lost for two meals, giving an actual running time of 5:10, or an average speed of 22.4 miles an hour.

FOR AMERICANS TOURING IN AUSTRIA.

Consul J. S. Twells, of Carlsbad, furnishes the following report on the regulations governing foreign automobilists in Austria:

During 1906, April to November, a large number of American automobilists visited this consular district, in which the well-known Austrian watering places of Carlsbad, Marienbad, and Franzenbad are situated, and as scarcely any owners of machines were acquainted with the regulations in force regarding foreign automobilists, great inconvenience was experienced by many Americans. They thought themselves justified in submitting their grievances to the authorities, hoping to get relief. As the number of Americans coming to this district is likely to be even greater during 1907, travelers using automobiles should make themselves acquainted with the legal rules and regulations now in force, because those who do not understand them may find themselves subjected to disagreeable positions and meet with many troubles and annoyances which could be avoided. The following is an extract from the rules and regulations in regard to automobiles coming into Austria:

For every automobile passing the frontier, no matter whether the automobile remains in the country or not, and without any reference to the machine being old or new, or for private use or business purposes, the full custom-house duty levied must be paid in cash if the machine remains in the country, or the amount is requested to be deposited if it is to be taken out of the country. It is very important that travelers should provide themselves with sufficient Austrian money before they enter the empire.

A duty must be paid or deposited for machines weighing 800 pounds, \$15 per 100 pounds; from 800 to 3,600 pounds, \$12 per 100 pounds; from 3,600 to 6,400 pounds, \$10 per 150 pounds; and above 6,400 pounds, \$8 per 150 pounds. When producing the receipt on leaving the Austrian Empire the money deposited will be returned to the owner. A machine brought into Bohemia may be used fourteen days without restriction. After that time the use is only permitted if it has been subjected to a technical examination by a commission appointed by the chief court of administration at Prague. A tax of 120 crowns (\$24.36) is required to be paid for this examination. Machines coming from certain countries with which the Austrian Government has made a special agreement, as for instance, Bavaria, Italy or Saxony, can be used without an examination three months.

All persons driving motor cars in Bohemia longer than eight days must undergo an examination at Prague or Reichenberg to obtain a license, for which a tax of 50 crowns (\$10.15) has to be paid. Drivers from Italy may drive three months without any examination or license. The speed of a car must never exceed 9 miles an hour in towns and villages or 28 miles on the highroad; during a fog, at crossings, curves, and in all places where special care should be exercised, the speed must not exceed 3 1-2 miles. In inland towns and villages it is not permitted to drive with an open exhaust box.

POWER PLANT OF THE 35-40 H.P. PENNSYLVANIA CAR AND ITS CONTROLLING MECHANISM.

UNDER the title of the "Blomstrom Thirty" one of the most promising entrants of the medium-priced field that the market has brought forth in many a day, is making its debut this season. Though it is thus a debutante, its newness is that of name alone, for from bonnet cap to rear axle it is the product of ripe experience. C. H. Blomstrom, who is its sponsor, was the designer and originator of the Blomstrom "Queen" cars, of which more than a thousand now grace the roads in various parts of the country. They first made their appearance on the market in 1902, and then represented the culmination of many years knowledge gained in practical gas engineering. They were of the horizontal opposed type, then a standard design in this country, and in the course of evolution they were followed by a four-cylinder vertical model, of which several hundred were marketed last year. In the interim, Mr. Blomstrom has become identified with the Blomstrom Manufacturing Company, of Detroit, Mich., in no way connected with the former C. H. Blomstrom Motor Company, and has devoted himself to turning out what may well be termed his best effort in this line.

Motor Design.—The new car is not alone extremely attractive so far as what the Frenchman is pleased to term its *tout ensemble*, but its power plant embodies features of design and construction that reflect the experience of its creator and show how well he has profited, not alone by his own knowledge in this direction, but by the mistakes of others in this field. To put it briefly, the motor is representative of standard practice in every detail; there has been no attempt whatever to depart from accepted and well-proven lines, nor to introduce anything whatever of a radical nature. Reliability and endurance have been the watchwords of the designer throughout, and to this end simplicity and accessibility have been sought

for, not without a goodly measure of success, as will be apparent from the view of the complete motor from the carbureter side, which is shown here. The cylinders are cast in pairs from the best grade of iron especially selected for the purpose and measure 4 3-16 by 4 1-2-inch bore and stroke, respectively, the motor developing its rated output at 1,000 r. p. m. The valves are mechanically operated and oppositely disposed; this arrangement, though it necessitates the use of two separate camshafts, is favored by the designers of many of the best known and highest-priced cars on the market, both of American and foreign build. In fact, for a car designed to be placed on the market at such a low figure, the Blomstrom Thirty contains not a few features usually to be found only on very much higher priced cars.

Motor Accessories.—For ignition, the high-tension system is employed, using accumulators as current supply with dry cells in reserve, the spark plugs being placed directly over the inlet valves. The position of the low-tension ignition timer is at once noticeable as differing considerably from current practice in this respect. It is placed horizontally near the forward end of the motor and is on a short shaft extending out a little distance from the motor, making it very accessible. It is driven by miter gearing from the camshaft, while the circulating pump of the gear type is driven direct from the camshaft gear. The pump is also in a very accessible location, as it is placed much higher on the motor than is customary, being raised well above the level of the bottom of the cylinders. The carbureter has also been placed high, it being quite evident that the designer has borne the matter of accessibility in mind at all times. The neatness and simplicity of the inlet manifold is particularly striking, as will be noted from the illustration showing the carbureter side of motor. All gears are housed.

CARBURETER SIDE OF MOTOR, SHOWING TIMER.

Change Gear and Drive.—The clutch is of a novel design, of Mr. Blomstrom's own creation, and is distinguished by its simplicity. It consists of a complete circle male member fixed rigidly to the flywheel; this carries a raised V of substantial dimensions and the corresponding groove of the clutch in the movable portion consists of three grooved faces on a fixed and a moving member. One, the front angular piece, is integral with

END VIEW SHOWING NEW CLUTCH.

the clutch, while the rear wall groove is detached and has two angular faces, one engaging the rear side of the male V, and one arranged to slide forward on an angular surface of the clutch body. This detached triangular rear wall groove is subdivided into four segments, each of which is pushed forward by a toggle action from the sliding clutch member, so as to cause it to wedge between the inclined rear face of the male member and the rearward facing cone seat on the clutch body itself. It would seem from the description that the device is quite complicated, but the complication lies rather in the language necessary to convey an idea of its working rather than in the apparatus itself—a fact that will be plain from the rear view of the motor, showing the clutch complete and in place on the flywheel. In use it is inclosed by a light casing fastened to the flywheel.

The change speed gear is of the sliding type, all of the pinions being of special nickel steel and hardened. Shifting is selective by means of one lever in a single wide slot, rocking laterally in order to engage either the inner or outer concentric rocker and sleeve rocker arms, giving the different speeds; the gear-shift and the clutch-rocker not being interconnected. The construction of the clutch permits it to serve the double rôle of clutch and universal joint, so that the necessity of a universal between the former and the change speed gear box has been eliminated. A universal is interposed between the rear end of the lineshaft and the forward end of the driving shaft, neither torsion nor strut rods being employed. A bevel gear drive is fitted together with a spur pinion differential.

Running Gear and Suspension.—Weston-Mott axles are employed, the front wheels running on two-point ball bearings and the rear on Hyatt roller bearings. The rear wheels are keyed to the tapering ends of the live axle, forced home and held in place by hexagonal nut retainers. Having so successfully demonstrated the value of the full-elliptic spring on the Queen cars, Mr. Blomstrom has retained them in this case on the rear with semi-elliptics in front. In each case they are 38 inches in length and have five leaves.

General Details.—The steering gear is of the worm and

HOW THE BLOMSTROM "30" RUNABOUT SHOWS UP.

sector type, irreversible, and is designed to be free from backlash. The running brake is pedal operated and consists of a toggle expanded bronze shoe engaging the inner surface of the steel brake drum on the driving wheels; the emergency, which is of the contracting type, also consists of a bronze shoe engaging the outer face of the same drum; it is interconnected with the clutch. The running brake bands are faced with camel's hair belting, while the emergency is metal to metal, *i.e.*, steel to bronze. The wheelbase is 110 inches, the tread standard, and the tires on all four wheels are 32 by 3 1-2 inches. The body design is of the straight-line type, the outline of the bonnet being made to conform so that the car as a whole presents a most attractive and businesslike appearance. Every feature of the car shows that it is the product of a designer who has been through the mill and is fully conversant with what is required to make a car that will be not alone attractive and reliable, but enduring as well, and when a machine combines these three essentials there is nothing further to be said.

PROGRESS OF THE MARINE GASOLINE MOTOR.

According to *Engineering*, the movement for propelling trading vessels of moderate size by internal combustion engines of one type or other—suction gas, petrol, paraffin, etc.—has not been very materially advanced during the year by anything actually done in this country, but on the Continent various partially successful, and on the whole very promising, trials have been carried out. On the Clyde the firm of Beardmore continue to experiment with engines of the Capitaine type using producer gas, and this year, no doubt, definite progress will be made. A small trading vessel, motor-propelled, and carrying some 200 tons, has been running for some time between Swansea and Avonmouth, and the Ailsa Shipbuilding Company, of Troon, has on hand for MacBrayne's, of Glasgow, a vessel of 100 feet in length, to be propelled by motor, and do trading service in the West Highlands. Of course, for pleasure and tender services motor boats are now a common product, and marvellous results are being attained by Thornycroft, Yarrow, White, and the other noted builders of such craft. Motor vedette boats are now being built for the new Dreadnoughts, which are 51 feet over all, and it is estimated that an internal combustion engine, specially constructed to work with the same fuel as in the battleship boilers, of 250 horsepower, will give the same results, as to speed and its cost, as the steam engines and boiler of 350 horsepower which would otherwise have been installed. For the successful motor engines which home firms are now turning out in great numbers, this country has, no doubt, largely to thank other countries. Both in German and Dutch waters steam has been almost entirely superseded.

AUTOS TO HELP SOLVE SERVANT PROBLEM.

Automobile lunch wagons, not the ordinary kind of horseless carriage that has become familiar through its years of service connected to the pavement by water and gas mains on city street corners, but something new in this line, are to be called upon to help solve that bane of all suburban communities—how to keep Bridget. Biddy and all her ilk are to be communized—not on the Sinclair plan or anything similar; they are simply to be boiled down into a central power station, so to speak, from which shall emanate cooked dinners, clean laundry and the other comforts of life according to a schedule. A certain Mr. Robinson, of Montclair, N. J., where the question of having a Kate or Bridget during the cold months becomes exceedingly acute each year, is responsible for the idea. Things have been so bad there this winter that many of the inhabitants were compelled to migrate to the joys of urban hotel life. Hence Mr. Robinson's co-operative plan, which as its *pièce de résistance* includes hot dinners delivered by auto. Whether a waitress is delivered at the same time to serve them does not appear.

SPEEDY REPRESENTATIVE OF THE KLINK LINE

OWING to the demand that was experienced for the Klink car last year, its makers, the Klink Motor Car Manufacturing Company, Dansville, N. Y., have found it necessary to greatly enlarge their facilities at the opening of the second year, and have accordingly increased their capital stock to \$400,000. For the coming season their line consists of a 45-horsepower 7-passenger touring car, a 30-horsepower 5-passenger touring car and a 30-horsepower roadster or runabout, which is pictured at the head of this page. A modern plant has been erected and equipped with every facility for turning out cars at a rate to keep pace with their scheduled delivery dates.

As there is a large call for the runabout type of car, particular attention will be paid to this end, and as will be at once apparent from the illustration, the design is along very attractive and speedy lines, while the proportion of power to weight is high. The motor is of the four-cylinder vertical type of standard design and construction; its dimensions are 4 1-4 inch bore by 4 3-4 stroke, all valves being mechanically operated. A great deal of attention has been paid to obtaining a perfect balance in the motor, so that the latter is unusually quiet-running. The entire power plant is supported on a sub-frame consisting of two substantial transverse members attached to the side members of the main frame, which is of pressed steel and of the usual channel section. An automatic float-feed carbureter takes care of the essential of fuel supply, while the ignition is of the high-tension order, employing a set of accumulators as the source of current supply, with dry cells for reserve. A honeycomb radiator of attractive outline forms the chief essential of the cooling system, the water being circulated by a gear-driven pump. A mechanically-driven force-feed oiler takes care of the lubrication.

The change-speed gear is of the sliding type, progressively operated, and provided with three speeds forward, *et marche arriere*, as the Frenchman puts it, though it seems entirely superfluous nowadays to mention that a car has a reverse gear—almost as much so as it would be to remark that it ran on four wheels. The pinions are of nickel steel. Final drive is by propeller shaft and bevel gearing. Anti-friction bearings are used in many instances, the shafts of the change-speed gear being mounted on roller bearings, as are also the rear wheels, while the front wheels run on ball bearings. As has come to be recognized standard practice, two independent sets of brakes are employed and both are centered on special brake hubs on the driving wheels. They are of the internal expanding and external contracting type, the latter being interconnected with the clutch.

Control is by means of the usual throttle and spark levers, mounted on a stationary sector above the steering wheel, an accelerator pedal also being provided for the former, thus permitting the car to be speeded or slowed down independently of the position of the hand lever, this expedient being found particularly convenient for driving in crowded street traffic. The positions on the quadrant of the change-speed gear lever are plainly marked, so that it is impossible for the driver to shift too far one way or the other in changing up or down. The steering gear is of the irreversible type and no pains have been spared to obtain the required rigidity and certainty of action in this highly important part of the car.

Suspension is by means of semi-elliptic springs of approved type and of the best spring steel, both front and rear; the latter are 50 inches long by 2 inches wide and have 8 leaves, while the former measure 42 inches in length and have but 6 leaves, the width being the same as the rear springs. The wheelbase is 108 inches and the tread standard. As shown in the illustration, the runabout type is provided with a special design of mudguards, which give perfect protection at all speeds. Equipped with two bucket seats, and a rear or "tiger" seat, as well as the usual outfit of lamps and other similar accessories that go to complete the car, the 30-horsepower Klink runabout lists at \$2,000, 32 by 3 1-2 Goodrich quick detachable tires being regularly supplied.

Using the same chassis throughout, and with a touring body having comfortable capacity for five passengers, the Model 30 touring car is constructed so that the foregoing description applies to the latter, with the exception of the body details. The weight all on in the case of the runabout is 1,950 pounds, while the touring car in complete running order tips the scales at but a scant 200 pounds additional, or about 2,100 pounds, which makes the ratio of power to weight unusually favorable in either case and permits the negotiation of anything but unusual grades on the high gear. Dansville, the home of the Klink, is situated in a picturesque valley in upper New York State, and is surrounded by hills affording grades to try the mettle of the best of cars. It is here that the output of the Klink factory undergoes its final trying out before reaching the purchaser's hands, so that its ability in the matter of both hill-climbing and getting over the rough roads for which this country is notorious is well established before it leaves the builders. Both the 30 and 45-horsepower chassis have been designed with a liberal allowance of power for their weight, as well as with ample road clearance and springs meant for traveling over the usual American roads.

A KENTUCKIAN'S RUN INTO ADJOINING STATES By C. M. Shepherd

THE automobile "contagion" had become permanently settled on the south side of the Ohio river, and I was one of the first to contract the fever. Not being content with short jaunts, a desire followed for a long tour, and in the early part of July arrangements were made for a run through Illinois and Indiana. With a party of four, we set out from Owensboro, reached Evansville, Ind., and had a pleasant run to Princeton. From this point we proceeded in the direction of Vincennes, and on leaving Princeton we crossed the "trouble line" in reality, for we received the usual batch of Indiana-ians misdirections and were successfully piloted into a twenty-five mile stretch of newly-made mud road which had just received a baptism of rain, had no bottom, and appeared to have no end either. Had there been a railroad station available we would gladly have shipped our car and given up the trip, for I expected every stroke of the engine to be its last. On we plodded until at last a commutator spring broke in two, and we were persuaded that we should have to apply for horsepower of another variety.

The trouble was soon located, but might not have been as rapidly remedied had not the lady of our party suggested and supplied corset steel. It answered its purpose well, remaining in use until we reached Rutland, Ill. After having plowed many miles of Indiana mud on the low gear, Terre Haute was reached early in the afternoon. During this tour the White river was crossed at a charge of \$3.50; a two-horse team and wagon load of corn was transported for the sum of fifty cents.

Through the Central Counties of Illinois.

The Wabash river was crossed at Terre Haute and our course directed toward the northwest, where we were soon to enter the State of Illinois. Road conditions were fair, except near Bloomington, Ill., where heavy rains and constant traffic had spoiled the surface. There was a notable difference, too, in the attitude of farmers and horse drivers in Illinois compared with those in Indiana. If an Illinois man's horse becomes frightened he attributes the blame to the animal and not to the machine. These conditions are fast changing, and the time will soon come when the horse will have a familiar neigh for the auto.

Fifteen days were spent with Rutland as headquarters, a number of short jaunts being made to neighboring towns. A pleasant visit was made to the historic Deer Park and Starved Rock, a distance of twenty-five miles north of Rutland on the

Illinois river, where we picknicked, used the camera and enjoyed the natural beauties of the place. There is excellent hotel accommodation here, and thousands of people visit the spot every year. The return journey was planned through Bloomington, Champaign, Danville, Crawfordsville, Indianapolis, Columbus, North Vernon, Scottsburg, Salem, West Baden, French Lick, Jasper, Huntington, and south to Rockport. We left Rutland at five in the morning, and tied up at New Ross, 185 miles distant, at 6.30 in the evening. The country thus far was level and the roads in excellent condition. We bowled along, the engine let out to its full capacity, and finished a magnificent run with nothing heavier on our consciences than the death of a few fowls, which, fowl-like, would stand in the road until we were within a few feet of them, then make a wild dash for the side.

Back Again to the Hoosier State.

We were speeding south over excellent roads, the following morning, in the direction of the auto city of Indianapolis, which we reached in the early forenoon and quitted in the early evening to continue to Edenburg, where we had an appointment for the night. North Vernon, our next scheduled point, was reached at nine o'clock in the morning by the Michigan-Indiana State road, which runs from Michigan City to Madison, Ind. Near North Vernon the road was blocked by a long procession of spring-wagons, surreys, buggies, and jolt-wagons, en route for the Jennings county fair. We were anxious to go ahead of the procession, but they, on the other hand, had different views, and kept us in the rear of the snail march for three or four miles, at times driving three or four abreast to keep us behind. Finally we got through and gave them a taste of our dust as we speeded away.

Early on the fourth day we moved southward by the way known as Nigger Hills, parts of which are unknown to the autoist, and which may be described as of the "bumping the bumps" order. This condition continued for about seven miles south, then fair roads reappeared and continued into Scottsburg. Turning due west from Scottsburg we were soon on the "trouble line" again. Roads of stone, gutters of dust, and apparently river beds of rock, with hills such as we have never looked upon east of the Rocky Mountains, were now our lot. At the foot of each hill was a bad culvert, which made coasting an impossibility. At the close of the day we anchored at Salem, Ind., a picturesque village on the summit of the noted Salem hill, where excellent hotel accommodation was secured.

In the Unfrequented Nigger Hills.

Refreshed and joyous, we speeded westward the following morning, little dreaming that the worst was yet to come, and that the roads we had traveled over were macadam compared to those which lay before us. Not only were they unknown to the automobilist, but they did not bear the slightest evidence of ever having been used by the ordinary vehicle. Large boulders, which might have been straddled by a high buggy, filled the center of the track. While we were zigzagging round these obstructions we were informed by natives that we were approaching Pots Hill, a point that an automobile had never been known to pass without the assistance of a team. The natives had not exaggerated, but we got through under our own power, although the car is only a single cylinder machine, a Cadillac model M.

It is impossible to give an adequate description of the road conditions about this district. All that can be said is "beware of the Nobs." We touched numerous small villages in which our car was the first that had ever been seen. Excitement was great, and we heartily enjoyed watching the actions of both young and old, eager to lay their hands on the machine.

The road conditions mentioned continued well into Jasper, where we turned abruptly south, leaving the Indian Rockies far in the rear, and experienced smooth sailing into Rockport, Ind., where we took the ferry across the Ohio and reached Kentucky soil with a full knowledge of a little travelled route and a resolution to give it a wide berth on our next trip to the North.

FIVE STATE BODIES ADDED THE GROWING A. A. A.

THE A. A. A. continues to increase and prosper under the energetic efforts of the Hotchkiss-Elliott administration, and in the past ten days five State associations have been added to the national roster: Pennsylvania, Maryland, Kentucky, Indiana and Missouri. Michigan and Wisconsin are additions of the early future.

The A. A. A. list now contains twelve State bodies: Massachusetts, Connecticut, New York, New Jersey, Pennsylvania, Maryland, Ohio, Indiana, Illinois, Minnesota, Kentucky and Missouri. The Rhode Island Automobile Club in Providence is to become shortly the nucleus of a State organization; Vermont is a "soon" probability, and Michigan and Wisconsin are sure. At the next meeting called by President W. H. Hotchkiss the Executive Committee may have a dozen applications to act upon, and the total number of State bodies may reach a score or more. Apparently the retention of the greater part of the dues and the conduct of affairs in their own borders is responsible to some degree for the rapidly increasing number of State associations.

Maryland Now Has Its State Body.

BALTIMORE, April 15.—Desiring to obtain better conditions in automobiling, the Automobile Club of Maryland and representatives from the various other clubs throughout the State met last week and formed the Maryland State Automobile Association of the American Automobile Association.

The meeting was presided over by H. M. Rowe. Secretary Frederick H. Elliott of the A. A. A. was present and spoke at length upon the benefits to be gained through State associations and membership in the national organization.

After the new association had been formed by a unanimous vote, Osborne I. Yellott spoke on the practicability and feasibility of establishing a legal bureau for the State association. Subsequently it was decided to appoint a legal bureau, to be supported by a small assessment upon the members, whereby counsels will be stationed in almost every town to render service to autoists who are unfairly arrested for alleged non-observance of the speed laws. Each member will carry a card of identification, which will be the medium to secure immediate representation of belated motorists wherever they may be detained, since the State association will guarantee a fee to any lawyer who defends one of its members.

Pennsylvania Motor Federation in the A. A. A.

PITTSBURG, PA., April 15.—At its recent annual meeting, held at the clubhouse of the Pittsburg Automobile Club, the Pennsylvania Motor Federation unanimously decided to affiliate with the A. A. A. President W. H. Hotchkiss was present by special invitation and the forcible and convincing address which he made was a factor in the decision to become a part of the national organization. The Federation contains fifteen of the twenty-one clubs in Pennsylvania, and those outside of the breastworks are likely members of the near future.

These were the clubs and delegates represented in the annual meeting: Isaac Starr, president Automobile Club of Philadelphia; Robert Hooper, president Automobile Club of Germantown; F. R. Slifer, Milton Automobile Club; Paul C. Wolff, Dr. J. C. Hawkins, Pittsburg Automobile Club; John C. Gragdon, representing Pittsburg Consulate, A. M. L.; Dr. W. G. Cook, Wilkesburg Automobile Club; Jacob Rider, Lancaster Automobile Club, and A. H. Martin, the Automobile Club of Delaware county.

In the election of officers the result was as follows: President, Isaac Starr, Automobile Club of Philadelphia; first vice-president, Robert P. Hooper, Automobile Club of Germantown; second

vice-president, F. R. Slifer, Milton Automobile Club; secretary, Paul C. Wolff. The latter was active in the formation of the Federation.

The committee chairmen announced were: Good Roads Committee, Peter A. Meixell, Wilkes-Barre Automobile Club; Legislative Committee, S. Boyer Davis, Automobile Club of Philadelphia; Touring Committee, State Senator Godcharles, Milton Automobile Club; Publicity Committee A. H. Martin, Delaware County Automobile Club. These committees will be organized by the selection of a member from each club of the Federation. Messrs. Starr and Hooper have been particularly energetic in bringing about the affiliation of the Federation with the A. A. A. Mr. Hooper is chairman of the A. A. A. Good Roads Board, and intends that his board shall work industriously for Government aid in roads building.

Kentucky's Leading Club Joins the A. A. A.

LOUISVILLE, KY., April 15.—At the annual meeting and banquet of the Louisville Automobile Club, held at the Louisville Hotel, George H. Wilson for the fourth time was elected to the presidency of the club, which unanimously decided to join the A. A. A. and at once organize a Kentucky State Association of the national organization. Secretary F. H. Elliott and Executive Committee member A. G. Batchelder of the A. A. A. were present and made addresses.

In addition to re-electing Mr. Wilson, the club selected for first vice-president Dr. W. C. Pfingst; second vice-president, Pike Campbell; secretary, Charles Chreste; treasurer, J. B. Lewman. The club is arranging for a tour of the bluegrass section of the State, held for the purpose of interesting Kentucky automobilists in the State body.

Hoosiers in the A. A. A. Procession.

INDIANAPOLIS, IND., April 15.—The Indiana State Automobile Association was born last Friday night at an enthusiastic meeting called by the Indiana Automobile Club and held at the Columbia Club in this city. The delegates present were: Indiana Automobile Club, President P. E. Hibben, H. O. Smith, R. A. Brown, R. J. Eads, George A. Weidley, F. N. Ayers, George W. Pangborn, H. H. Rice, L. H. Levey; Kokomo, Edgar Apperson; Richmond, J. A. Speckeneher; South Bend, Horace Kizer, M. L. Williams, Mr. Briggs.

The election of officers resulted as follows: President, H. O. Smith; first vice-president, John Cox, Terre Haute; second vice-president, Horace Kizer, South Bend; treasurer, J. A. Speckeneher, Richmond; secretary, Edgar Apperson, Kokomo.

It had been expected that coincident with the meeting would be a session of the leading engineers of various automobile concerns for the purpose of drawing up rules for the stock car race over the Long Island Motor Parkway in October next. A. G. Batchelder, member of the A. A. A. Racing Board, and also of its Executive Committee, informally discussed rules for such an event with Messrs. Smith and Apperson and others. It is expected that the postponed conference will take place in the near future. Secretary F. H. Elliott was present in his official capacity and convincingly explained the worth of a national organization and the general good it accomplishes for automobiling.

Missourians Were Shown by Secretary Elliott.

ST. LOUIS, Mo., April 15.—The Missouri State Association of the A. A. A. has been organized by the election of Harry M. Rubey of the Macon Automobile Club as president and Roy F. Britton of the St. Louis Automobile Club as secretary-treasurer. Secretary F. H. Elliott of the A. A. A. was present at the session, which was held at Macon, about midway between St. Louis and Kansas City. Mr. Rubey is the Mayor of Macon.

AUTO CLUB DOINGS FAR AND NEAR

Joint Orphans' Day Run Projected in Chicago.

CHICAGO, April 15.—At the last meeting of the directors of the Chicago Motor Club it was decided to observe the National Orphans' Day, June 12, which was recently instituted by the A. A. A. The club appointed a committee consisting of N. H. Van Sicklen, chairman; Fred E. Dayton, L. J. Ollier, J. V. Lawrence and Harry P. Branstreter to confer with the Chicago Automobile Club and Chicago Automobile Trade Association with the view of making the celebration of the day a general one among automobilists of the city.

The new \$165,000 clubhouse of the Chicago Automobile Club is rapidly approaching completion, and it is confidently predicted that it will be practically ready for occupancy by May 30. President Cobe, in speaking of the progress made, states that he is more than confident that the club will take possession by Memorial Day. "The contractors are now making very rapid progress," he says, "and unless some unforeseen incident bobs up our patient members who have been homeless so long will find a roof to cover them at 15 Plymouth court in a little more than six weeks. As soon as we get in there we will start doing something. The Glidden tour is of great interest to us and the Chicago Automobile Club is going to hold up its end in the entertaining line when the tourists reach this city for their Sunday stop. We are going to have a special committee to look after the entertaining, but I will not appoint it for a while, because it is some three months off, that tour.

"We are taking in about a dozen new members every meeting. Ten were admitted yesterday and now our list is almost full. You know we have a waiting list at 600, and, while I don't know positively, I believe there are only about a dozen vacancies left."

Vermonters Organize Automobile Club at Rutland.

RUTLAND, VT., April 8.—An organization to be known as the Rutland Automobile Club was formed in this city April 6. The following officers were elected: President, William H. Riddle; vice-president, Percival W. Clement; secretary, Charles A. Matthews; treasurer, Wallace W. Nichols. Committees on nominations and by-laws were also elected and a board of governors, of which Gov. Fletcher D. Proctor is chairman. William R. Riddle, of this city, a member of the Touring Committee of the American Automobile Association, was chiefly instrumental in organizing the club, which is the first local association to be formed in Vermont. It is expected that the membership will be about fifty. The object of the club will be to promote interest in the sport, foster the good roads movement, and compel careful driving on the part of its members.

New Club of Sixty Members at Akron, O.

AKRON, O., April 12.—The directors of the Akron Automobile Club have organized by electing the following officers: President, C. C. Goodrich, of the B. F. Goodrich Company; vice-president, Andrew Auble, of the Akron Automobile Garage Company; treasurer, A. B. Rinehart, of the Union Garage. The club will have headquarters and clubrooms, and it expects to make a persistent fight for good roads and favorable ordinances for the use of the city streets. About sixty members have been enrolled.

Kentucky Autoists Organize a Club at Paducah.

PADUCAH, KY., April 15.—Seventeen leading automobilists of this city have organized the Paducah Automobile Club and elected the following board of officers: President, P. D. Fitzpatrick; vice-president, F. E. Lack; secretary, Roy Grassham; treasurer, Richard Ruddy. In addition to the above-named officers Benj. Weille and Samuel Foreman constitute the board of directors.

Monk's Hill Selected for the Quaker City Climb.

PHILADELPHIA, April 15.—Monk's Hill, a tricky, sticky-in-wet-weather, mile-long grade leading up out of the Schuylkill valley at Gladwyne station, on the Philadelphia & Reading railroad, has been finally decided upon by the contest committee of the Quaker City Motor Club for its Decoration Day hill club. Besides a none-too-good surface and an average 20 per cent. grade, Monk's Hill possesses all the requirements of the modern hill-climbing course, including thank-you-ma'ams and the inevitable "elbow"—though this time his Satanic majesty and the hairpin have been sidetracked in seeking a name for the sharp loop and the name "Quaker" substituted. The "Quaker's elbow" will furnish an ample test of a driver's ability in negotiating a fast-running car up its slope, while those who contemplate "rushing it on the high" will in all probability be considerably wiser before they reach the top.

Located less than ten miles from the clubhouse, the course may be reached by the most direct route in 20 minutes, while with the Reading station within a few hundred yards of the start spectators can be landed there within 15 minutes from the Reading terminal. Besides, in selecting this hill the contest committee has neatly solved the traffic problem, for the road is seldom used and a permit will hardly be required.

Site for Grand Rapids Club House Selected.

GRAND RAPIDS, MICH., April 15.—The Grand Rapids Automobile Club has settled the matter of a new clubhouse, and at a special meeting of the club a committee was selected to secure a site at Cascade Springs. At the meeting a committee was also appointed to investigate the matter of paying toll on toll roads. The club will fully determine the rights of automobilists in that direction. It has been suggested that the automobile owners of Kalamazoo form a club and that the two clubs then combine with a clubhouse midway between the two cities, but this plan is not finding much favor.

Annual Tour of the Albany A. C. Set for June 20.

ALBANY, N. Y., April 15.—Atlantic City, by way of New York and Asbury Park, is destination and route chosen for the annual tour of the Albany Automobile Club which is scheduled for June 20. Last year the club tour was through the Berkshires to Boston. At the last meeting of the club five new members were elected, and resolution was adopted requesting the city authorities to instruct its police officers to enforce the observance of the rules of the road upon both drivers of automobiles and horses for the greater safety of the traveling public.

Newark Club Nominates Officers.

NEWARK, N. J., April 15.—At the last meeting of the board of governors of the New Jersey Automobile and Motor Club, Angus Sinclair was nominated for president of the organization. The Board of Governors also placed in nomination Louis T. Wiss as president to succeed Mr. Sinclair, who has occupied that position for the past year; James C. Coleman as treasurer, H. A. Bonnell as secretary, and Joseph H. Wood, W. F. Kimber and W. C. Crosby as trustees. The regular election of officers will take place at the annual meeting of the club on May 6.

J. C. McCoy Elected Vice-President of the Aero Club.

NEW YORK, April 15.—At a meeting of the Aero Club of America held last week J. C. McCoy was elected vice-president in place of Homer W. Hedge, who resigned both as vice-president and director. Ten new members were added to the rolls. It was decided to accept the trophy offered by the *Scientific American* for aeroplanes, the first contest to be held at Jamestown.

THREE FRENCH AEROPLANES HAVE FLOWN

PARIS, April 7.—Santos-Dumont has a serious rival in Léon Delagrangé, the French sculptor with aeronautical tendencies. On the Bagatelle polo ground a few days ago, M. Vuia had interested the idlers by giving displays of short flights with his little machine, when Delagrangé asked Charles Voisin to make a run. There were few people about, the ground being particularly free for experimental flights. A couple of false starts were followed by a flight of about twelve yards to windward, the machine heeling over slightly. To establish equilibrium Charles Voisin fixed a weight on one of the wings, mounted the cage,

in idleness, but on the end of the third day, the weather being fine and ground fairly hard, preparations were made for what might have been an epoch-making event. Santos-Dumont ordered his machine out, climbed up into the cage, started his motor, and in less time than it takes to tell was rushing down the drill ground. Thirty yards away the *Bird of Prey* rose six or seven feet in the air, rushed on for sixty or seventy yards, rolling dangerously, finally touched the ground with the right wing, capsized and came to a stop. All this had taken place within a few seconds, thrilling seconds for the spectators, who

realized the danger to which the air pilot was exposed. Before the little group could reach the wrecked machine Santos-Dumont had extricated himself and shouted out that there was nothing the matter. On a closer examination it was surprising to find that there was so little damage; one wing was broken, a road wheel was smashed, but the motor and transmission were intact. In three or four days all will be again ready and another permanent deputation will be sent from the Aero Club to Saint-Cyr.

It is just possible that the accident may cause Santos-Dumont the loss of the \$10,000 prize, for three other aeroplanists are ready to attempt the kilometer circuit, among them being Léon Delagrangé, whose machine has already flown seventy

yards in excellent style. The prize goes to the one who first fulfils the conditions set for the contest.

St. Louis Secures Lahm's Famous Balloon.

The *United States*, the balloon in which Lieutenant Lahm won the Gordon Bennett aero cup last year from Paris to the North of England, has been sold to the Aero Club of St. Louis and will be refitted immediately. J. C. McCoy, who has been elected vice-president of the Aero Club of America, and will be the executive head of the organization after Cortland Field Bishop sails for Europe on April 18, expects to try to win the Lahm cup by making a flight of more than 402 miles from St. Louis the latter part of this month. Mr. Hawley will make an ascension soon afterwards.

DELAGRANGE AEROPLANE FLYING TO WINDWARD OVER BAGATELLE GROUND, PARIS.

started up the motor, and in a few seconds was running down the field toward the racecourse, wind still ahead. After about one hundred and fifty yards sprint on the ground the machine rose fourteen feet in the air and covered a distance of 65 yards at a speed of thirty-six miles an hour. A cheer rose from the little group of enthusiasts watching the experiments, and Voisin, surprised and delighted, momentarily forgot himself and cut out his ignition. The machine gently descended to Mother Earth, uninjured and ready to begin again. It is certain that had Voisin left his engine running his machine would have traveled to the end of the polo ground in perfect equilibrium. Santos-Dumont, who was present, warmly felicitated Voisin and Léon Delagrangé, and declared that there was nothing whatever to prevent a continuance of the flight. There are now three aeroplanes in France which have made successful public flights: the Santos-Dumont *Bird of Prey*, the Vuia and the Delagrangé machines. This latter, which has been built by the Voisin Frères, of Billancourt, Paris, has a 50-horsepower Antoinette motor with eight cylinders forming V and direct induction feed without carbureter. The superficial area of the machine is 60 square meters, weight 660 pounds, with rear propeller of 90 inches diameter, and a rudder forward.

Santos-Dumont Resolved to Win Aero Club Grand Prix.

Since the breaking of his new aeroplane, Santos-Dumont has brought out again his *No. 14 bis*, with which he won the Archdeacon prize for a flight of 240 yards, and has been making further experiments. Propelled by the 50-horsepower Antoinette motor, the machine has given such satisfaction that its proprietor has decided to attempt to win the \$10,000 Deutsch-Archdeacon prize for the first aeroplane covering a circuit of one kilometer. Three days were fixed, and a deputation was sent from the Aero Club of France to remain at Saint-Cyr from sunrise to sunset, as specified in the regulations. April showers, alternating with March winds, caused the two first days to be passed

HYDROPLANE TESTING AERIAL PROPELLER ON SEINE.

The hydroplane shown in illustration has been built by Bonnemaïson of Paris, for making comparative tests of aerial propellers.

Need for an Independent Body of Auto Engineers. Whether the automobile engineers will find satisfactory two distinct organizations, each under commercial and antagonistic restriction, or whether they will meet in the open arena of an independent organization in which the general advancement of automobile engineering without special reference to commercialism is the main object, may have to be determined by the mill of experience. That any organization which brings men together for an interchange of ideas and a discussion of a multitude of undetermined propositions, promoting an advanced engineering production and a uniformity of construction, is of immense value to the industry, needs no sustaining argument. It is equally apparent that the greatest benefit will be derived from the widest publicity of these deliberations, and any attempt at secrecy or exclusion has not only a belittling tendency to the participants, but defeats the whole object of co-operative investigation. Whatever temporary advantage might accrue to a manufacturer whose engineer may have solved one of the problems by himself is more than offset by a lack of knowledge of results secured by others.

The engineers are generally responsible not only for the success of individual enterprise, but for the industry as a whole. A purchaser of one imperfectly constructed automobile may injure the sale of any number of reliable machines. The field of undemonstrated experiment is as yet too large to warrant toleration by the broadminded engineer of any transient secrecy of construction or design, and a comprehensive interchange of ideas will be alike beneficial to the individual enterprise and the industry at large. While engineering sections of corporate combinations are doing much for their individuals numbers, it should

not preclude the establishment of a more comprehensive organization where qualification for membership should be limited only by engineering ability.

The Society of Automobile Engineers has been organized to meet this requirement. It now rests entirely with the engineers to determine if the organization shall survive, and supplement in preponderating degree the two restricted bodies now in existence. There is now need, indeed, for an assured open forum.

New York's Late Awakening. It has long been a current saying *ing to the Gasoline Cab.* that none but millionaires could afford to ride in a cab in New York, and though, like many other things, much exaggerated, still it is founded on fact. In no other city of importance in the world are cab fares so high, and, in consequence, cabs and cab riders so few. Paris, with a population of 4,000,000 in round numbers, can boast of something like 10,000 cabs constantly in service, while a like number are in storage according to the season, for the Parisian cab, like the American street car, changes winter and summer. Next to Paris London is the world's greatest cab center, but with a population almost twice as great, it has fewer cabs. New York is scarcely to be mentioned in the same category with many a city of the third or fourth class where cabs are concerned, for it is doubtful if more than a thousand or two are in regular service.

Radically differing traffic conditions coupled with New York's peculiar topography do much to explain this great discrepancy, but these and the vastly higher scale of expenditures prevalent do not shed any light on the fact that it costs five to ten times more to patronize a cab here than it does in either Paris or London, where the rate covers the transportation of one person or two for the same price. Within the past few months New York has had an awakening—she has come to realize of a sudden that the ancient and lumbering aggregations of old storage batteries and badly disaligned running gears that go by the name of electrics were cast on the scrap heap abroad two or three years ago and that light and speedy gasoline-driven cabs have not only taken their place, but also routed the horse cab to a considerable extent. Plans to do likewise here on a truly ambitious scale are now under way, and, if predictions be fulfilled, a year or two hence should see New York's streets populated with more gasoline-driven motor cabs than they have ever boasted of any kind.

It is sincerely to be hoped that the plans in question will not be carried into effect in the procrastinating and long-drawn out manner that has characterized the oft-heralded transformation of the Fifth Avenue stage line.

Aeronauts Are Becoming Exceedingly Optimistic. Aeronauts of the heavier-than-air school are in an optimistic frame of mind. Ignoring the alleged flights of the Wright brothers, three aeroplanists, with widely differing types of machines, have made public flights of sufficient length to far remove them from the running jumps which certain critics maintained was all that had ever been accomplished, or could be accomplished by the aeroplane. It is true that the flights have not been of great length—Santos-Dumont holds the record with 240 yards—but it must be remembered that we are working in an entirely new field and that frequently a machine is brought back to earth not because of its inability to remain longer in the air, but because its pilot hesitates to push his experiments to the danger limit. Santos-Dumont and his equally enthusiastic rivals are convinced that the Deutsch-Archdeacon prize for a flight of one kilometer in a circuit will be gained this year. Such a performance would prove irrefutably that the problem of aerial flight has been solved. The internal combustion motor has played, and will continue to play, an important part in this fascinating problem. Without the light multi-cylinder engine which Levavasseur has designed for aerial work, even the genius and intrepidity of a Santos-Dumont would be of little avail.

NAPIER COMPANY OF AMERICA FAILURE.

BOSTON, April 15.—Judge Dodge, of the United States district court, has appointed Arthur J. Farnsworth, vice-president of the Napier Motor Company of America, receiver for the concern, which was petitioned into bankruptcy last week by Boston creditors whose claims amount to about \$1,300. These creditors: the Vacuum Oil Company, whose claim is \$225; Ezra B. Whittier, who holds a claim for \$76, and William H. Wilkinson, whose claim of \$1,009, filed an involuntary petition in bankruptcy against the Napier company, and as the directors had admitted their inability to pay the debts and their willingness to be adjudged bankrupt, the court allowed the petition.

The attorney for the company stated that the receivership proceedings were brought about by reason of the company trying to do too much business on a limited capital. The receiver will make an immediate examination of the assets, and it is likely that the company will be reorganized. The company last week closed its salesroom on Boylston street, and last Wednesday night the large factory in Jamaica Plain was shut down. The company has been in existence several years and is capitalized at \$600,000, half common and half preferred stock. The paid-in capital was \$232,000. The liabilities are said to amount to about \$140,000.

ADVANCE GUARD LEAVES ON GOLD CUP TOUR.

To prepare the way for the Gold Cup tourists who will this summer travel 6,000 miles through Europe, Georges Dupuy left New York last Saturday with a 30-horsepower Stearns car provided by Wyckoff, Church & Partridge. The *Vaderland* will land Mr. Dupuy and his American automobile in Antwerp near the end of the month, and from there the party will proceed direct to Paris, leaving a few days later for a run round the entire district to be traversed by the main party. It will be a severe test of the quality of the machine, for the run will have to be accomplished as quickly as possible in order to get back to New York a little time before the departure of the main body.

Mr. Dupuy will prepare a guide book with the itinerary of the trip, having maps and descriptions of the various places of interest to be visited, together with a brief compilation of the idioms and common phrases of speech in the various countries.

Twenty-seven American cars have been nominated for the tour, while in addition to the entrants thirty-one persons have applied for seats in the competing machines. It is expected that there will be a considerable increase before the cars leave New York on June 1.

PENNSY'S TOLL ROADS MAY BE ABOLISHED.

PHILADELPHIA, April 15.—On Tuesday night last, without any fuss or feathers, the first step was taken in the Pennsylvania Legislature, now in session at Harrisburg, which may eventuate in the utter abolition of the hated toll-gate throughout the entire State within the next five years. On the evening in question Representative Minehart, of Franklin county, introduced a resolution, which was adopted, ordering the State Highway Department to at once begin inquiries to ascertain the cost of taking over and converting into State roads all turnpike roads on which tolls are now collected.

SUIT INVOLVING THE UNIVERSAL RIM.

AKRON, O., April 15.—F. A. Seiberling, as general manager of the Goodyear Tire & Rubber Company and for himself, has begun an important action in the United States Court in Buffalo against the Hartford Rubber Company, the Morgan & Wright Company, and the G & J Tire Company, all claimed to be members of the United States Rubber Company, in which Seiberling alleges infringement of his patent on his Universal rim for detachable tires. Mr. Seiberling claims exclusive rights of the sale by a patent secured by him in 1904. He alleges that this unlawful sale has been going on for a year.

DENATURED ALCOHOL NOT PROFITABLE AS YET.

TERRE HAUTE, IND., April 13.—Though the workings of any trust are hard to fathom and too much credence should, in consequence, not be accorded surface indications, it is reported that the Majestic distillery at this place, which was equipped by the alcohol trust to make denatured alcohol on a large scale, is still idle and there is little prospect of its starting up in the near future. The Industrial Company, formed by the trust to place the denatured alcohol on the market, is said to have found that the product cannot compete with gasoline as yet. Another trust plant, the Atlas distillery at Peoria, Ill., which was running in full blast, using 7,000 bushels of corn daily in the making of the denatured product, has been cut down to 2,500 bushels a day. It is thought that the Majestic plant will be allowed to remain idle until fall.

POPE COMPANY MAY MOVE TOLEDO PLANT.

TOLEDO, O., April 15.—The story has been floating about this city for the past three or four years that the Pope Motor Car Company contemplates moving elsewhere. Owing to the large investment the company has in this city in the line of buildings but little credence has been placed in the reports, the latest of which is to the effect that the concern would be moved to Elyria, Ohio. Color has been lent to the report on account of the labor troubles the firm has been experiencing for some time past.

Toledo has a chance to get the new plant of the Craig-Toledo Automobile Company, which is operating a plant at Dundee, Mich. Toledo and Detroit at present have the inside track, but the chances are greatly in favor of the latter, for Toledo has allowed several similar opportunities to go by the board.

FUTURE PLANS OF MORA COMPANY.

NEWARK, N. Y., April 15.—Owing to increased business, the Mora Motor Car Company has made arrangements for the erection of a modern two-story factory with an area of 30,000 square feet. The old shop will continue to be occupied, awaiting the erection of the new building, and later will be used as a paint shop and testing room. The new company is to be incorporated under the laws of the State of New York with a capital of \$750,000. The officers are: S. H. Mora, of Rochester, president; T. W. Martin, of Newark, vice-president; W. N. Freeman, secretary and treasurer. The board of directors are: J. R. McLaughlin, Canandaigua; T. W. Martin, Frank Garlock, C. L. Crothers, Newark; L. A. Parkhurst, Canandaigua; W. N. Freeman and S. H. Mora, Rochester.

SHOWS LARGER N. Y. REGISTRATION.

ALBANY, N. Y., April 15.—Secretary of State Whalen reports for the first quarter of 1907 the following receipts from the fees charged motor vehicle owners for registration and for licenses as compared with the same three months of 1906:

	1906	1907
January	\$10,485.06	\$10,477.52
February	9,395.07	10,776.50
March	3,083.35	4,154.20
Total	22,963.48	25,408.22
Increase for quarter..		\$3,444.74

MACK BROS. MOTOR CAR CO. JOINS A. M. C. M. A.

The American Motor Car Manufacturers' Association is continuing its strides in the line of increased membership as shown by the announcement that the Mack Bros. Motor Car Co., of Allentown, Pa., had applied for admission and was elected. Two other applications are now in the hands of the membership committee. The Mack Bros. Motor Car Co. makes the Manhattan sightseeing busses which are to be seen in almost every prominent city. It is now devoting a section of its factory to commercial trucks.

LATEST AUTOMOBILE DOINGS IN BRITAIN

By JOSEPH A. MACKLE.

LONDON, April 10.—Ever since the commencement of the motor industry continental motor manufacturers have found in Britain a ready market for their productions; France in particular having been able to dispose to John Bull of a proportion of its yearly output estimated at nearly fifty per cent. Of late, however, a marked change is apparent. Somewhat dubious of the advantages of a free trade system which enables the foreign manufacturer to dump his productions down without any charge, the Britisher is beginning to blow the "all-British" trumpet. As a result of this tendency the British automobile industry is experiencing a busy time, and prospects are extremely satisfactory. Continental manufacturers have been quick to recognize the trend of fashion, and in several cases have decided to open British factories for the construction of their cars. In this way the recently formed Lorraine De Dietrich, Ltd., has acquired the Ariel Motor Works at Birmingham, and will be turning out Dietrich cars in a few months. In like manner the Holland firm of Spyker, Ltd., and the Belgian Metallurgique Co. expect to have their British factories in full working order by the end of the season. Rumor has indicated the Winton Motor Carriage Co. as another addition to the movement, but except that a representative of the company was said to be seeking out a site for works last Christmas, nothing definite has transpired. Whether this last is correct or not, matters certainly seem to indicate that it will be necessary for any firm contemplating a big British trade to build, or at least to assemble, their cars over here in England.

Growth of the Motor Union.
